INDEX.

THE PHOTOGRAPHIC JOURNAL.

No. 85, Vol. VI.—JANUARY 1, 1859.

We trust that in making our appearance before our readers in a new guise, they may approve of the change that has taken place, and consider it an improvement as well as an alteration. Like the ladies of the present day, we have greatly enlarged our skirts—and like them, of course, must also regard the arrangement as an embellishment. Lest more engaging costume, however, should have so modified our appearance as to cause some risk of our being mistaken for a stranger, we must remind our readers that we are but "an old friend with a new face," and we hope not only to retain friendships already formed, but to convert acquaintances into friends, and strangers into acquaintances.

It has been a matter of very careful consideration with us how we may become still more useful to our numerous supporters than we have been hitherto—some of our intentions we have already indicated, and we have now further to mention, that we shall commence a series of initiatory articles; *first*, for the benefit of those still on the threshold of photographic fascination; and *second*, for more advanced students, of manipulatory details, descriptive of all the most approved methods of operating, as ascertained up to the present time: for we cannot but feel that photography of to-day is a very different thing from photography as it was a couple of years, or even one year ago—so many labourers are in the field, and so much has been achieved, that it is almost impossible for those not more than commonly interested, to keep pace with all the knowledge that has been acquired in the various ramifications of practical photography.

By this arrangement, it is hoped that all classes of our readers will find their tastes consulted—the novice and the adept, "the mere man of baths, and processes, and chemicals," as we have ourself been contemptuously styled—the man of science and the man of art—in short, we wish to make our pages like the fountain at which all may find something to slake their thirst; and our aim will be to endeavour to follow the wise steward, and "give all their meat in due season."

It has been suggested to us, that the single alteration which we have found it requisite to make in our designation, may possibly tend to cause some confusion with, and inconvenience to, the public, by confounding us with The *Journal of THE PHOTOGRAPHIC SOCIETY*. Now, although we do not think there is any fear on this head, the name of the Photographic Society being so very distinctive, and photographers, as a class, are men of discernment, yet always having hitherto maintained (and we trust *ever* to do so) most amicable relations with the conductors of the oldest publication devoted exclusively to our art-science, we therefore, unsolicited take the present opportunity of disclaiming any intention whatever, of an attempt to assume an attitude of hostility, or to deceive the public in any way. In proof of this assertion, we appeal to the number now before our readers as evidence that neither in size, style of heading, general aspect, or arrangement of matter, is there any resemblance whatever to the publications of the Photographic Society.

With regard to our Title, we have merely altered *the order in which the words were formerly arranged*, and added one or two more.

With a hearty wish that our readers may find the coming year prove a prosperous one, both photographically and otherwise, we pass to the "order of the day."

It appears to be a debateable question, whether of the twain, photographic engraving or photolithography, will be the first that will be practically applied to book illustration. As regards the former, in addition to the productions of Mr. Fox Talbot, now before the public, we have in another column a communication on the subject from our esteemed correspondent, Mr. Burnett. Now, although photometallography, as it has been termed, may, and probably will, eventually become developed into the more important operation of the two, we are strongly of opinion that photolithography, even in its present condition, is sufficiently advanced to render efficient service, with a very small amount of assistance from the hand of the draughtsman. At the last meeting of the Photographic Society, Mr. Malone expressed an opinion in accordance with our own; and since then, we have seen produced by an amateur photographer, acquainted with the lithographic art, as his first essay in this direction, a result that not only astonished us, but that requires only a few touches to convert it into an excellent picture. It must be borne in mind, that there is a vast difference between the assistance of a lithographer and that of an engraver—almost any one capable of handling a pencil can readily qualify himself for one, whilst this is far from being the case with the other.

It may be objected that we are now advocating the very thing we have formerly condemned, viz.—the "touching" of photographs; but we by no means assent to such an imputation; the cases are widely different. We object to "touched" photographs when judging of their respective merits; as obtaining credit upon false pretences. We do not advise or countenance in any way the attempts to impose upon the public proofs from photolithographic stones that have been submitted to the hand of an artist as *pure photographs;* but we do approve of the introduction of photography, as far as it can be rendered available, into the lithographic art. We may have more to say about this in a future number.

We were pleased to notice the other day a very useful application of photography. At the establishment of an auctioneer, and estate agent of the name of Engleheart, in Clement's Lane, London, are a number of paper proofs from negatives of various houses, &c., that are to be let or sold by the exhibitor.

No description, however minute, can possibly give so good an idea of the appearances presented as a single glance at these photographs; and we feel convinced, that a general adoption of the plan would be followed by an immense saving of trouble to the customers, and consequent increase of business to those who render such facilities.

At the meeting of the French Photographic Society, held on the 29th October last, MM. Davanne and Girard presented

the fourth part of their report on "*A General Study of Positive Proofs.*"

We have noticed the three earlier parts of this report in our last volume, and while fully admitting the careful and systematic method in which these gentlemen have conducted their investigations, and the highly interesting nature of the results, we cannot forbear remarking that no new facts appear to have been brought to light; but at the same time it is satisfactory to find, that the conclusions previously arrived at, and published by English experimentalists, have been fully corroborated. The present communication treats of—

1. The influence of the strength of the sensitizing baths on the proofs, and the impoverishment of the bath itself by frequent use.

2. The effect of a longer or shorter time being allowed for the paper to remain in contact with the silver solution.

3. The state of neutrality of the bath, as to its action on the finished proof.

With regard to the influence of the strength of the nitrate bath, the conclusion arrived at is precisely that to which we first directed attention, in a paper read before the Photographic Society nearly two years back, 5th March, 1857, and which was subsequently published in the third volume of the Journal of the Society, under the title, "*Further Observations on Positive Printing,*" and will be found at page 238. The result is materially influenced by the amount of free nitrate of silver. We quote the words of the report—"Thus, then, the strength of the bath exercises a very marked influence; as it increases it improves the print up to a certain limit in defining the outlines with greater sharpness, whilst as it diminishes, it equalises the tones at the same time that it brings with it a decided red hue."

A sheet of paper being salted with a solution of the strength of 25 grains to the ounce of water, and cut into *three pieces*, each piece being sensitized upon baths containing respectively 90 grains, 60 grains, and 40 grains nitrate silver to each ounce of water, the quantity of silver abstracted by each piece was ascertained, and found to be 0·876, 0·633, and 0·467 of metallic silver, or nearly in the proportions of 8, 6, and 4; but as the quantity of the chloride of sodium in each piece of paper was absolutely the same, this in presence of nitrate of silver in excess must have produced the same amount of chloride of silver, and consequently the varying results must have been due to the difference in quantity of *free nitrate of silver*, as admitted by the experimentalists. The conclusion is further corroborated, by exciting a sheet of salted paper upon a strong bath, cutting it into two pieces, and washing away the excess of nitrate from one of them.

The theory of action propounded is as follows—

"When a sheet of paper impregnated with a layer of chloride, mingled with free nitrate of silver, is exposed to the action of light, the chloride on the surface first blackens by reduction, but this chemical reaction sets free a certain quantity of chlorine, which attacks the nitrate in contact with it, forming fresh chloride, which blackens and is reduced in its turn, thus producing successive layers, and it is to this continuous reduction that the intensity of colour is at least in part due."

The following extract so completely agrees with our own remarks, *loc. cit.*, that we cannot forbear quoting it—

"For delicate negatives, producing habitually fogged positives, the bath should be stronger; for those furnishing strongly marked contrasts, it ought on the contrary to be weaker."

With regard to the *impoverishment* of the bath, although this fact was also notorious, the exact degrees of degradation under various circumstances had not hitherto been investigated; suffice it however to state here, that it is clearly traceable to the chloride in the paper which combines with its equivalent of silver, and the paper itself *then* absorbs an amount of the solution of the reduced strength. Albumenized paper lowers the strength, but not nearly in so great a proportion as when plain paper is employed, whilst gelatine and starch are nearly inactive. When salted albumenized paper is employed, the effect of deterioration is greater than with plain albumenized, but less than with plain salted paper. Increased time of contact between the paper and sensitizing bath acts like a stronger bath, because it allows of a larger amount of its absorption by the paper; and lastly, an acid or alkaline bath acts precisely in the same way as the same impurities in the chloride, of which particulars were noted recently in our last volume.

We often determine within our own mind, not to be surprised, happen what will; but alas! for all human resolutions, we constantly find that we have to resolve anew. We have heard so often of astounding discoveries in photography, and have been deluded into reading so many *new* processes which have turned out to be old acquaintances, that we fancied we were quite hardened to that kind of thing; but we certainly were not prepared for the cool manner in which one M. Asser, in a recent number of *Cosmos* puts forth as *new*, an almost verbatim translation of the Ink Printing Process, as practised by Mr. McCraw, lately published at the meeting of the British Association for the Advancement of Science, which process itself *is only a modification* of that of M. Sella. We expect next, that some Englishman will translate M. Asser, and come out with *another* new Printing Process.

In our report of the last meeting of the Manchester Photographic Society, vol. ii, p. 310, the President of the Society called the attention of the meeting to a very important fact that had been discovered by Mr. Young, viz.—that a collodio-albumenized plate having been exposed in the camera, may have the iodide of silver dissolved out with hyposulphite of soda before development, and that the picture may be subsequently developed in ordinary daylight. We find from subsequent inquiry, that the operation does not succeed without the use of albumen; nor does it answer if the iodide be removed by aid of cyanide of potassium. This is a subject well worth pursuing, and we strongly advise those of our readers who are working the collodio-albumen process in any form, to follow it out.

We think the phenomenon admits of a very simple explanation. A compound of some sort, probably of two kinds, is certainly formed between albumen and nitrate of silver, which is sensitive to the action of light, and blackens under its influence. This compound superposed on the iodide of silver, is readily impressed, but unlike the iodide, has itself undergone a chemical change; hence, when the latter is removed by the solvent, the chemical change induced in the compound of albumen and nitrate of silver, is carried on still farther when the necessary ingredients, viz., nitrate of silver and a de-oxidizing agent are supplied.

We are aware, that many consider the question of any chemical change having been effected in the iodide of silver after the import of light, as still undecided; others again hold an opinion, that this change does undoubtedly occur, but in this we are not disposed to acquiesce, and consider that the weight of evidence evidently tends rather to show, that no change of a *chemical* nature occurs in the iodide of silver; but that its office is somewhat analagous to that of platinum, in a finely divided state, when converting the vapour of alcohol into acetic acid; this acting however as an absorbing medium for actinic influence. We merely throw out this suggestion as one that strikes us as explanatory of the effects, and by no means hold ourself to it as a well-considered opinion, but are quite ready to give it up if a better explanation can be found.

The Architectural Photographic Association have opened an Exhibition at the rooms of the Society of Painters in Water Colours, Pall Mall East, which we notice more fully elsewhere.

PHOTOGRAPHIC PAPERS.

One of the greatest difficulties the photographer has to contend with at the present day, is in the papers manufactured expressly for photographic purposes. Of Foreign papers, we have *Papier Saxe*, Canson's, and Marion's; of English, there are Hollingsworth's, Harrison's, and others. Although the pulp of the papers of these different makers is in all respect the same, being composed of linen and cotton rags, yet very different photographic properties are produced from them, in consequence of the sizing being different. English papers are, for the most part, sized with gelatine, while those of the Continent are sized with fecala, or starch and resin soup. Now, the sizing greatly influences the colour of the proof; papers sized with gelatine give very red hues in the printing-frame, while those sized with starch are sepia or violet: still the *quality* of the sizing does not influence the colour of the proofs so much as the *quantity*; for by increasing the quantity of starch in the paper, hues as red as those from gelatine may be obtained.

The sizing not only makes the proofs more vigorous, but also makes them sharper and more delicate. A proof taken on unsized paper, is dull and leaden in hue, and in every respect repulsive. If but slightly sized with albumen, the unsized paper is but little improved: strong starch produces bright orange hues, and if the unsized paper be immersed in a strong solution of gelatine (5 per cent.) fine reddish hues are produced.

The quantity of sizing contained in the paper as delivered by the manufacturer is insufficient for photographic purposes; for proofs taken on plain paper, although very pleasing and satisfactory in an artistic point of view, lack transparency in the shadows, and that general brilliancy of tone which is indispensable to suit the popular taste. However, at the present time, the extra sizing is carried to excess, and except in stereoscopic pictures should be avoided. For portraits, landscapes, architectural subjects, &c., paper prepared with a mixture of albumen and water, in equal parts, has quite sufficient surface and gloss to bring out all the detail, and at the same time to secure adequate transparency in the shadows.

In fact, the higher albumenized paper now sold is to be regarded with suspicion, as the very high glaze is not due to pure albumen, but to an admixture or adulteration, either dextrine or gelatine; the presence of the latter is recognised by the chocolate red colour of the proofs when removed from the pressure frame; and if the wet proofs are allowed to dry while in contact, they adhere together and are spoiled.

Oxide of silver, in combination with gelatine, and exposed to light, becomes an insoluble black varnish, which reflects a golden red hue; but when the combination is first made, the compound is of a mahogany red colour. These facts explain the causes of the variety of hues given by papers sized with different materials. If the paper be unsized, then the salt of silver enters into combination with the fibre of the paper, and the silver tends to decompose and reduce itself; or perhaps, as suggested by Schönbein, ozonized oxygen plays a part in this change. But in the case of sized paper, the particular affinity of the sizing material for the silver overcomes the disposition of the salt of silver to combine with the paper, or to reduce itself, and forming the compound spoken of, the chemical action is not exercised *on* or *by* the paper itself; the picture therefore requires both greater sharpness and the red hue due to the sizing material. Whatever the kind of sizing employed, or the quantity, it does not appear to have any influence upon the rapidity of printing; other things remaining the same.

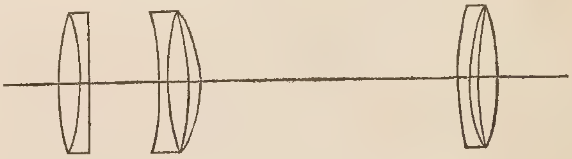
Nor does the thickness of the paper appear to have any influence upon the result, beyond what is due to the greater abundance of sizing it contains; but thick paper is easier to manipulate, although more liable to tear while wet. From what has been stated, it appears that it is a matter of indifference what paper is used, provided it be not used plain, but sized with albumen, dextrine, gelatine, or starch. Some attention must be paid however to the sizing strength of equal weights of these materials, as the results will be materially influenced thereby. Of all the sizing materials, albumen, more or less diluted with water, is to be preferred.

THE PETZVAL AND VOIGTLANDER CONTROVERSY.

Immediately after the introduction of the new landscape lens by Professor Petzval, it was asserted by M. Voigtlander, that the form was *not new*—that he had made for the learned professor a lens upon the same principle no less than seventeen years before. Upon this assertion being denied, he subsequently declared that he still had in his possession the original drawing and formula in Professor Petzval's own handwriting.

A certified literal translation of this document has been deposited with Messrs. George Knight and Co., of Foster-lane, Cheapside, London, which appears to us to completely verify the assertion of M. Voigtlander, and we consider it of sufficient interest to lay it before our readers, which we are enabled to do by the courtesy of Messrs. Knight.

When inspecting the document, we were also shown a meniscus lens, forming the second part of the middle combination in the diagram, which had been accidentally made of crown instead of flint glass, by M. Voigtlander, and which—although it, of course, disturbed the union of the chemical and visual foci—did not affect the perfection of the image, when the necessary allowance of distance to correct this was made. Hence it is contended by M. Voigtlander, that slight variations in the curves to suit the particular density of the different glasses employed do not interfere with the *principle* of the lens, and that the mere reduction of the *diameter* of the second pair of lenses is the only change that has been introduced by Professor Petzval recently into the original formula.



In stating our opinion, that M. Voigtlander is correct in his assertion, it does not detract from any merit due to Professor Petzval for the calculation of the data for the construction of the lens; nor does any body question this point.

The following is a copy of the document mentioned above—

First double lens, consisting of a double-convex lens of crown glass, and a double-concave lens of flint glass.

$r_1 = 36{,}4''' = 3''\ 0{,}4'''$ $r_2 = -28{,}5''' = -2''\ 4{,}5''' = r_3$ $r_4 = 300'''\ 25''$

*$r_1 = 3{,}00''$ $r_2 = -\ 2{,}37$ $r_4 = 25''$

The dispersing lens of compensation, consisting of a double-concave lens of crown glass and a convexo-concave lens of flint glass.

$r_1 = -86{,}4''' = -7''\ 2{,}4'''$ $r_2 = 50{,}8''' = 4''\ 2{,}8'''$ $r_3 = -126{,}3''' = -10''\ 6{,}3'''$ $r_4 = -3{,}69''' = -3''\ 0{,}9'$

*$r_1 = -7{,}11''$ $r_2 = 4.32''$ $r_3 = -9.03''$ $r_4 = -3.11''$

The converging lens of compensation, consisting of a convexo-concave lens of flint glass and a double-convex lens of crown glass.

$r_1 = 72{,}1''' = 6''\ 0{,}1'''$ $r_2 = 25{,}3''' = 2''\ 1{,}3''$ $r_3 = 31{,}3''' = 2''\ 7{,}3''$ $r_4 = -102{,}8''' = -8''\ 6{,}8''$

We certify this to be a copy of a Drawing, and a literal translation of a German document, presented to us by M. Voigtlander.

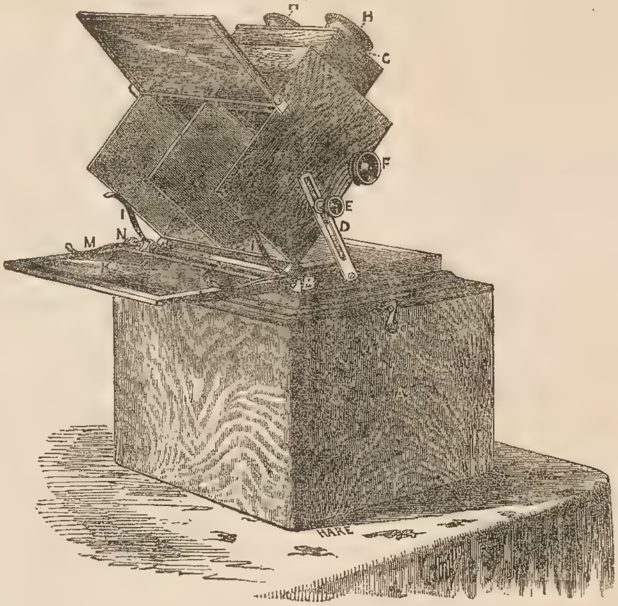
Dr. AUG. ELHDE, *Prof. of Mathematics and Natural Philosophy, at the Collegium Carolinum.*
Dr. HERMAN SCHEFFLER.

These signatures verified, Brunswick, Nov. 12, 1858.—WILLIAM HUGH, *Public Notary.*

* The figures in these two rows are in pencil in the original.

NEW ACHROMATIC STEREOSCOPE.

We have been favoured by Messrs. Smith, Beck & Beck, with the following description of their Stereoscope, which we give in their own words —



In contriving our improved Achromatic Stereoscope, we have had the following objects principally in view —

The application of achromatic lenses, to improve the definition, and to correct the colour produced on the margins of objects by single lenses.

An arrangement to suit any one who has the sight of both eyes.

A stand upon which the instrument can be placed in any position more especially convenient, when the person is seated at a table.

A method of holding the slides, which will allow them to be placed and replaced easily, and without danger.

An illumination to be varied at pleasure.

And lastly, a case to keep the whole from dust, injury, or exposure.

We have been more especially led to the construction of this instrument, by the beauty of those photographs now published, which, from the high position they hold, either as works of art, or as exact transcripts of places of interest, and of the works of nature, will as certainly carry the stereoscope beyond a scientific toy — the point at which it first started, as they will deservedly rescue it from the degraded position it is almost threatened with, by the "got up slides" of gaudy groups and indecent figures.

The Stereoscope as taken out of the case (A) is upside down, but when turned over it will stand on the table, or on the case (as in the figure above) if secured by the hooks (C), it has a joint at (B), and can be fixed in a vertical, horizontal, or any intermediate position, by the brass arm (D), which is tightened up by the small milled head (E).

Two other positions in which the instrument may be required— the one when horizontal and the person is sitting, the other still more raised for a standing position — can be obtained by an additional stand, which is also made available as a cabinet for the slides. The height necessary for these purposes is about ten inches, but in other dimensions, the cabinet may be proportioned to the number of the slides or other requirements.

By these means alone, the Stereoscope can be used at the four followng elevations, viz. —

When standing. When with the case. When alone and on the cabinet. When with the case and on the cabinet. Any intermediate positions can be obtained by the before mentioned joint at (B).

The two milled heads (F) are for the adjustment of the focus. Those who have "long sight" will require the lenses farther from the picture, and as the full extent of the rack-work is frequently insufficient, this distance can be increased, by drawing out the lenses in their fittings at (G); the reverse is of course required for short sight; while many of those whose vision is unaffected in either of these ways, will be able to see well throughout the whole range of adjustment.

Every stereoscopic slide consists of two pictures, but they must unite and form one in the instrument. This will generally be the case when the two arrows on the brass rims (H) point to each other; but there are some kinds of vision, and occasionally errors in the slides, which require one or other of the lenses to be slightly turned round in its fitting at (G) — the method of mounting admits of this, and also of their being easily taken out for the purpose of wiping, *which should be done frequently*.

The slides are placed outside and under the two springs (I).

The illumination requires alittle care. For daylight it is best to face a window. Artificial light should also be in front; but then, it must be remembered, that the distance makes a great difference in the intensity; and also, that a variation in height, as when ordinary candles are burnt, requires a constant alteration in the position of the reflector or the instrument; this will not be the case with gas, or oil lamps, and two of Palmer's candles will answer every purpose.

For transparencies, the door (O) is closed, and the illumination is effected by a movable reflector (K) — packed in the case — but which, when in use, is held by the two brass arms (L) and springs (M), a hinge at (B) affording the necessary variations of position. The silvered or other side, is used according to circumstances; but occasionally, some kind of tinted paper or other reflecting substance is preferable for giving a tone to the picture, whatever it may be; it has only to be placed above the reflector, and under the springs, or in the place of it if of a sufficiently stiff material.

For opaque slides, light is thrown upon the picture by the mirror (O) on the inside of the door, which will remain in any position in which it is placed.

GOLD TONING ON ALBUMENIZED PAPER.

Mr. Hardwich has communicated to the Photographic Society of London some observations on photographic printing, in which he deprecates, as unjust, the prevalent disposition to decry the methods of toning and fixing now in use. In skilful hands, doubtless, the methods in vogue are fully adequate to secure permanency, but the host of pictures "fading away" that meet us on every hand, prove too forcibly that some radical defect exists, if not in the formula at least in the manipulation. It is better to seek to improve the former than the latter; therefore Mr. Hardwich proposes an improved toning by *alkaline* chloride of gold. This mode of toning is adapted for any kind of sensitive paper, but its peculiar value is seen in the case of albumenized paper, which is sometimes difficult to colour by the *sel d'or* process, and even in the ordinary fixing and toning bath of hyposulphite of soda and gold, does not attain to an agreeable tone, unless the bath be kept in a very active condition. Make a solution of chloride of gold, one grain to the ounce of water; take of this

Solution of chloride of gold..........	1 fluid drachm.
Sesquicarbonate of soda........	1 drachm.
Citric acid................................	20 grains.
Water (pure).....	12 fluid ounces.

This solution will not keep when mixed, as it gradually undergoes a change, becoming colourless, and toning more slowly. It is not clearly understood what part the citric acid plays in this mixture; in a warm alkaline solution of chloride of gold it throws down an indigo blue deposit of metallic gold.

A strongly albumenized paper is to be preferred for this method, especially one that prints rather red, otherwise the gold is liable to yield too blue a colour. A rich velvety appearance is promoted by using a sensitizing bath of full strength: sixty grains of silver to the ounce for a paper salted with a ten grain salting solution.

The prints may be kept for a few hours after removal from the printing frame, but it is best to tone them at once. Wash them in two or three changes of water until milkiness disappears; they may be left in the water until it is convenient to tone them, which is done as follows —

Mix the ingredients of the formula given above in an evaporating dish, and when effervescence ceases, place a spirit-lamp beneath, and raise the temperature, with constant stirring, to about

120° F., which is indicated by the steam beginning to rise, and a bluish discolouration, due to commencing reduction, is seen. The lamp must now be removed, else much of the gold will be reduced, changing the colour of the fluid to an inky black, after which it will be nearly useless. Filtering is unnecessary.

This warm liquid is poured into a flat dish, and the prints are put into it, two or three at a time. A little discolouration of the toning solution may be disregarded, since it is caused by a quantity of gold quite microscopic, and will not injure the whites of the proof. Keep the prints constantly moving, and watch the changes of colour. The first two or three may perhaps be toned in about five minutes; but as the liquid cools down, and the quantity of gold decreases, twenty minutes or longer may be allowed. The time, however, is greatly influenced by the quality of the paper; English papers strongly albumenized requiring a longer action.

If the prints are removed from the toning bath as soon as the blue colour of the gold is seen, they will generally change in the fixing bath to a warm hue of brown; but when left for two or three minutes longer, the deeper tone acquired is permanent. The proofs are ready for fixing when they cease to appear red by transmitted light. Over-printed proofs yield the blackest colours, because they may be kept in the gold a longer time without losing the half tones. It is not advisable to attempt to obtain pure white and black tones on proofs printed from feeble negatives, for unless there be a perceptible amount of bronzing, the deep blacks cannot be obtained on albumenized paper.

Each grain of chloride of gold ought to tone six or seven prints, 5 × 7, and two or three of 10 × 12, which is rather more than the number yielded by the same quantity of gold in the *sel d'or* process.

Fixing — The proofs must be rinsed on both sides upon removal from the gold bath, and fixed in the following solution —

Hyposulphite of soda	6 ounces.
Water	1 pint.
Carbonate of soda	½ ounce.

This solution will keep many weeks, and imparts a slightly improved colour after being much used. The carbonate of soda is added to prevent the fixing solution from acquiring sulphurtoning properties to an injurious extent. The time of immersion is from ten to fifteen minutes, or until no mottling appears in the proof when held against the light. The proofs are washed in the usual way.

PHOTOGRAPHIC ENGRAVING ON METAL PLATES.

By C. J. Burnett.

From a paper read before the Edinburgh Botanic Society, March 1858, given as apparently superior to that of Mr. Fox Talbot then published (and it may possibly be in some respects fully equal even to his new one).

I first describe the process in the simpler state, in which it is sufficient for copying pen and ink, or pencil line drawings of plants, scenery, and other objects, wood-cuts, line-engravings, and every thing else consisting of lines alone; and next consider the additional contrivances necessary in etching from true photographs of plants, scenery, natural objects, architecture, paintings, Indian ink drawings, and every thing in fact *not* made up of lines equally translucent. Where a drawing is on thin paper, we may, of course, print from it directly, but generally, of course, the plan is to take first a negative and then a positive to print from.

1. Coat your plate of zinc, iron, steel, copper, or other metal, with the sensitive mixture of bichromate of soda, potash, ammonia, or other bichromate, chromic and uranic, or ferric nitrate, or other salt, with gelatine, gum, meta-gelatine, or allied substance.
2. Dry the plate gradually or by the aid of heat.
3. Print in pressure frame.
4. Connect the plate, metallically, by means of a screw clamp or other arrangement, with a plate — say the same size — of silver, platinum, platinized silver, or other less oxidable metal, and coat the *back* of the first plate with varnish.
5. Plunge the two plates into a weak solution of sulphuric, muriatic, nitric, or other acid, or etching fluid, watching carefully the process, and putting into a weaker or stronger etching bath if required.
6. Wash off the remaining gelatine mixture.

Instead of coupling the plates in the manner now described, we may connect the plate (first varnished on the back) with the wire of *one* (the oxidizing) pole of a galvanic battery or cell, and a plate of silver, copper, or other less oxidable metal, with the wire of the *other* pole, and plunge the two plates, opposite each other, into the etching bath, containing a solution of, say, sulphuric, muriatic, nitric, acetic, tartaric, chloric (oxalic ?) or other acid; or of sulphate of soda, muriate of soda, nitrate of potash, chlorate of potash or of soda, acetate, oxalate, or tartrate of soda or other, salt—the strength of action being regulated either by the strength of the battery (which may have its metallic elements raised or depressed in their cell or trough), or by the strength of the etching bath. If the plates are connected as first described, it is, of course, by the latter that we regulate it.

N.B.—The object of the galvanic current connexion which I have introduced, is to prevent the production of a deposition of gas-bubbles on the metal plate being etched. It will be evident, that these bubbles being evolved *under* the gelatine, would be apt to cause a separation or blowing up of it at the surface of the metal. It might be fancied that the washing away of the soluble gelatine before etching, generally recommended in such processes, would remove this difficulty; but besides other objections to such washing, it does not appear that it can answer any such purpose, except in the case of a picture composed entirely of lines, and those lines all of the same depth of blackness. Any attempt to remove the gelatine or other mixture, before etching, is, therefore, it appears not only useless but likely to interfere seriously with the delicacy and uniformity of the etching. It will be seen at once by any one having the slightest acquaintance with galvanic action, that the gas is on this plan evoked on the less oxidable metal, or at the opposite pole instead of on the metal being etched.

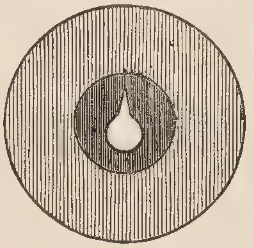
As the plan of applying resin-powder *above* the gelatine or other coating before etching would not be likely to answer,* we may apply it below, as suggested by Mr. Fox Talbot, or *far rather* follow out a plan or plans suggested to me by the shade of fine gauze, mentioned by Mr. Talbot as adopted by him in one of his old processes. I would recommend a set of fine *crossed* or uncrossed lines or dots, photographically or otherwise produced (we may get very fine lines or dots by photographing, on a *smaller*, from those accurately *drawn* on a *much larger* scale); they may be either on a separate glass, or on the print itself *from* which we are printing on to the metal, or a little charcoal powder, lycopodium, or other fine powder may be sprinkled on the back or front of the print, or on a separate glass to be placed above it. The same set of lines, if on a *separate* glass, may answer for printing from any number of different negatives, and we may make glasses or paper for the same purpose, by photography, from a charcoal or other powder-sprinkled surface.

This same mode of procuring grain will answer equally as well for photolithography, or photoxylographic blocks, with gelatine and bichromate, or any of the allied mixtures already alluded to.

ON THE FORM OF THE APERTURE IN THE DIAPHRAGM OF A LENS FOR LANDSCAPES.

By Wm. Ross.

I have noticed sundry intimations in the *Journal* of some methods of contracting the aperture of a lens, one or more of them being obviously more costly than the majority of persons using the camera can afford to supply themselves with. I am a great advocate for every one being able to supply the occasional deficiences of his apparatus by his own ingenuity, and therefore send you the description of the diaphragm and aperture I have now used for several years. The diaphragm is itself cut out of thin cardboard, of such a diameter as will easily slip into the tube in which it is to be used. In the centre of it I describe a circle, of a size adapted to the focal length of the lens, as modified by the objects in the view to be taken. If all are beyond the longest conjugate focus of the lens, then the quantity of light to be admitted is the only consideration which ought to enter into the determination of the size or shape of the aperture; and as the circle contains the largest area of all the figures, this would appear to be the best form where all the extreme rays are equi-distant from the axis of the lens.



When some of the objects are nearer the lens than in the above

* Mr. Fox Talbot's new process has shown that I was quite mistaken in supposing that there was any impossibility in this, but I leave it as written, and still it would appear to me that some of the plans here specified (founded, as I have mentioned, on another of Mr. Fox Talbot, to whom we owe so much) are likely to prove more convenient and give equal if not more, satisfactory results than any aquatint application to the plate.

case, a much smaller aperture is required, which of itself involves a longer time of exposure to the light to produce the impression. Now every one of any experience knows that the upper parts of all objects are much sooner impressed than the lower portions, and as this is the case, a modification of the aperture should be made to meet this inequality, either by excluding some of the rays from the upper side, or by permitting more of those from the lower portions of the object to get access to the tablet.

This I accomplish by not cutting out the whole of the circle in the middle of the diaphragm, but I cut the aperture of the shape of a Florence oil flask. The position in which this diaphragm is to be placed in the tube will depend on whether it may be most convenient to place it between the lens and the view to be taken, or between it and the tablet on which the impression is to be made. In the former case, the small end of the aperture must be placed upwards; whereas in the latter case, *i.e.* with the diaphragm *inside* the lens, the wide end of the aperture should be uppermost. By this means also, clouds may be taken without being overdone while the landscape is being impressed, as is so often the case. I use the former method with an ordinary camera on the ground; but in my *waggon camera* I use the other, because when I wish to change it I cannot conveniently reach the outside of the lens, which is about 8½ feet from the ground. In my sciopteric camera (see *Liverpool and Manchester Photographic Journal*, vol. 1, new series, p. 49). I also use the diaphragm inside the lens, and it is of the same shape as the above figure, only longer and of much less width in proportion to its height. By the way, I see some persons are now engaged in England in reinventing the sciopteric camera, and after that happens, Mr. Seeley of New York will "*invent and introduce*" it without delay, as he does most other things which promise to be of use in the art.

Meetings of Societies.

Blackheath Photographic Society.

An ordinary meeting of this Society was held on Monday, the 20th ult., J. Glaisher, Esq., President, in the chair. The minutes of the last meeting were read and confirmed.

S. Knill and H. Williams, Esqrs., were duly elected members of the Society.

Mr. Heisch called the attention of the Society to the subject of mounting photographs. He stated, that though he still thought India rubber in many respects the best substance for the purpose, because it not only had no action on the photograph, but protected it from the effects of the bleaching substances sometimes left in the mounting board, yet that it had some disadvantages—it was troublesome to use, and if the drawings were brought too near a fire, it sometimes gave way. He was then driven to the use of glue, or some other kind of gelatine, which answers very well, but requiring to be used hot, it is difficult to get it evenly spread on a large drawing before it chills, unless it be made so thin as to soak into the paper, and thereby warp the mounting board as it dries. Having lately been using meta-gelatine as a preservative for dry plates, he was struck with its excellent adhesive properties, and tried it for mounting; it answered well, stuck as firm as glue, and could be applied to the largest surface with the utmost deliberation. The solution he employed was made by placing one ounce of pianoforte-makers' glue in ten ounces of water, with from forty to fifty minims of concentrated sulphuric acid; when the glue is quite swelled, which takes three or four hours, it is heated and kept near the boiling point for two or three hours longer, the acid saturated with carbonate of lime (common whiting does very well), and the solution filtered hot; two ounces of spirits of wine is now added, and the whole made up to twenty ounces. If not quite clear, the solution will now filter easily at a temperature of about 80°, while at from 60° to 65° it is sufficiently thick, not to swell the paper to which it is applied enough to make it warp the mounting board. The solution will keep for months.*

Mr. Melhuish exhibited some transparent stereographs from negatives, recently sent him by F. Haes, Esq. The negatives were taken in intensely hot weather, in Cairo, on plates prepared by Dr. Hill Norris, before Mr. Haes left England. Mr. Haes stated, that the time of exposure was much longer than would have been required in this country.

Mr. Knill exhibited some large photographs which he had recently brought from Rome, and Mr. James a very beautiful photograph from a drawing.

The meeting then adjourned.

* Since the meeting of the Society, Mr. Heisch has found that the heating with the acid must not be too prolonged, that in fact a small quantity of gelatine must be left unconnected, otherwise the solution runs quite limpid at all temperatures.

Chorlton Photographic Association.

The monthly meeting of the above Society was held on the 9th ult., at the Chorlton Town Hall, when the President of the Society, Professor Roscoe, B.A., Ph.D., addressed the meeting "*On the Measurement of the Chemical Action of Light.*"

The learned Professor exhibited an instrument contrived for the purpose, the test being the action of light on a mixture of hydrogen and chlorine gases, the amount of chemical action being ascertained by the quantity of hydro-chloric acid produced, the susceptibility being so great, that an atom of oxygen being amongst the prepared gases caused the working to cease.

The preparation of the gases was explained, and the mode of registration elucidated.

The instrument required a considerable time to reach its maximum of action, but after three days, the actinism could be read off as from a thermometer. The spectrum was produced with a prism, by the aid of the oxy-hydrogen light, and the Professor's remarks thereon received the warm approbation of the meeting.

Professor Roscoe also presented to the Society two pamphlets, "*On Photo-Chemical Researches.*"*

Some prints in carbon were exhibited by Mr. Hooper, which were said to be the best of the kind yet seen, but the peculiar colour was objected to. Mr. Hooper remarked, that the carbon could be coloured, by adding some pigment to produce another shade of black. Some prints were also exhibited, toned with carbonate of soda and chloride of gold, which were much admired from the absence of the unpleasant colour, often produced by hypo-sulphate of soda and gold toning. The whites of these were pure and the blacks brilliant.

Mr. Fawcett proposed, that the best thanks of the meeting be given to the President, for his able address, and for his sympathy with the Society; and also for the donation of the works, which he hoped would be carefully perused by the members.

The President in thanking the members for their attention to the address he had the honour of delivering, said it would afford him pleasure to be of use to any member who experienced difficulty in a chemical point of view, and would be glad to answer questions put to him at any time.

Macclesfield Photographic Society.

The members of this Society, the establishment of which was noticed in our April numbers, have continued to meet during the season; and on several occasions very interesting papers have been read, some of which have appeared in our columns.

A numerously attended special meeting was held on the 14th inst., for the transaction of business connected with the practical working of the Society, at which, after hearing the statements of the Secretary and the Treasurer with regard to its present position and prospects, some minor changes in its arrangements were agreed to, and a committee was named to carry out an object towards which some steps appear already to have been taken, viz.—the organization of an Exhibition of Photographs, &c., under the auspices of the Society, in connection with the Annual Exhibition about to take place at the Government School of Design. Pictures for exhibition will require to be forwarded to F. M. Mercer, Esq., the Secretary, and the Exhibition itself will be probably opened during the first week in January.

Exhibitions.

ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

The managers of this Association, which was formed for the distribution among its subscribers of photographs *illustrative of architecture*, have opened an Exhibition at the Gallery in Pall Mall East, in order to give the members an opportunity of selecting such works as they may prefer, and doubtless, also, to enlist new subscribers.

Besides the ordinary catalogue, an *illustrated* one is also published, containing six photographic plates, on which are represented very reduced copies of the whole of the subjects (with their catalogue numbers), comprising the collection, thus enabling those members, who from absence from the metropolis or other cause are unable

* The subject of these pamphlets was noticed in our last volume.—Ed.

to attend, to make their choice. Each proof has attached to it a relative numerical value, members being entitled to receive for their subscriptions a number of proofs, not exceeding a certain aggregate amount of these arbitrary numbers.

The ostensible object of the Association is clearly not understood by our excellent contemporary, the *Athenæum*, as will be readily gathered from the following extract of a notice of the exhibition, which appeared in its pages last week—

"Why the figure photographers should recede from the architectural photographers we cannot see; but we suppose these secessions are *protests against error*, and that somebody has done wrong and compelled the planting of this fresh art-colony at a time of the year when any thing new in art is always welcome, as long as it is not connected with 'the old Christmas trick,' which shopkeepers seem to use, as by common consent, to work off their faded stock."

By the way, the above is rather an unfortunate illustration, as regards "the old Christmas trick;" for about nine-tenths of the pictures exhibited, however meritorious they may be, are very old acquaintances of ours, and doubtless also of most other photographers.

We cannot very clearly perceive in what way photography is advanced by this Association, neither is the advantage to the members themselves very apparent, as most of the subjects can be procured direct from the artists themselves, or their publishing agents, at a cost certainly not exceeding that now charged for them without each person being compelled to take (or to pay for) any thing he does not want.

The disadvantage to photography is more potent, firstly, in the presumption set afloat that its votaries are a very disunited set; secondly, in the fact that a collection of merely architectural subjects must and does present a very monotonous effect; and thus an erroneous impression is likely to gain ground with the public that a photographic exhibition is a very "slow affair," for it can hardly be expected that mere sight-seers will take the trouble of ascertaining the cause of its sombre aspect.

A criticism of such a collection as that now under consideration, is of necessity more than usually liable to be influenced by the personality of the critic, and his figurative "point of view," of which in the present case there are at the least four, viz.,—the architectural, the antiquarian, the artistic, and the manipulative. As we write however for photographers, and for them only, it is as a photographer we shall deal with the contributions.

One of the remarkable features is the absence of frames, properly so called, the subjects being arranged against the walls, and the edges covered by horizontal and perpendicular slips of gilt beading, —an arrangement that not only economises space, but we should think money also, and, in our opinion, well worthy of the consideration of managers of these exhibitions. It is a modification of a measure adapted by the Leeds photographers, at the late meeting of the British Association for the Advancement of Science, and was described at the time in our pages.

Another unusual arrangement consists in the collection in separate masses of the productions of each contributor, and in this the advantages and disadvantages seem to be pretty equally balanced, for though it tends to the unity of design, it also adds materially to the monotony; in the present case, perhaps more than in an ordinary collection, where all classes of subjects, instead of one only, are admitted. The happy medium was hit upon at the exhibition of the Photographic Society (London), in January 1858, at the South Kensington Museum, where masses of works, the production of one artist, were relieved by the occasional commingling with those of many other operators; thus unity of design and variety of contrast being both duly represented.

Of the 120 views in Rome, contributed by Macpherson, we have no remarks to make interesting to photographers: they are all well known, and as photographs have no particular merit. The antiquary and architect will probably be delighted with them; our own choice would fall upon No. 110, "Window in the house of Lucrezia Borgia," as presenting something more of the picturesque than the generality of them.

Cimetta has thirty-four illustrations of Venice, of large size, 21 by 17 inches, but scarcely one of which we should care to possess, for not only are they of a very unpleasant brown tone, but most if not all of them are distorted in consequence of what is generally known by "cocking the camera." Had they been taken on a smaller scale, this defect might very probably have been avoided.

Robertson and Beato exhibit about thirty views of and around Cairo, of about one-third of the size of the last mentioned, and among them are several very interesting illustrations of street architecture, valuable in every collection. We notice particularly Nos. 190, 197, 204, 212, 214, and although in some of these a slight haziness is apparent near the basements of the houses, owing evidently to the constant movement of figures in the way, it is not sufficient materially to interfere with the general effect.

Lonsada has a score of Spanish subjects, but the whole of them are so deficient in sharpness and general manipulation, that they are only fit for *stop-gaps* for an architect, until he can procure better representations of the objects delineated—photographically, they are absolutely valueless.

Cade of Ipswich, and *Cocke* of Salisbury, contribute between 50 and 60 subjects from Oxford, Cambridge, Ipswich, Salisbury, &c.

We are somewhat surprised at the absence of *Delamotte's* Oxford illustrations, and *Fenton's* Cathedrals; surely, they ought to have found an honourable position in an architectural collection.

Baldus has a dozen of his views in Paris, Caen, &c., but these are too familiar to photographers to need further comment.

Of Frank Frith's beautiful Egyptian and Scotch scenes we need say but little, having more particularly noticed them on previous occasions. There is one curiosity, however, that must not be overlooked, a Panorama of Cairo, measuring 8 feet 6 inches by 20 inches high. This is of course produced by joining several proofs from as many negatives, but the junctions are in all the cases well managed, and the printing of each piece toned to the same hue.

There is one point in which the managers of the Association have been "wise in their generation." We mean in retaining the services of Mr. Bedford, to produce expressly for the Association a set of negatives of Tintern Abbey, Raglan Castle, &c., in number about thirty. It is amongst these, Frith's, and some few others only, that any members, not architects, will be sure to make their choice. Certainly, as pictures, those named are the most desirable in the room.

Of Mr. Bedford's we admire especially No. 313, West Front of Tintern Abbey, and 321, West Door of the same; 323, Chepstow Castle; 315, the Donjon, Raglan Castle; and 317, the Entrance Gate of the same. Nos. 336, 337, 338, 340, 341, Subjects at Canterbury, are also very beautiful, and executed with the usual skill of this artist.

We shall be somewhat curious to learn how far this exhibition will prove popular, after the opening of that of the Photographic Society in Suffolk Street, which is now shortly to take place; for, if report speaks truly, the occupation of these rooms in Pall Mall by the Association was accomplished by aid of what we suppose we must call "successful diplomacy," at the expense of the Photographic Society. However, be that as it may, we rather think that a preference will be shown where the attractions are likely to be more varied than in the present case.

NOTES ON THE EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF SCOTLAND

[From a Correspondent.]

Edinburgh, December, 1858.

Happening to be in Scotland in December, as I was piloting my way from the station to some respectable hotel, two or three ragged urchins badgered me to buy from them the morning paper, which I did, more to get rid of their pertinacity than any thing else. On opening the paper after getting to my hotel, the first thing that caught my eye was the advertisement of the Exhibition of the Photographic Society of Scotland. This was more than I had bargained for in my journey to the north, but too good an opportunity to let slip; so I discharged my more urgent business, determining to make the most of my short stay in Edinburgh. I have resolved to send you a few notes to keep you *au courant* with the times on the art I love so much, but have time to practice so little.

The Society's Exhibition Room is situated in George Street, about the centre of the New Town, in a very eligible locality, consisting of one large ornamented saloon, with two screens across the room, erected for the purpose. I find a goodly number of pictures from English artists (somewhere about 300, or nearly a third part of the whole), have found their way north from F. Bedford, Barnes, Caldesi, Claudet, Delamotte, Davies, Frith, Herring, Lyte, Maull and Polyblank, Melhuish, Morgan, Mudd, Pouncey, Robinson, and last though not least, our old friend, Rejlander, whose mag-

nificent landscape of Loch Katrine surpasses anything I have seen as a photograph from nature, in or out of Scotland; it is No. 639.

"Where wild rose, eglantine, and broom,
Wasted around their rich perfume,
The birch-trees wept in fragrant balm,
And aspens slept beneath the calm,
The silver light ——————"

It is by far the largest and finest composition in the saloon. How soft and placid is the water in the fore-ground; the bold, gray lichened crags in the middle distance, whose base is richly clothed with dwarfed birch and oaken copse, to the water's edge; the sweetly subdued and distant hills, miles away, with the light playing through the clouds, softening and illuminating the entire piece! This glorious picture is the centre piece of one of the screens, and is worth coming to Scotland to see, to those who have time and means at command. I even forgive the badgering newspaper boys who annoyed me, and will be on good terms with the whole race till next Christmas at least. I find a few more pictures of this ingenious and ambitious artist, which I have not seen before.—No. 427 is an interior group, entitled "The Scripture Reader." In a humble cottage sits a young person, a female missionary, reading the Bible to a quaint-looking old woman, who, busy spinning, has stopped her wheel; the old man is seated on the stair-case in wrapt attention, listening to the reader; in the foreground is a dog (a remarkably good sitter for his portrait) and basket, with the neck of a bottle obtruding, doubtless containing a cordial to refresh some way-worn, weary spirit. The young woman's over-dress and bonnet are carelessly laid on a chair, and the open Bible spread in her lap. The shelf with domestic utensils, and the German clock, with other accessories, render this a most inviting study. The grouping is excellent, and implies a master's hand.—No. 510, is a portion of "Two Ways of Life," which as a whole was turned to the door a year ago, by the fastidious Scotch committee, and which, I am informed, disrupted the Society, dividing the professional and amateurs into two distinct parties. This photographic picture, as a whole, is unsurpassed in Europe; but, clipped into little bits, tells no tale: this is the industrial or right hand group. Whether this has been received and shown this year in order to mollify the keen and bitter feelings evoked by its rejection, I cannot tell; but the committee seem either to be changed, or something "has come o'er the spirit of their dream," for I find, in perhaps the most prominent place in all the Exhibition (No. 283), an entirely *nude* Venus de Medici, by Alinari, (does being an Italian make the difference ?) nude from top to toe, and I cannot understand upon what ground or principles men act, who hang and prominently exhibit the one while they reject the other, unless it be by way of condonement for the egregious blunder stumbled into on that occasion, which gentlemen connected with the art and locality inform us was far from being homologated by a large portion of the Society, even of the remanent members.

"—————— But to confess their error,
That were nobler still."—

Perhaps Mr. Rejlander's sympathies will be touched when he is informed they were a committee of BACHELORS. He has not, however, given them the option of choosing and rejecting this year, as I observe by the catalogue all his pictures exhibited seem to be the property of others.—No. 505, exhibited by Mr. Laurie, is another of Rejlander's composite pieces, "Judith and Holofernes." I think the heroine in this piece is rather too good-natured looking to have been a murderess; and yet she has a bold, defiant bearing, as she stands with the weapon in the one hand and the head of Holofernes in the other. The drapery of the figure is well executed.—No. 67 is a portion of an intended larger work, entitled the "Seven Ages" of Shakspeare."

These are pictures in which there is a breadth and harmony that might be envied by a "Harvey," even though in that gentleman's estimation, "Photographers are not artists," but all artists (that is R.S.A's.) are photographers (?) You should commend to your friend Rejlander, as a text book for his next great picture, the "Pilgrim's Progress;" and in doing so have little fear of his habiting honest John Bunyan in the costume of Italian Piferari, as was done by an artistic Royal Academician some years ago, and exhibited at the Royal Scottish Academy.—Mr. Robinson, of Leamington, has also been trying his hand at composition from various negatives, somewhat less ambitiously than Rejlander. No. 219 to 223 are five pictures, entitled "Fear," "Vanity," "The Model," "Devotion," and the "Minature," with the same figure in all, evidently being *his* model, for she also appears in "Fading Away," and some others, by this artist. In these five he has endeavoured to catch the delicate and subtle expression of the passions, not easily attained, even with skilful posé, drapery, &c.

I think him more successful in the "Red Riding Hood" series, an ancient nursery epic, where four of the chief incidents of that charming story are well depicted. In the first there is the mother, a bustling, active-looking woman, preparing the present, the little "pot of butter," &c., to be carried by the child to gran'ma, and is strongly contrasted with the simplicity of the little messenger. In the next she has arrived at the cottage door (too little of the cottage is seen): having knocked, she is invited to enter in a strange, hoarse voice. In the third the artist places her standing at the head of grandmamma's bed, amazed and frightened at the change undergone since her last visit; the wolf being habited in the old woman's nightcap, trimly put on, with a partially-opened mouth, showing the long, large, white, pearly teeth; entirely covered with bedclothes save the head, enough to stupify and confuse the philosophy of an older and wiser head than that of the simple child. In the fourth the frightened little woman has returned to her mother, and having related the story of her adventures, is seen thanking her Maker at her mother's knee, for having been preserved from being eaten up by the horrid wolf. There is a large amount of skilful grouping and arrangement in the details of this series, which render each one a fascinating study.

No. 644, "Fading away," is a subject I do not like, and I wonder Mr. Robinson should have allowed his fancy to fix on it; it is a picture no one could hang up in a room, and revert to with pleasure. I am certain this artist is competent to do something better; his conception and rendering of character is good, and, with more practice and a proper choice of subject, will yet shine lustrously in the photgraphic firmament.—Fenton's "Reverie," (No. 149), is also something akin to this class of pictures. No Scottish artist exhibits in, or seems to have turned his attention to, this branch of the art. Perhaps the most curious and interesting pictures to photographers, are some seascapes by Mr. Kibble, a Glasgow amateur, who exhibits 22, if I mistake not, mostly, if not the whole, by the collodio-albumen process. Of these, No. 164, "Express Steamer," is a magnificent production, though the picture is small; it is taken in the *fortieth* part of a second, and developed in *ninety hours*: the rolling clouds are a beautiful transcript of nature. The steamer (of which you have a profile) is running very quickly, leaving a deep furrow in the waste of water, heaving with agitation, as she is forced onward by the propulsive steam. This is verily a triumph of instantaneous photography, of which I had no conception dry collodion was capable. I trust, as this gentleman is an amateur artist, that he will publish his developer, which will be certain to give an impetus to the dry process. His other pictures, of which there are both landscapes and portraits, are remarkably fine.—Mr. Wilson, of Aberdeen, has also several sea and cloud pieces by collodion, equal, in my estimation, to any I have seen of Le Gray's. The "waxed paper" seems also to be improving, and gives good results, where collodion would be too quick and set before it had been sufficiently exposed, in corridors, such as Roslin Chapel, of which there are several views by Mr. Herries and W. D. C. Those of Mr. Herries are very good, but I rather suspect, on close examination, that the bars or beads holding the squares of glass have been deepened and strengthened, if not in some parts entirely ruled in. The windows of W. D. C. (No. 203,) is evidently doctored, and that with a rough hand.—There are also some good pictures of buildings and landscapes by Mr. Zeigler. (No. 112) "The Grange House," and (No. 171) "Cottages at the Grange," are good specimens; the latter is a first-rate production, well chosen, sharp and clear in the shadows, with reflected light twittering from the sheen, glossy leaves of the climbing ivy.

Mr. Raven is also an adept in manipulating this waxed paper process, and exhibits a large number (thirty two) from the district of Pau, in France, and the Pyrenees—fine large views, 10 by 12 or thereabouts.—No. 216, "Pierrefitte," is a noble specimen, with a conical mountain in the distance, and the town spread in the foreground at its base, sharp and clear.—242, "Pau," is also very creditable to this artist: in short he has been very successful; but it would be impossible to go over them in detail, the more especially as I intend to allude to some others in the same locality, by Maxwell Lyte, which are superb. However, you have now as much as you will be able to find space for in your next number.

SEL D'OR.

[Many of the pictures in this exhibition, noticed by our correspondent, have been described by us in our last volume, and we are glad to find our favourable opinion of them corroborated by others. We allude more particularly to those of Rejlander, Robinson, and Wilson.—ED.]

New Processes.

PAPER POSITIVES BY MODIFICATIONS OF M. SELLA'S INK PROCESSES.

In our report of the meeting of the North London Photographic Association, which took place in November last, a discussion upon new methods of printing by means of iron salts was recorded, and some very promising specimens by Mr. Hannaford were noticed. We have recently been favoured by that gentleman with some still better specimens, and the following outline of his mode of proceeding, which although not yet perfect, evidently shows capabilities that are, we consider, certain to be developed by a little further investigation. At present the lights are not quite free from a *tinge* of blue (it is but a tinge), and the half tones, though somewhat "*shy*," do exist. We have a promise of more elaborate details for our next, in the meantime we give a sketch of an

IRON PRINTING PROCESS.

By Michael Hannaford.

The paper is sensitised by being floated on a solution of bichromate of potassa, ammonio-citrate of iron, gum arabic and sugar, and is then exposed under a negative in the usual manner.

Taken from the printing frame, the picture is immersed in water to soak out the bichromate of potassa, iron, &c., not acted on by light. The print can now be toned to resemble almost any tint of the ordinary silver process, by using, firstly, the salts of the various metals, gold, silver, copper, manganese, uranium, &c.; and secondly, gallic acid or tannin. Ferro cyanide of potassium and gallic acid gives Prussian blue; ferrid cyanide of potassium and gallic acid blue-black; and gallic acid alone a good sepia tint.

The above so closely resembles in principle a process with which we were favoured by Mr. Burnett, some months ago, that we cannot forbear publishing it now, although we were anxious to make further experiments upon it first.

INK PROCESS.

By C. J. Burnett.

1. Paper Preparation — With a solution containing say *eight* to twelve parts by weight of *ammonio-ferric-oxalate*, and either *four* parts of *bichromate of ammonia* or *one* part of *chromic acid*.

N. B.—The paper may either be plain or albumenized, and a little gelatine may be, in either case, dipped in the sensitizing solution. Prepare dry, and keep *very carefully in the dark, and even the solution must not get the slightest gleam of light.*

2. Expose in pressure-frame not too long.

3. Wash very carefully in a good many waters containing (*most* or *all* of them but the first), a very minute quantity of citric, acetic, oxalic, or other acid, bi-tartrate of potash or other acid salt. The last water may be distilled water or *neutralized* rain-water. I have also tried several of the ammonia salts in washing.

4. Development by a solution of gallic or tannic acid (a mixture of the latter with ammonia, or ammoniacal, or other alkaline carbonate) or by prussiate of potash, by the one, and then further by the other (say by the prussiate first and then by gallic acid).

N.B.—A little of the acetate or ammonio-oxalate or other vegetable salt of copper may be substituted for *part* of the ammonio-ferric oxalate (particularly with a view to the *prussiate of potash developement*), or bichromate of *copper* may be substituted for the *bichromate* of *ammonia* (or a little oxide or chromate of copper dissolved in the solution of chromic acid, &c.)

The albumen protects the chronic acid from a *too easy* reduction by the paper, and the gelatine mixture helps still farther to keep it on the surface. Try also $N O^5 \times Fe\ ^2O^3$ or $Cl^2\ Fe$ instead of ammonio-oxalate.

By *substituting* a *copper salt entirely* for the ammonio ferric-oxalate we get a copper print (developing in this case by prussiate of potash) and toning by iron if we do not wish a red-brown print, as for withered foliage or ferns. *Sulphate of copper and bichromate of potash or of ammonia were the basis of the cuprotype* or copper process published during the last year (see *Photographic Journal* of August), by which I got some *very fine* and highly promising prints, particularly that which I sent up to Mr. Crookes [see my letter in the *Journal of the Photographic Society*, 1857] requesting to *give one of them (a view of an old gateway,) in my name,* to the Photographic Society, it being the best I had produced, and a very fair print of good dark purple black, perfectly pure in the lights. Though I never received any acknowledgment of its receipt by the Society, I can hardly doubt Mr. Crookes's having given it, so that you can probably see it in their rooms.

My impression is, that that process promised fully as well as any ink-process yet published.

I have not ascertained the correct proportion in the substances for paper preparation here, and you may frequently enough find others quite superior, still the quantity of chromic acid must be kept down *very low in proportion* to the ammonio-ferric-oxalate — and you *must not over-expose* the prints.

The oxalic acid is decomposed by the chromic acid.

Ammonio-citrates, or ammonio-tartrates, or *acetate* of *ferric* oxide might probably be substituted for the ammonio-*oxalate.*

Letters to a Young Photographer.

No. I.

My Dear Eusebius —

I hasten to comply with your request, that I should give you the benefit of my experience in the delightful art of photography; and although I may be able to save you much annoyance and disappointment, do not suppose but that you must unavoidably buy a good deal of experience for yourself, and perhaps at a very high rate too. For knowledge in photography is gained only by experiment, and experiment implies failure; but failures give experience, and the more experience the nearer we arrive at perfection in art. Many there are, who think photorgaphy can be taught like cookery, and that a recipe can be given for making pictures as well as pies; but give a recipe for making a pie to one having no preconceived notion of pie-making, and doubtless, the recipe would fail in such hands. So in photography. How many there are who in their simplicity think it only necessary to obtain a camera and chemicals, then buy a shilling manual, and they are set up, full-fledged photographers. But how soon all their aërial castles vanish into thin air, or tumble to the ground. Those, my dear Eusebius, who begin with taking pictures, commence at the wrong end — begin, in fact, where they should leave off. As the aim and end of the photographer is to obtain good positive pictures, it is evidently of the first importance that he should ascertain what constitutes a good picture. This knowledge can only be arrived at by great familiarity with negatives, good and bad, such as the printing of positives affords. Having ascertained what are the qualities in a negative that yield the best results, you will then have before your mind a clear and well-defined object, which will render your operations with the camera more satisfactory, because, instead of being contented with any thing of a picture, so it be one, you will at once reject as abortions all those which fall short of the standard you have set up. Begin, therefore, your photographic career, with positive printing.

Your outfit need not cost much. You had better prepare your paper for yourself. You will acquire delicacy of handling and touch — a very important accomplishment in photography. You must provide yourself with a large dish to float your paper in, and this may be either of porcelain or of wood, lined with glass. Another dish of smaller size, but as large as the largest size paper you propose to make use of, must be reserved exclusively for the silver solution. At first you will find it very inconvenient to manipulate whole sheets of paper, so you had better cut the sheets to one quarter, or one-third, or one-sixth, and then the floating will be more manageable. The room where you propose to albumenize your paper, should be kept very clean and free from dust or soot. You will require some arrangement of laths, &c., to pin the paper to while it is drying. The table at which you operate should be opposite to a good light, and some contrivance must be made to catch the albumen that drips from the sheets when suspended. Take any number of eggs, and breaking them carefully, pour the whites, free from any admixture of the yolk, into a clean bason; add about equal quantity of water, and put the whole into a large bottle, so as to about one-half or two-thirds fill it. For every pint of the mixture of albumen and water add six drachms of hydrochlorate of ammonia and one drachm of solution of ammonia. Agitate the whole for an hour or more, until the fluid becomes a mass of froth, and let it subside for twelve hours, then strain it through a sponge in a glass or earthenware funnel. Pour a sufficient quantity of this into a dish placed level, and remove all air-bubbles from the surface, then float the paper upon it in the following manner —

Take the sheet by the corners diagonally, and bring them towards each other, so as to make the paper curve; let the middle of the sheet first touch the surface of the fluid, and then gradually let the paper fall gently upon it: see that no bubbles adhere to the surface of the paper. Let it float three or four minutes, then lift it out, without allowing the back to become wetted, and drain it into a dish or pan, so as to recover the albumen, then pin it up by one corner to dry. The room in which this operation is performed should be made as warm as possible.

Photographic Glossary.

Aberration — The aberrations with which we are most concerned in photography, are *spherical* and *chromatic* aberrations. The word is used to signify a wandering from the true path or place. *Spherical aberration* is that distortion of true lines in an image, consequent upon the reflection or refraction of the rays by a spherical surface. It is not possible to construct a single lens with spherical surfaces that will give an image entirely free from aberration; but it may be so much corrected, by forming a lens of two or more glasses of different forms and qualities of glass, as to be practically nullified, as is seen in the various modifications of the "orthoscopic" lens.

Aberration, Chromatic — White light is composed of rays of six or more different colours, each of which has a different degree of refrangibility, so that when a ray passes through a simple lens, each of these coloured rays has a different focus along the axis of the lens, which constitutes chromatic aberration. As these rays have very different chemical powers, it is important to the photographer that this aberration should be corrected, which is done, he rendering the lens ACHROMATIC.

Accelerators — Various substances which are added to iodide and chloride of silver, with the view of quickening the action of light, and thereby accelerating the production of an image. Their use has for the most part been confined to the Daguerreotype process, in which *bromine* performs a very important accelerating influence, reducing the exposure in the camera from minutes to seconds; but this substance has no such influence in the other processes where moisture is present, as in collodion, albumen, or the paper processes.

Acetic Acid — Familiarly known as vinegar, which is very dilute acetic acid mixed with many impurities. Pure acetic acid is extensively used in photography, mixed with pyrogallic acid in the developing solution for negative pictures. Glacial acetic acid is the most concentrated form of this acid. Citric acid may be advantageously substituted for acetic acid in photographic processes. *Acetates* are combinations of acetic acid, with bodies of opposite qualities, called *bases*. Thus acetic acid added to soda forms acetate of soda.

Achromatic — devoid of colour. As in photography it is of the utmost importance that the visual and chemical foci should coincide, it is the object of the optician to produce a lens in which this result is obtained. It is accomplished by forming a compound lens of glasses of different degrees of density, and by a proper adjustment of their curves, by which the "wandering" coloured rays composing the image are collected together, in, or nearly, one plane, thus producing achromatism. It is a subject attended with many difficulties, and it is even asserted that it is impossible to make the chemical and visual foci coincident, except for one given condition.

Acid — Acids are substances which are generally sour to the taste; and which change vegetable blue colours to red. Acids are organic and inorganic. They enter into chemical combination with alkalies or other bases, and form bodies with entirely different properties to either, as when sulphuric acid is mixed with magnesia, sulphate of magnesia or epsom salts is the result. The principal acids used in photography are the acetic, citric, gallic, nitric, and pyrogallic.

Actinism — It has lately been discovered, that a ray of light possesses three distinct powers or properties, viz.: — the *luminous* or light-giving, the *calorific* or heating, and the *actinic* or chemical. It is, therefore, the actinic element of a ray of light that effects the remarkable changes in the substances submited to its action, which constitutes photography. Actinism exists chiefly amongst the violet and blue rays, and scarcely at all in the red and yellow rays.

Actinometer — An instrument for measuring the intensity of the chemical or actinic rays of light. Such instruments are also called *photometers*.

Affinity — A power possessed by chemical substances, of combining with certain substances in preference to others. Thus silver has a greater preference for chlorine than it has for nitric acid; therefore, when nitrate of silver is placed in contact with a chloride, it is decomposed, and chloride of silver is formed.

Albumen — Familiarly known as white of egg. It is extensively used in photography, both in the negative and positive processes. In the former, as a vehicle for coating glass plates with iodide of silver, a process invented by M. Niepce de St. Victor, hence called the Niépcotype process. In positive processes, albumen is used for coating the surface of paper, by which means proofs of greater delicacy and brilliancy are obtained than upon plain paper. It serves also as a varnish. Albumen forms a chemical compound with silver, called albuminate of silver, which is highly sensitive to the action of light. It is coagulated, or rendered insoluble in water by various substances, such as corrosive sublimate, nitrate of silver, &c.

(To be continued.)

New Books.

Lay's Photographic Almanack and Ready Reckoner for 1859.

A VERY useful compendium for the photograper, consisting, in addition to the Calendar and usual Almanack matter, of a collection of very useful tables, &c., a summary of the progress of photography of the past year, improved processes, new apparatus, obituary, &c., &c. The tables showing the relation between the size of object and image, focus and lens, and distance of object, are alone worth ten times the price of the Almanack, — a photographer would save that much time upon any occasion in which he essayed to take a view of a building.

Foreign Correspondence.

Paris, December 16, 1858.

I GLADLY respond to your invitation, to keep you informed of the progress of photographic science in this capital; and I am fortunate in being able to occupy my first letter with matter both curious and interesting. For the past month, practical photography has been a vain struggle against gloomy skies and foggy atmosphere (for we do have fogs here sometimes), consequently we have found ample leisure to pursue the theoretical.

Foremost in interest and importance, stands the third memoir on the action of light, by M. Niepce de St. Victor, which was read before the *Académie* by that honoured veteran in science, M. Chevreul. It is difficult at first to recognise the vast importance of this new communication, for it is given in a manner so free from pretension, that there appears nothing extraordinary about it. But when you ponder over it, you gradually become aware, that these discoveries extend the domain of photography to an unexpected and unhoped for extent, which becomes almost as vast as chemistry itself, as it is shown that every chemical action is capable of affording photographic effects; for take any soluble substance whatever, and impregnate a sheet of paper with it, and then expose it under a negative to the light; after sufficient exposure, move it to a dark room, and develope by some re-agent, capable of transforming the soluble substance upon the paper, and a visible picture results; the chemical action becomes photographic! The same result follows if the order of proceeding is reversed; that is, if the developer is first applied to the paper, afterwards exposed to the light, carried into a dark room, and then treated with the soluble substance with which the paper was impregnated in the first instance, the picture will appear as before. This result follows, not only with the salts of silver, but also with those of gold, with iodide of potassium, the prussiates of potash and of iron, the tinctures of turnsol of curcuma, &c., which become sensitive agents adapted to exhibit the effect of the action of light. The bearing of these researches upon the art of dyeing is very important; for we can now investigate with a sure clue the phenomena of fading colours.

M. Chevreul called particular attention to two applications of chemistry to photography. A sheet of paper impregnated with a strong solution of nitrate of uranium, exposed to light under a negative, afterwards washed in pure water, then treated with bichromate of potash, yields a picture of great beauty, resembling drawings in red chalk, and which becomes permanently fixed by washing in water. If the paper is treated with prussiate of iron instead of prussiate of potash, a very remarkable blue picture is

produced. In fact, pictures may be obtained of every colour and hue imaginable. Another process, which promises the most important results, and yields very fine positives economically, either black or brown, is as follows—a sheet of paper is impregnated with gallic acid, exposed under a negative to light, then treated with iodide of potassium, and afterwards with nitrate of silver: a very vigorous positive is the result.

Here are suggestions enough to employ the whole legion of photographers for the next six months; and now that positive printing occupies so much attention, we may expect very important changes in the method at present in vogue to follow very soon. I should add, however, some of the conditions under which these photographic phenomena present themselves.

In order that light may act effectively upon organic or inorganic substances it is necessary that they be in a state of minute division; and that an *organic* substance be present when inorganic matter is submitted to the action of light for a picture to be produced. When we operate with paper, of course the organic matter is present, but the experiment with the same chemicals, when performed upon glass or porcelain, does not yield a picture, although the inorganic substance is acted upon by light. Many substances, when acted upon by light, become insoluble to a remarkable degree, and they can be washed in quantities of water without dissolving. Moisture, especially when combined with heat, quickly destroys the action acquired by solarization, and renders them again soluble. In like manner, heat and moisture, greatly accelerate the reduction of metals under the influence of light.

As only the first part of this memoir was read, we may expect further revelations before long.

M. Roussin has suggested a new method of obtaining cyanide of potassium, in large quantities, by the double reaction, at high temperature, of nitrate and acetate of potash. At first sight it would appear that the acetate could be replaced by acetic acid, but such is not the case, for when the latter is substituted for the acetate, cyanide is formed in very small quantities or not at all.

An improved method of toning positive proofs, which has the recommendation of simplicity and excellent results, has been proposed by M. Bayard, at a meeting of our Photographic Society. It is as follows:—In a pint of water dissolve fifteen grains of chloride of gold, then add it in small quantities at a time, while stirring, to the following solution — water one pint, hyposulphite of soda eighty grains, hydrochloride of ammonium, or chloride of sodium, half an ounce. This mixture assumes an orange-red colour, but after a time becomes clear and colourless; it is then fit for use. It is better to wash the proofs from the free nitrate of silver when removed from the frames, but it is not indispensable. As soon as the proofs have acquired the desired tone, they are to be removed to a fixing bath, composed of hyposulphite of soda five drachms, water thirty-three ounces: this bath effects very little change in the tone of the proofs.

The third exhibition of the French Photographic Society is now postponed until April next. Works intended for exhibition must be forwarded not later than the 15th March next, addressed to the Secretary, agent of the Society, M. M. Laulerie, No. 11, Rue Drouot, Paris. The Society invites the co-operation of the photographers of all nations, so that a truly *universal* exhibition may be presented. The works sent for exhibition will be submitted to the examination of a jury nominated for that purpose.

Photolithography has of late made such progress in the hands of M. Poitevin, that four different illustrated works are now being printed by his improved method, viz., Labarthe's *Recherches sur la peinture sur èmail au moyen âge et dans l'antiquè: Serapium de Memphis:* Lottin de Leval's *Voyage in Egypte*, and Penguilly's *Description du Musée d'Artillerie.* Carbon printing is chiefly in the hands of Messrs. Salmon & Garnier, who lately exhibited some new specimens of their process on paper and on glass. Two of these were obtained from plain paper negatives in ten minutes, and in the sun's rays: the same effect is produced in thirty or forty seconds, with a transparent negative. Two others were obtained from glass, upon an albumen stereoscopic negative, the sensitive solution on the glass plate being made strongly ammoniacal, and diluted with a certain quantity of alcohol. Another proof also on glass is enamelled; that is, rendered ineffacable by heat, from the enamel-powder being dusted on the proof instead of carbon.

The quality of the proofs obtained by Messrs. Salmon & Garnier is remarkably fine; even when examined by the microscope, no *grains* are visible in the parts forming the picture, — nothing but a pure tint. Of the practicability of the process for commercial purposes, that is, in despatch and moderate price, it is shown, that every proof, on paper or glass, sensitized, exposed to light and carbonized, requires only ten or twelve minutes to complete it. The application of the carbon is so simple as to be easily performed by ordinary workmen, or even boys and girls. For my own part, I do not consider carbon printing successfully arrived at, until the carbon is effectively applied in suspension or solution; and nothing short of this will satisfy public demands.

J. P.

[In printing the letter of our correspondent, we think it necessary to observe, that we by no means adopt his sentiments. — Ed.]

Correspondence.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, George Shadbolt, 2, *Upper Hornsey Rise, N., London. All* Advertisements *and* Letters *on the* Business *of this* Journal, *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

RESTORATION OF FADING PROOFS.

To the Editor.

Sir—I should feel much obliged if you could tell me of any way of restoring paper positives which have become yellow and are fading from time. I have one (the only print existing, the negative being destroyed) which I should like if possible to preserve: the features are rather indistinct, and it is very yellow. Thanking you for the reply to my last, I remain, &c. W. B. C.

Liverpool, 10th December, 1858.

[If we had a *certain* remedy for the fading alluded to, it would be a very great advantage, but we are not actually in possession of one. The following method is *sometimes* successful, but the fading described being due to sulphurization we are not confident of its answering in the present instance:—

Add a few drops of tincture of iodine to water until it is of a full sherry colour—float the faded proof thereon for from ten to fifteen minutes, wash well in water and hang it to dry. When nearly dry, or quite so, immerse in a saturated solution of gallic acid to which a few drops of solution of nitrate of silver has been added, say five drops to each ounce, the proof to have been previously exposed to light, when sufficiently developed wash in salt and water, and subsequently in plain water, and lastly iron with a pretty warm iron.—Ed.]

DRY PROCESS WANTED.

To the Editor.

Sir — Would you kindly favour me with an answer, in your very excellent *Journal*, to the following question? What is the best of sundry processes, viz.— the most convenient, quickest, and that which gives the best results, and what is the average length of exposure? I have made numerous attempts at the waxed paper process, and have not at all succeeded. One objection, the removal of which would be a great *desideratum*, is, that *I don't get any pictures*, or if I do, it is only the bare outline of the sketch. I have tried various ways and formulœ, but without success, exposing from five to forty minutes, to different objects. By the merest chance I once got one of the best waxed paper negatives I ever saw, but could not accomplish the same feat a second time; unfortunately the negative was destroyed. With apology for trespassing on your valuable time, I am, yours, &c.

December 20th, 1858. A. H. JACOB.

P.S. — Would you kindly give me a formula for a good toning bath.

[Either the collodio-albumen process, Dr. Hill Norris' gelatine process, Fothergill's, or else a modified oxymel process, by A. Whitham, will answer your purpose. You will find full particulars of Fothergill's process at pages 115, 144, 193, 207, and 241 of our last volume; and of Whitham's at page 301. It is not improbable that a deficiency of nitrate of silver solution, when developing, may have been the cause of your want of success with the waxed paper, as the exposure would appear to have been sufficient. You must remember, that without free nitrate of silver there is nothing to produce the picture. For toning bath see Mr. Hardwich's paper in the present number.

CAUTION RELATIVE TO THE CARE OF NEGATIVES.

To the Editor.

Sir — The truisms, "The longer we live, the more we learn," "Experience teaches wisdom," "We pay for learning," &c., all come into my head when on the point of telling you that you may let others know how, in one instance, they may save themselves from *paying for learning.* Hear my tale. I have several good plates — 12 × 14 inches — that have cost me some trouble and great expense, belonging to the background of a new composition. I took particular care of them, so that a few days

ago, I gathered them up and placed them in a box, a few *yards* from the stove in my glass room. Yesterday I wanted two of them, and though varnished, they were more or less peeling off, the result of numerous beautiful arborescent cracks.

We have had a week of fog, and the last two days heavy rain — so the warm room by day, and cold and damp at night and morning, has made the covered glass box into a most perfect and delicate steam or vapour bath, and doing the work gently and constantly, it made it more completely so. I warn others not to lock their plates up in deal boxes, where they are liable to great and sudden changes of temperature. Fifty other plates standing about have had no other damage than dust.

I shall be but a poor contributor this time to the exhibition. I have but *one* thing that has not been at my publishers and in their windows; for as soon as I make a good thing I send it off, trying to let it pay its own expenses. I intended this last fortnight to do something, but, from the constant fog that has enveloped us, I have been unable to carry out my intentions.

The only thing I have that has not been *out*, is a very good photograph from a sepia drawing after Raphael, that I lately made for H. R. H. the Prince Consort; yet, during the year, I have made many pretty good studies, but I could not afford to keep them locked up.—I am, yours, &c.

O. G. REJLANDER.

Wolverhampton, December 18, 1858.

[" *Nemo mortalium omnibus horis sapit*" — but when a wise man does commit a blunder, he usually rectifies it, as far as possible, immediately upon discovering it. Such has been the conduct of the council of the Photographic Society; and we trust that, ere these lines reach the eye of our correspondent, he will have been made aware that the objectionable regulation has been rescinded.—Ed.]

PHOTOGRAPHY FROM A BALLOON.

To the Editor.

Sir — I see it announced in a photographic publication, that it is proposed to extend the use of the camera to a new field of action, with the view of obtaining photographs from a considerable elevation above the surface of the earth, by means of balloons. As a photographer, I feel, that while we should do all in our power to extend the range of the art by suggesting new objects for its application, or communicating our own experience to each other, it is equally our duty to give any information which may tend to prevent photographers wasting their time and energies in directions in which our experience tells us no good result can be expected.

Having had a good deal of experience in ballooning, I beg to say that it will not be possible to use a camera or lens of any kind from the car of a balloon, for the simple reason that the machine is never in the same position two seconds together, and not only so, but the difficulty is greatly increased by the fact, that those in the car have no means of knowing the direction which the motion may take. It would thus be impossible for the most expert eye to follow it. Even in the case of a captive balloon the same objection applies, though in a different way. It is true that balloons have been used for purposes of observation in warfare; but the conditions necessary in the two cases are widely different.—I am, yours, &c. CHAS. W. SMARTT.

Pentonville, December, 14, 1858.

EARLY PHOTOGRAPHIC EXPERIMENTS.

To the Editor.

Sir — In your report of the proceedings of the Historic Society of Lancashire and Cheshire, in your last publication, Mr. J. T. Towson observes, "that in the early days of photography, say in 1838-39, when he and four others (Sir John Herschell, Mr. John, now Sir John Lubbock, Mr. Fox Talbot, and his friend Mr. Robert Hunt), were the only followers of the science in England."

I take leave respectfully to inform him, through the medium of your publication, that the art was early practised here by me, which the enclosed letter, taken from a Belfast paper, will more fully show, and the publication of which in your pages will still be of interest to photographers:—

" *From Belfast News Letter of September* 20*th*, 1839.

"The Daguerreotype. — On this curious subject, the following interesting letter has been addressed to us by Mr. Beatty, the well-known engraver of this town. We have also received the specimen to which he refers, and the effect noticed by him is extremely singular.

'To the Editor of the *News Letter*.

Sir — Being occasionally engaged since the announcement of M. Daguerre's extraordinary invention of fixing on silver plate or copper the minute images of external objects, produced by means of the camera obscura, after a number of experiments, I was somewhat surprised to find, that in using silver paper, the effect was different from silver or plated copper, although treated in a similar manner. Silver plated on copper, gives the true effect of light and shade — while silver on paper gives the opposite — namely, the light parts of the subject are dull, and the dark shades are, in a proportionate degree, light. In order to convince you of the fact, I send you a specimen; but our days of late having been cloudy, you cannot expect it to be as perfect as I would wish. I hope before your next publication to be able to submit to you a specimen on silver plated on copper, and silver on paper, in order that you may more completely understand the difference. Hoping that this communication may have the effect of promoting inquiry on the subject, I remain, your obedient servant, Francis S. Beatty.' "

Hoping that you will have room in your next for this and the republication of the letter — I am, yours, &c.

Dublin, Dec. 11, 1858. FRANCIS S. BEATTY.

UNCORRECTED LENSES FOR PHOTOGRAPHIC PURPOSES.

To the Editor.

Sir — In page 186 of your *Journal*, you state, that if a lens is not achromatic it is useless for photography. I beg respectfully to deny this. The best picture I ever produced was taken with a common meniscus lens; and after repeated trials I marked the tube as I would a spy-glass, so that I never had again to take the focus for a landscape, only put the lens on the marked line. The camera was always the same length, having no slide, and each distance was thus a constant quantity, near object, middle distance, and distance.

And if now about to buy a landscape lens, I should purchase a meniscus, three feet focus (the last I had was sixteen inches), as the distances are usually too great for short lenses, and the light lost in focal length is made up in a great measure by the increased size of the aperture which can be used; and the remarks about chromatic aberration may be met, by stating it is also constant, and a lens of this sort and a tin camera would cost but a trifle in England; the back being sloped, would rectify, in a great measure, errors in near objects.

The size that a lens of this sort would cover would be about eighteen inches, and the pictures are therefore more like works of ornamental art.

I am, yours, &c.

Geelong, Victoria, Oct. 18, 1858. A. K. SPARKES.

[It is evident from the preceding remarks of our correspondent that he is not well acquainted with optical matters, or he would be aware, that unless an object be *beyond* a certain considerable distance from the lens, it is *impossible* that the posterior focus can be a constant quantity; moreover, in an uncorrected lens the amount of allowance for variation of chemical focus will differ with every distance from the object, within certain limits.

The fact of the best picture ever taken by the writer having been produced by means of an uncorrected lens proves nothing, even if we suppose the picture to have been really a good one (as probably it was), because for *very distant* objects a certain point may be found, at which the allowance will remain tolerably constant, provided also that there be no variation *in the density of the atmosphere;* but with near objects this is very far from being the case.

In Victoria, subjects for landscape photography may usually be *distant:* in England, our difficulty is generally to attain a sufficiently distant point of view to include the whole subject.

It is an agreeable reflection, that the ties produced by the pursuit of our pleasant craft, should have drawn forth a letter even from the Antipodes upon mere matter of detail; and although we still maintain the same opinion as we formerly expressed — that an uncorrected lens is not *adapted* for photography — we have much pleasure in communicating with our distant fellow workers. — Ed.

ANSWERS TO CORRESPONDENTS.

P. Thomas — Send a specimen.

Amicus — We have the subject of photo-lithography under our especial notice at the present moment. It is one of which we have great hopes as regards utility.

Conservator — The best portfolio for drawings or photographs with which we are acquainted, is that patented by Mr. Harvey, of Rathbone Place, described at page 247 of our last volume.

J. S.— We shall be happy to answer any *photographic* query, but the other information would not be properly included in a photographic journal.

Thomas Davidson.—We did not receive your communication in time to prepare the Diagrams for this number, but intend to avail ourselves of it for our next.

*** Several articles in type are unavoidably left over till our next, among which is the conclusion of the paper on *Suggestions for the Improvement of Landscape Photography*, &c., by the Editor.

G———. In asking us for the radii of curvature of the various surfaces of the flint and crown glass lenses of the orthoscopic combination, together with a simple means of ascertaining the refractive and dispersive powers of various kinds of glass, it is evident that your acquaintance with the science of optics must be merely *nominal*, otherwise you would be aware that it would require many numbers such as the present to do what you require, even if we possessed the exact knowledge and will to impart it. The various curves, of course, must depend upon the properties of the particular samples of glass employed, together with certain data which Professor Petzval has *not made public*. — To ascertain the refractive and dispersive powers of glass, it is necessary to construct a prism of the glass to be tested, though the latter quality is ascertainable with sufficient accuracy for practical purposes by the finding specific gravity.

THE PHOTOGRAPHIC JOURNAL.

No. 86, Vol. VI.—JANUARY 15, 1859.

We scarcely know whether we ought to regard it as an affront or a compliment that the *Journal of the Photographic Society* made its appearance upon the occasion of the last issue with a similar prefix to its title to that borne by our publication; but as we were clearly the first in the field to announce the intention of adopting the designation of "The Photographic Journal," we presume that we must look upon it in a complimentary light. One thing, however, appears very clear, that the alarm recently expressed relative to the probability of the public being misled by our change of title, into the belief that in supporting us it would be supporting the *Journal of the Photographic Society* must have *altogether subsided*, otherwise the conductors of that excellent publication would scarcely have ventured upon a step *calculated to increase* such confusion, did any exist.

With regard to the change on our part, we have been much gratified with the numerous letters expressive of satisfaction thereon received by us; we have, however, *one* solitary instance to the contrary, so in this, as in other things, the rule is not without an exception.

Perhaps the most interesting event that has occurred in the photographic world since our last, is the opening of the Exhibition of the Photographic Society at the Suffolk Street Gallery, which was honoured, on the 6th instant, by a visit from the Prince Consort. We have no doubt that it will be a matter of considerable gratification to every exhibitor, to learn that H. R. H. very minutely inspected the whole of the collection, and evidently regards the productions of photographers with an eye of affection. Scarcely a single picture amongst the whole was passed without at least transient notice, and the more meritorious works were carefully examined. We question whether there are many private gentlemen, photographers though they may be, who take as much trouble to be certain that nothing of importance escapes examination, as this illustrious visitor underwent on the occasion specified.

Another source of satisfaction to the exhibitors may be found in the fact, that besides having a strong bias in favour of the photographic art, its results are clearly understood and appreciated by H. R. H., not merely in a general way, but with an intimate knowledge of the various minute details of nearly all the processes employed in their production, and this to such an extent, that we found we could almost certainly predict where a longer pause than usual would occur as he approached the neighbourhood of any work, either particularly excellent or possessing any unusual peculiarity. We may remark *en passant*, that the present exhibition is in our judgment a very fine one, and that the labours of the hanging committee have been crowned with a success never before attained at any previous one, not even excepting that of last year at the South Kensington Museum.

As will be seen by our report of the last meeting of the Photographic Society (London), Mr. Pouncey has now made a clean breast of it, and explained the details and *modus operandi* of his process. Although we cannot perceive therein any thing whatever to warrant the proposed intention of securing by patent the exclusive use thereof—seeing that all the essentials have been already included in several other patents, in M. Poitevin's in particular, not vaguely, as has been asserted, but absolutely—still we are of opinion, that something more than the thanks of photographers are due to Mr. Pouncey, for opening up what may in time prove to be a very valuable field of research in the effective application of carbon to the purpose of printing photographs upon paper.

We were certainly surprised to see the great advance that had been made, in the space of only one month, in the improvement of the specimens submitted to the meeting; for although in our 15th December number we pointed out a direction in which we thought operations might be carried on with a reasonable expectation of some success, we certainly did not anticipate so great an amount of it in so short a period as that which we witnessed last week.

Some of the best of these pictures (of which by the way specimens will be found in the exhibition) were from a negative of Dr. Diamond's, containing several small figures accessory to the principal subject, which is an architectural one, being a portion of some ruined abbey, and well suited to display the favourable points of the process. For subjects such as this, very pleasing and satisfactory results can be obtained; but in order that we may not mislead others in this matter, as a contemporary has thought fit to do, we assert emphatically, that even now the proofs are *not* equal in beauty to silver prints from the same negative. This statement ought not to be any discouragement to Mr. Pouncey: he has done much, so much that he can afford to wait with patience while the rest that has to be accomplished, in order to bring up his process to a level with the silver process, shall be worked out, either by his own exertions, or by the willing aid of many that will have been by this time enlisted in the cause.

That we may not be thought to bring a vague accusation of deficiency, we may remark that the points still wanting are precisely those which we have before noticed, but now in a less degree than formerly, viz.—insufficiency of half-tone, and partial absence of atmospheric effects. We need not however pursue the subject further here, as those who feel interested therein will doubtless read the report of the discussion which occurred at the meeting on the 4th instant.

It is a matter of no little surprise to us that there still appears to exist in the minds of some photographers a confusion of ideas relative to the subject of carbon printing, photographic engraving, and photolithography,—all of them important in their special provinces.

In our last we made some allusion to these subjects, more especially with regard to the latter. Since then we have given a good deal of attention to the question of how it may be possible to call in the aid of any or all of these processes, by way of *economy*, in correctly illustrating certain works; and we confess, that to our thinking, the plan proposed by Herr Pretsch, as described in the present number, appears worth a trial. The odium under which Herr Pretsch's process has hitherto struggled, has arisen chiefly we believe in consequence of his

claiming, or having been thought to claim, for it more than its just due: he now admits, and probably did before, that his plates do generally require some assistance from the engraver. So long as that is admitted we see no harm in it; the fraud of its concealment only would be offensive; and though we may fairly wish to do without the engraver at all, there is no sound reason why, if we cannot entirely dispense with his services, we should not, if we can do so, perform nine-tenths of his labour by photography. It must be borne clearly in mind, then, that the object in view is not competition with photographic printing, but an attempt to employ photography in aid of engraving, and thus combine the accuracy of the one with the advantages of the other.

Herr Pretsch meets the objection, that the plates produced by his process, in consequence of their delicate nature, can only yield a comparatively small number of impressions, by suggesting that each of those impressions, by transfer to a lithographer's stone, can be multiplied a thousand fold; and though perhaps some of the more delicate parts may thereby suffer some deterioration, there is no difficulty in rendering them nearly, if not quite, equal to the original by a few touches on the stone itself,—a comparatively inexpensive operation,—thus producing a large number of useful and valuable plates at a very small cost.

We confess that this argument appears to us so feasible that we purpose making an endeavour to put it in practice, and if successful, *present our readers with a specimen of the result with our next number on the 1st of February.*

With regard to photolithography proper, we desire to direct notice to some remarks made by Mr. Hannaford on the subject at the last meeting of the North London Photographic Association, in which that gentleman stated, that from experiments in which he had been engaged, he felt convinced, that the most promising direction in which photographers might direct their operations on stone, would be by first coating the stone with some greasy substance *before* application of the sensitive coating, then by removing the unhardened gelatinous or other organic matter, and the grease covered by it, with the assistance of benzole, ether, or other solvent of fatty matters, and subsequently the hardened gelatine, which, as Mr. Malone observed at the London Society's meeting, is only comparatively insoluble, and thus the desired image would be formed by a greasy substance in the stone, which will be in a condition to receive the corrections and additions of an ordinary lithographic artist, a condition in which few of the stones are left by the photolithographic processes at present in use.

Mr. Pouncey also pointed out that where a negative is employed direct upon the stone, the ink adheres not to the stone itself, but to the hardened organic matter associated with the sesquioxide of chromium upon it, and is thus liable to be readily flaked off in the process of printing therefrom.

We hope to enlist a considerable number of experimentalists in this very useful application of photographic art to practical purposes.

"PHOTOGALVANOGRAPHY," AND ITS ECONOMICAL APPLICATION TO BOOK AND OTHER ILLUSTRATIONS.

By Herr Paul Pretsch.

I will not trouble you here with a long description of my process, it has been explained in several papers. A glass plate, coated with a gelatinous substance, mixed with photogenic chemicals, is exposed in an ordinary copying-frame, with the original in contact, to the influence of light. The original may be a positive photograph on paper, made a little more transparent by some Canada balsam, or a drawing or print; but at all events, it must be transparent enough to allow the light to act through it on the coated glass plate. Very good results are obtained from originals on glass, but they must be transmitted *positive* pictures, not glass *negatives.*

The time of exposure is extremely varying, according to the transparency of the original and to the intensity of the light. After sufficient exposure, proved by practical experience, the plate is taken from the copying-frame, the original remaining unspoiled; and it shows a faint negative copy of the picture, made up of lights and shadows, on the smooth surface of the sensitive coating. The plate is now placed into a bath, and the picture appears almost instantly, as if by magic, transformed into a raised surface, in which the elevation and granulation of the different portions are in exact proportion to the intensity of the shades in the original picture. It seems as if the effect of light on the film were at once to darken and to harden it, so that those portions which have been fully exposed to the actinic rays—namely, the lights of the original—are almost impervious to the liquid of the bath; while in the dark shades of the original, this effect has been scarcely felt, and the liquid entering freely, *swells* the gelatinous compound, and causes its surface to rise.

All the tints of the photographic original are reproduced by a brilliant and wonderful granulation. This granulation is a peculiarity of my process, and it is indispensable for the reproduction of any tint by a printing plate. We can only print from a plate in lines, where the picture is represented in more or less fine and close granulation. It is not sufficient for an intaglio printing plate to represent the picture in sunk portions; but these sunk portions must consist either of sharp lines or granulations, for the purpose of retaining the printers ink. This required granulation is formed by my process itself, but a contemporary of mine is compelled to produce it by applying on the coating of the plate the dust of a resinous substance, well known to engravers, under the name of aquatint grains.

If however the original consists of lines—as, for instance, in a pen-and-ink drawing, or in an impression from an etching—the copy appears also in lines, perfectly corresponding to the effect of the original.

The beautiful granulation is perfectly capable of reproducing the tints of the original, if they are in existence, and decided enough to be recognised; but from a vague undecided original I certainly cannot produce a brilliant engraving.

Having obtained the coated glass plate with the raised picture on it, produced by the process just described, there is nothing more wanted than the transformation of such a plate into solid metal to print from. And this transformation *has* been executed, by taking a mould in gutta percha from the picture on the coated glass plate; and a faithful mould too, showing all the delicate portions of the first plate as well as the stronger ones. But this mixture of gutta percha, with some greasy substance, is not the only one that may be used. According to circumstances, mixtures of wax, pitch, stearine, resinous substances, &c., can be successfully applied.

The picture on the glass plate being raised in the mould, consequently appears sunk or intaglio; so that were the *material* suitable, the mould would be fit to print from. In order to obtain the ultimate printing plate in copper, a double electrotype process is necessary—a process which although not very new, is nevertheless one of the wonderful inventions of our own time.

The surface of the mould is prepared and rendered conductive of electricity, by plumbago, by bronze powder, or by a film of silver; and in such a state, surrounded by a wire or band of metal, the mould is fit to be placed in the electrotype apparatus for the purpose of obtaining by deposit a firm sheet of metal upon it. The reverse of the mould, therefore, like the picture on the glass plate, is raised. This is called the matrix, because it serves for the purpose of making the intaglio printing plate from it, by repeating the same process of electrotyping.

Any person conversant with the electrotyping process, will be perfectly aware how certain we are by these means to obtain a true and faithful copy of the original. As an instance, permit me to mention, that if we touch the mould or the bright surface of the matrix with the finger, and obtain by doing so an impression of our skin on the polished surface, such an impression is faithfully reproduced by the electrotyped copy. Therefore, we ought not to be afraid of the complication of the process, because the same process of moulding and repeated electrotyping is applied in the nature-printing process, in multiplying engraved plates of maps, and of bank-notes, under circumstances where the utmost accuracy is indispensable.

The process has the advantage of consisting of several distinct operations, which are independent of one another, and most of which may be performed at any intervals of time that may be convenient. The original photograph need not to be used for months after it is taken; the coated glass plates, even with the picture on them, may be preserved with care for a great length of time. The mould will keep almost for ever, and the copper matrix will yield any number of precisely similar plates. The gelatine and the chemicals are comparatively inexpensive, and the glass plates may be used over and over again, any number of times. The most

costly part of the process is, therefore, the electrotyping, the expense of which varies according to the thickness of the plate required — from 1½d. to 4d. per square inch.

Objections Refuted.

Two objections have been brought forward. The first, that many of my plates require to be touched by the engraver; and this has been regarded almost as a *crime* of mine, done secretly and concealed. Now it appears ridiculous to attribute to me a crime that is done constantly by photographers who take portraits, which are generally touched up. Moreover, I know one of the first copperplate printers in London, who is constantly engaged in mounting photographs, because he possesses such a peculiar and very nice *sort of glue*, which answers so very well for the purpose, that I have seen some photographic landscapes which had shown, *unmounted*, many faults, which, however, have been imperceptible after having been mounted with this *very admirable glue.*

I readily admit that many of my plates have been really touched by the engraver — in many cases more than was necessary, more than was wished for. But as a small proof of my sincerity, I have deposited, out of sincere respect to this country, and as a record of what was really executed here a few years ago, a series of impressions from *untouched* plates, in the print-room of the British Museum. The successful application of my invention will be bounded by the same limits as those which circumscribe the power of photography itself. A subject which is not well adapted for photography cannot give a good photogalvanographic picture. You are at fault in the first stage of the process, and the subsequent operations will do nothing but repeat the original imperfections. I cannot reproduce an engraved plate, as required by the taste of the public, from an original which is wanting in definition. There are many photographs with a veil over certain portions of their details; the public is content with them, because they are covered by the fascinating rich tint of photography, and because they allow to the imagination of the spectator free play for his ideas. But the public is not satisfied with this undecided definition in an engraving; they will *see*, and *know*, and *understand*, what there is represented. Therefore only perfect originals, with clear definitions, ought to be used in my process.

In many instances, the capability of being able to touch up is of great advantage. Who would not like to remove a stain from an otherwise brilliant picture? Before rejecting the picture altogether, he will certainly at first try to remove the stain. Why shall we not give a tint to the sky, which is generally white in a photograph? Some of the plates do not require a single touch, though many have to be cleaned and rubbed down before they are in a fit state to print from, and some are very much improved by touching up here and there. But the greater part of the work is done when the plate comes out of the electrotype apparatus; and a plate which would take the engraver twelvemonths of unremitting labour to execute, can be turned out by my process, allowing ample time for any touching up that may be wanted, in a few weeks, with trifling expense, and particularly so in comparison with handwork. Thus, the mere saving of highly skilled labour is immense, and what is of more consequence, the touch of nature's own finger is preserved, and an accuracy is attained, to which any mere mechanical skill must of necessity be inadequate. I can and will not compete with the brilliancy of the engraver's tricks in steel engraving; but I can compete, in every respect, in truth and faithfulness. The main point is, to apply as little touching as possible, and if indispensable, to apply the same JUDICIOUSLY.

The *second objection* which has been brought forward against my process is, "That my plates do not allow a sufficient number of impressions to be taken from them." But I will show that this also is unfounded.

1st. At present almost all engraved plates are executed on steel, consequently the printer is more experienced in handling them than copperplates. The process of "wiping" ought to be done in such a way, that it is not like "grinding" the plates. Even in keeping engraved copperplates, attention ought to be paid to protecting them against the injurious influence of oxidation by the air. By neglecting this, we may spoil the plate to some extent, and lose fifty good impressions at once; and by the want of the required attention in the wiping, we may lose some one hundred more. I have met with some instances where I have obtained from similar plates several hundred impressions more by one printer than by another.

2nd. Everybody conversant with the process of electrotyping, knows perfectly well that we are able to produce, at will, hard, or soft, or brittle copper, according to circumstances.

3rd. It is well known to some, that there is in existence a process for hardening electrotyped plates, which is in constant use at the Ordnance Map Office in Southampton, and that plates so hardened produce at least some thousand impressions.

4th. A new process exists now for covering copper plates with a very thin film of iron, thus making them capable of yielding almost as many impressions as steel plates. I myself do not yet possess any experience in this process, but I have no doubt that it is a considerable improvement for engraved copperplates.

5th. A very practical advantage can be obtained by making from the copperplates transfers on stone. By this mode we keep the copperplate always in a good state, and print only from the stone.

A great number of impressions can be obtained in this way; and although the impressions from the stone are perhaps a little less perfect than would be from the original copperplate, nevertheless this method will answer perfectly in many cases.

ON DRY COLLODION PROCESSES.

By Dr. Hill Norris.

A thorough comprehension of the fundamental principles of dry processes is the only guarantee of a fair proportion of success in this branch of photography. It is not sufficient to possess recipes and formulæ; for photography, like physic, cannot boast of specifics. The remarkable list of substances which stretched ingenuity has suggested to preserve the capillary condition of the collodion film is a witness to the fact, and evinces the almost total want of fixed principles to guide the photographer in a proper selection. We must hope that this empiricism, so fatal to true progress, will ere long give place to a more philosophic spirit.

It is proposed to-night to discuss the subject of dry collodion under four separate heads, viz. — Adhesion of the film, sensibility to actinic influence, retention of the invisible image, and developement, as under these four divisions the entire phenomena of dry collodion may be treated.

First, then, adhesion of the film.—Non-adhesion may occur in two ways, viz.—by blistering and by stripping or washing up. The former is peculiar to preservative substances, the latter to collodion, without any superincumbent adhesive substance. The blistering results from the preservative substance expanding when wetted. The stripping up, or washing off, is the normal condition of a simply washed and dried film of collodion; to steer between these two conditions is therefore clearly our course, avoiding the blistering on the one hand and the fragility of film on the other. Fortunately this is easily accomplished, as collodion will bear a sufficient amount of expansion, and at the same time a very small amount of gelatine or albumen will confer stability on the film.

Applying these principles, if a given collodion rises in blisters, with the application of a four grain solution of gelatine, all we have to do is to reduce the strength to two grains, or even less, as one grain is amply sufficient for conferring stability on the film during the various subsequent aqueous operations. It must be understood, that all these remarks refer to dry processes properly so called, as from this category all such are excluded as contain substances having marked hygroscopic properties, or in a word, all such as will not bear moderate friction with the hand when dry. It has been said that the coagulation of albumen in the film prevents blistering; but this appears to be an error, for if any strength of albumen be left on the plate, blistering will undoubtedly occur. Meta-gelatine has also been advocated on the ground that it might be applied cold; but my experience contra-indicates the application of cold solution as likely to give 50 per cent. of stained plates by an incomplete removal of the nitrate of silver, which being dried in the film is reduced by the pyrogallic acid. Meta-gelatine, in the hands of amateurs, probably gives greater freedom from blistering, owing to its fluidity and a smaller quantity being left on the plate; but this is counterbalanced by the tenderness of the film, *i. e.*, its liability to strip.—We now pass on to consider the sensibility of the dry film to actinic influence. The greatest degree of sensitiveness with which at present we are acquainted exists in the most exalted conditions of the wet collodion film; and as that film is saturated with free nitrate of silver, photographers have generally imagined this to be the direct cause of sensitiveness, and that its partial or complete conservation in the film would confer the much-to-be-desired end, forgetting that the state of the nitrate in a dry is totally different to that in a damp process. By the use of organic substances, it is quite possible to retain the whole of the nitrate in the film without decomposition; but it no longer exhibits its peculiar influence as in wet processes, nor is it correct that the existence of an organic salt of silver (as the albuminate) confers

any sensibility. The fact is, neither nitrate of silver or any organic salts of this metal have any direct action in the sensitiveness, but the former acts in an indirect manner, by preserving the *integrity* or "*intact condition*" of the compound on which sensitiveness depends.

The maximum sensitiveness of a dry plate from any given collodion, is obtained by simply washing such plate from the nitrate bath with distilled water and drying. No preservative application capable of complete dessication at present known, no matter how applied, has the slightest accelerating effect; but, on the contrary, many substances so employed have a distinct *deteriorating* tendency. Gelatine and albumen are in this respect perfectly neutral, but the latter so only when its affinity for metallic salts has been satisfied, as under other circumstances it tends to the destruction of the sensitive compound, ultimately reducing the plate to complete insensibility. Looking upon moderately sensitive collodion as uniting plates without any preservation, or preserved with gelatine or albumen, will be represented by six, or in other words, will require six times the exposure. It was not my intention here to enter into the chemical nature of the sensitive compound, as this, with the nature of the invisible image, will be found fully discussed in a paper preparing for the Royal Society of Edinburgh; but as the subject has been alluded to, I will call your attention for a moment to the composition of the iodide used in photography. On precipitating iodide of silver by double decomposition, taking care to retain an excess of silver salt, we have a decidedly yellow precipitate, and on repeating the experiment with the alkaline iodide in excess, we have a white salt. On the very outset of our inquiries we observed their physical difference, and numerous subsequent experiments have led me to infer, that instead of there being only one compound of iodide of silver in use in photography, there are no less than four. The composition of which may be thus expressed—

$Ag.\ I + Ag.\ O, NO_5$	The collodion albumen of paper compound.
Ag, I	The daguerreotype compound.
$Ag, I + K I$	The insensitive iodide of chemists.
$Ag. I^2$	The precipitate with free iodide in excess, also insensitive.

Or in other words, the most sensitive compound of iodide of silver consists of one equivalent of iodide of silver, plus one equivalent of nitrate of silver. This salt, in an amorphous condition, but not so sensitive, may be crystallized, as shown by Schauss, and is still sensitive as in its amorphous state. It is immediately destroyed on contact with free iodine or alkaline iodide, and is depreciated by water, but not absolutely decomposed, at least so long as the smallest proportion of free nitrate of silver exists in it. Indeed, iodide of silver and nitrate of silver cannot exist together without determining its formation. Alcohol does not decompose it; hence, if the free nitrate of silver were soluble in this menstruum, and could thus be removed and a preservative substance applied, itself having no tendency to decompose this compound, we might make a dry plate as sensitive as wet. The daguerreotype compound comes next in order of sensitiveness, but is far inferior in this respect to the former compound, the ratio being about one to thirty. By a peculiar combination with bromine, its sensibility is well known to be exalted, but even then it does not reach the sensitiveness of the former compound. The remaining salts are both nearly, but not absolutely, insensitive to light, but so much so as to render them useless in photography. Some explanation may here be necessary as to the various degrees of sensitiveness found in collodion albumen and paper processes, but as we have seen that mere washing interferes with the integrity of the compound, it may be readily conceived how certain substances, by introducing special affinities, diminish the sensibility; and this is borne out by the fact, that where the conditions are the most perfect for preserving this compound, we have the greatest sensitiveness, owing to the presence of excess of alcohol, æther, and nitrate of silver.

Retention of the Invisible Image — Dry collodion plates possess the singular property of returning perfectly to their former sensitive condition, after having been exposed, if kept for a sufficient length of time in the dark. Extraneous conditions influence, to a great degree, the rapidity with which this occurs, requiring as it does sometimes months, and at other times weeks only. Damp or moisture assists materially this action; and therefore damp processes must be expected to fail in this particular. The thickness also of the preserving pellicle modifies the result; for if thin, this phenomenon occurs more rapidly, probably on account of the readier access of moisture, the presence of which appears to assist in the reversion of the chemical changes induced by light. This will at once indicate the impropriety of setting aside preservative substances, even if collodion could be made to develope well without them. Minute proportions of the vapours of iodine, bromine, acetic, nitric, and sulphuric acids, also destroy the image; but as some of these remove also the sensitiveness of the plate, their action is not analogous to the spontaneous return of the exposed compound to its normal condition, and is referred to here as a caution against keeping exposed plates amidst the emanations arising from a well-stocked laboratory.

Developement—In developement as in sensitiveness, the wet plate is our model; and certainly the best test of a really good dry process, is the ease, rapidity, and cleanliness with which it developes with pyrogallic acid. Inferior processes may yield tolerable, or even good, results by the slower method of developement *with gallo-nitrate*. It may be stated as a rule, that no plate should occupy more than five minutes in its complete developement, and should not require the developer to be renewed more than once. The greatest objection to the use of albumen, as a preservative substance, is the fact, that when coagulated, it resists the permeation of liquids and prolongs materially the developement. This does not apply with equal force against collodio-albumen, as the particles of coagulated albumen have not that continuity, or do not form a skin over the iodide.

It has been shown in former papers, that brilliancy and intensity depend almost entirely on the porosity of the film, and that this condition was common to collodion long iodised.

It has been recently suggested to bring about this condition by means of ammonia, and if from five to ten minims of strong liquid ammonia be added to twenty ounces of plain collodion, in about a week the pyroxyline undergoes a change, technically known as craping, the film being visibly opened — if now a small proportion of new collodion be added, just sufficient to remove the openness, we have a product suitable for dry work. The collodion so treated should contain more than the usual quantity of pyroxyline, and should be iodised freely as the action of the ammonia renders the collodion thin and fluid.

In conclusion, I must allude to the importance of temperature in developement, as cold entirely suspends this action; therefore in cold weather it is necessary to pay special attention to this particular, and if the chemicals are below 60°, to warm them artificially, and also the water with which the plate is wetted.

ON A FORM OF MAGIC LANTERN ADAPTED FOR EXHIBITING PHOTOGRAPHIC TRANSPARENCIES.

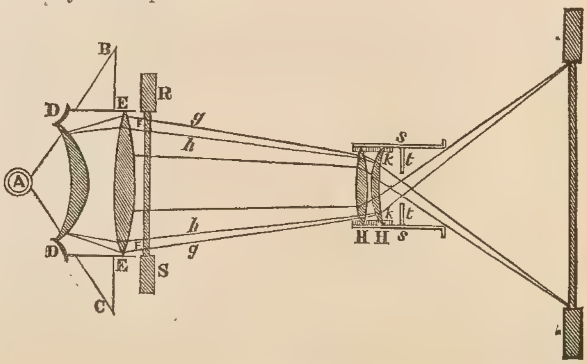
By Thomas Davidson.

Perceiving that considerable interest has of late been shown in the adaptation of photographic transparencies to the illustration of lectures, by aid of the magic lantern, the following hints relative to the best arrangement of lenses, to ensure good definition and flatness of field, may possibly be acceptable.

I may premise, that my long experience as a working optician enables me to speak from a practical acquaintance with this particular subject, to which I have devoted much attention.

The following arrangements will be found adapted for the oxyhydrogen, oxycalcium, Bude, argand oil, or indeed any of the usual sources of illumination:—

For many years a noted London firm adopted a principle that was a great improvement on the old school, but retained some serious errors in their illumination, which I will point out and then show my own improvements.



Let A represent the burner or lime light, D D a deep meniscus, and E E condensers, either in oxyhydrogen, lanterns, or micro-

scope; now the rays A D B, A D C would form the great angle A B C, but falling incident on the deep meniscus at D D, will be bent or refracted to the edge of the second condenser E E, and so on to the object glasses—the red light in the direction g k, g k, and the violet in the direction hk, hk. I should observe, that the ray A D, A D will be separated as shown by the refraction of the deep meniscus, but the red light will fall nearest the edge of the lens E E, where its refraction is strongest, and thus make up for the lesser refrangability of the red light. H H is the compound object glass, consisting of a crossed convex and a meniscus lens, recommended by Sir John Herschel as being freest from spherical aberration; S S a brass tube, carrying the object glasses and the stop t t.

The merit I claim on this principle of condensers is the great intensity of light obtained; the distance between the condensers should be equal to the difference of their focal lengths, as in the Ramsden's positive eye-piece, which is nearly free from aberration, and gives a flatter and larger field than others. I should also observe that the curvatures of the deep meniscus particularly, as shown in the diagram, is not so deep as it might be.

Next, as regards achromatic object glasses for lanterns, I have fixed on a formula which I am working, and will let you know the result.

My aim, however, is to show the superiority of the principle; and although it is good, yet with such deep curvatures it cannot be expected to be *perfectly* free from spherical and chromatic aberrations—it is only as near an approximation as we can arrive at. The light must be moveable, so as to slide backwards or forwards, until the disc is seen finely and regularly illuminated.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

THE ordinary general meeting of this Society was held on January 4th, 1859, ROGER FENTON, Esq., in the chair.

Mr. POUNCEY read a paper descriptive of his carbon printing process:—He uses, first, a solution of gum-arabic about the consistence of oil; secondly, a saturated solution of bichromate of potash; and thirdly, some of the finest carbon (such as is employed by makers of printing ink), ground very perfectly with water. Plate paper, well cylindered, is covered by a mixture of equal parts of the two former solutions, with about one-eighth of the ground carbon added. It is to be laid on by means of a large camel's hair brush, and allowed to remain on soaking for two or three minutes; the superfluous material is then removed by means of a brush, known as a four-inch hog hair softener, using it so as to leave a smooth surface. When dry it is fit for exposure under the negative, after which it is put to soak, face downwards, in water for about six hours.

A variation in the proportions of the materials is required to suit the various negatives used, as well as regulation of exposure. If the black parts come off in flakes, more bichromate should be used; if the whites are not clean, more gum; if the shadows are too grey, more carbon. Of course the converse of these propositions also holds good; and it is scarcely necessary to intimate to photographers, that the paper must be prepared in chemical darkness. There were sundry remarks upon "a change having come o'er the spirit of Mr. Shadbolt's dream," and others upon Mr. Malone's observations at the previous meeting about photolithography.

Dr. DIAMOND — The Rev. Dr. Holden was here to-day, and is unable to attend this meeting, but wished this letter to be read this evening.

The letter was read, and pointed out the deficiency of gradation of tone and atmosphere as compared with silver prints, and stated that another impediment to the use of the process amongst amateurs, consisted in the absence of any visible impression after exposure in the pressure-frame, thus rendering it extremely difficult to ascertain when the proofs are sufficiently acted upon.

The SECRETARY, after reading the letter, said — I may make one observation in respect to it, that having seen Mr. Pouncey operate, I could perceive, even on a very dull day, effects produced by the operation of the light which Dr. Holden does not appear to have observed.

Mr. POUNCEY — May I be allowed to say one word with respect to half tones. These pictures are all printed from a negative which Dr. Diamond has kindly lent me, and it cannot be said that there is too great a contrast there between lights and shadows.

A MEMBER — May I ask Mr. Pouncey if the remarks of Dr. Holden can be satisfactorily answered—that is, whether there is sufficient evidence on the face of the picture of the proper length of exposure in the pressure-frame?

Mr. POUNCEY — I think Dr. Diamond partly answered that question, when that gentleman said he saw me operate on a very dull day. I could not positively assert that you could *always* see it; but I can assert that you can invariably, if exposed to the sun. Suppose it had been exposed three hours to-day and found sufficient on going into the water, I should not be able to observe it; but having printed from that negative, I can tell how long another proof from it requires.

Mr. MALONE — Mr. Chairman, I believe that I was the occasion of bringing on this discussion; and many remarks have been made to-night by Mr. Pouncey, which perhaps I may be permitted, very briefly, not to meet *seriatim*, but to dispose of generally, and I trust satisfactorily.

Mr. Pouncey deprecates the having mixed up the two subjects of photographic engraving and the carbon printing. Now, I would ask Mr. Pouncey to learn that the occasion of the subject being introduced here, was the exhibition of specimens of Mr. Fox Talbot's works. I brought specimens of Fizeau's process of engraving and of photolithography by Monsieur Poitevin, with a view of comparing them with Mr. Talbot's engravings. Having thus elicited an interesting discussion, it was thought desirable that it should be adjourned, and that we should import into the subject the question of carbon printing, so that it is Mr. Pouncey who is out of order. That is the truth with regard to the origin of this discussion.

Mr. Pouncey does not seem to be satisfied with the manner in which I explained the photolithographic process. His remarks arise partly from misapprehension. Monsieur Poitevin kept secret his method of manipulation; and I do not think that my remarks deserve to be met as they have been by Mr. Pouncey to-night. I observed that we do not know the *exact chemical action* in any of the processes. These are proper remarks to make, and ought to be met in a fair spirit. With regard to the insolubility of the substance, it is a question of comparative insolubility. I stated before, that we *can* dissolve off *all* the bitumen, and so we can the carbon. Mr. Talbot, by water, removed certain parts of the gelatine which were not acted upon by the light. I made the remark that it was a consideration whether we put the positive upon the stone or the negative. I was then told we could not put a negative on the stone without reversing the plate. Mr. Pouncey is probably unaware, that by using a prism in the camera we can obtain a reversed negative (adapted for use) directly in contact; therefore that is only a question of convenience and time.

I have no desire to act the part of an opponent of Mr. Pouncey in any way. I looked at his pictures very carefully, and it appeared to me that the carbon print did not exhibit the phases of half-tone and atmosphere equal to the silver print. I at once said so. I was then shown other prints—two in particular—one of a purplish black and the other of a warmer colour. Upon looking at them, I thought that which I did not like to utter; I thought they were both very indifferent photographs, and that an attempt was being made to discover what skill I had. Mr. Pouncey took advantage of my hesitation, and said I did not know the one from the other. Now, it is a disadvantage to us that the report of what I said was not revised; for I find it was stated that I said that they were both photographs that were shown. If I can be disabused of the belief that I cannot distinguish one from the other, that will settle the point in Mr. Pouncey's favour, and I will make the acknowledgment, for I have no opposition to carry out and no end to serve. Now, the whole controversy lies in a nutshell — it is the printing upon silver, upon any paper we please, *versus* printing by carbon or some other agent. Suppose for a moment that I cannot distinguish a good silver print, such as of a statue or a portrait—for I will not agree that a print of a building is a fair criterion; short of that, I will never be satisfied to give up the present mode of printing for the carbon printing, much as I desire to see the latter in full use. I find Mr. Pouncey is still labouring under the fallacy, that because of the earlier photographs, 80 per cent. have been stated to have failed, they must *inherently* fail; but do the present photographs fail? If they do not *necessarily* fade, I say, for present purposes, they are as good as carbon.

I will show to any gentleman a photograph printed in 1844, which looks as fresh and free from signs of fading as any of the present time. As long as that remains authenticatedly unfaded, we must acknowledge that silver prints do not necessarily fade. But I am met with the statement, that 80 per cent. have gone. Well, in 1844, we none of us knew the exact amount of washing

required. I know now that there must have been a trace of hyposulphite of soda left in every picture of that period, and yet in spite of that trace many of these pictures remain, and if so, what may we not expect with our present skill and knowledge of the past? Supposing for a moment that the carbon prints are equal to silver prints, then, is the carbon process or the silver process likely to be easier in its application? After washing, must we find out that it is done too much or too little? If that is the case, it is inferior to the present mode of printing; but if the carbon print will give you delicacy enough, then you will doubtless use that process.

Mr. SHADBOLT:—As Mr. Pouncey has made some rather pointed allusions to me, I presume I may be permitted to observe upon them. He says, *that a very considerable change has come over the spirit of the dream* with regard to me. Probably if that be the case, he will remember that when I first undertook to publish the remarks that might occur to me in connection with photography, I stated that I should not be backward in giving an opinion, although I might afterwards have to alter it, because one can only judge by the data before us, and not by those which might be before us in future. I have ever intended to state candidly my impressions at the moment of writing, and it is not because I have thought unfavourably of a process, that I should not, when convinced that I erred in judgment, admit that my prognostications were incorrect. With regard to a certain gentleman who has been mixed up with Mr. Pouncey in this matter of carbon printing, I think that the latter has experienced far more injury by this circumstance than by any thing I could have said, or any one else here have done, in delaying the publication of his process. The gentleman alluded to has claimed for the carbon printing process, (not as it is at present, but months back,) a position *fully equal to silver printing in its artistic effects*. Now although we have laid before us this evening some excellent specimens of the carbon process, I cannot yet allow that they are equal to the silver prints of the same subject; they are good, and, as I admitted the other evening, full of promise, but there is an absence of that atmospheric effect which is, in matters of art, a *sine qua non*. Mr. Pouncey has claimed for his process effects perfectly equal to those by silver printing. He will excuse me in saying, he is under a misapprehension as to what is meant by the expression half-tone; it implies a gradation in every phase from deep shadow to perfect light, and in this *(holding up one of Mr. P's exhibited prints)*, there is no true half-tone; the nearest approach to it is in *that* deep shadow.

Mr. POUNCEY:—I produce that picture as containing no whites.

Mr. SHADBOLT:—What you regard as half-tone is produced by *a slight granulation*. Now in a silver print there is no granulation; it is more like a softened wash of sepia, or of Indian ink. You will perceive that in this silver print there is under the circle a beautiful gradation from deep black to grey. Now a remark which I recently made, and which I should have made to Mr. Pouncey upon our last meeting was, that this carbon printing process offers a very material advantage, provided we can carry out a little more of the manipulating operations, in conquence of its presenting the possibility of using what we call *weak* negatives. My opinion is, that it will be found that negatives of that class are the best for the carbon printing, and they are precisely those which are the worst for silver printing.

I stated at the outset, that I did not think the carbon printing process presented favourable aspects, in consequence of the material employed—the bichromate of potash. In every species of photography which I have seen in which the bichromate of potash has been used, an *exaggeration* of light and shade has been the consequence. Mr. Pouncey has called attention to a statement that 80 per cent. of photographs will fade. I think that that is a remark made in an exceedingly loose manner, I will not say, by an exceedingly loose writer, the Rev. Dr. Holden; in his letter which has been read this evening, I think he expresses opinions in nearly the same words, certainly the same ideas, that I uttered and printed subsequently to the last meeting of this Society, with regard to the want of aërial perspective, or rather, want of atmosphere.

I will now address myself to the remarks of Mr. Malone. He seemed to take objection to a very practical point, which I think Mr. Pouncey has clearly explained, viz.—that if you make use of a negative, and by that means get the image upon the stone, the parts covered by the hardened organic matter are those to receive the ink. But in the process patented by, I believe, Messrs. Cutting and Bradford of Boston, the unaltered bichromate of potash, &c., is removed by means of soap, and consequently those parts of the stone are capable of receiving the ink.

I will now conclude with one or two questions to Mr. Pouncey. First of all, in his description of the mode of proceeding, he did not state the particular kind of paper which he thinks most useful; and secondly, although he mentioned that he removed the superfluous carbon with a brush, he did not name the kind of brush with which he did it?

Mr. POUNCEY:—In reply I may state first of all, with reference to taking a reversed negative, it is "necessity which is the mother of invention." When I wanted to get one, I did not employ a prism, but I coated a piece of glass, and then took another piece of glass, and with some gutta percha I fastened them together, and with small pieces at the angles to preserve contact, and put them into the camera the reverse way, so that I thus took my negatives as I wanted them. Gentlemen must not think that I am not up to all these dodges. I understand Mr. Malone to admit that 80 per cent. of the silver prints fade. May I be allowed to ask how many faded by the side of that one that remained in "the pencil of Nature?" Supposing that there were one or two left, will that prove that silver printing is perfect? I think not. Then I may be allowed to refer here to what was stated by a gentleman, I believe at one of the meetings of this Society: he produced a numbers of prints, and said, Look at these, I believe that the toning of those prints is due to hypo sulphite left in the paper; they have been to almost every climate in Europe, and they are as good now as then, so that here is the greatest puzzle. Can we gather from Mr. Malone's remarks that the hypo sulphite is not the cause of fading? Now with reference to Mr. Shadbolt's questions, I cannot give any definite name for the paper. I should call it a thick drawing paper, which is very absorbent; that [*holding up a print*] is a print which is prepared before pressing, the consequence of which is, that the block has stuck fast; the prints *here* are pressed before the solution is put on, and the whites are clean. The brush is what is called the four-inch hogs-hair softener, not a badger-hair. I worked first with the badger-hair, and had two, one of which was worn, and I found that upon laying that aside and using the other, I did not get such good results. It struck me therefore that a hog's-hair brush would do it better, and I found it so. Is there any other question?

Mr. DELFERIER:—It is not stated what the solution is.

Mr. POUNCEY:—Equal parts of saturated solution of bichromate of potash and a solution of gum-arabic—I cannot give you any definite rule for the proportions. I dissolve one ounce of gum-arabic in three ounces of water; by the time that is half used, some of the water has evaporated, and I have been obliged to again make it thin enough. It is a solution of gum-arabic about the consistency of thin varnish, for if you have it too thick, the picture is more likely to break. The best proportion I know at present is equal parts. The advantage of my process in reproducing scarce engravings is immense Just ask any printseller in London if he has any very old prints, perhaps he will produce one no larger than THIS, and ask you twenty guineas for it, although it perhaps originally only cost a guinea.

Mr. SHADBOLT:—There is one point that to my mind gives more promise of success than almost anything else Mr. Pouncey has mentioned, and that is, that he finds it necessary to use varying proportions of bichromate with gum in order to follow up the varying density of his negatives—that shows it is under control to some extent.

Mr. SEBASTIAN DAVIS:—There seems to me to be a difficulty exactly corresponding with that of the ordinary photograph, I mean entirely to remove the sensitive solution from the paper, because the danger seems to me to be in the lights darkening. I could say that sometime since I was practically engaged in lithography, and I was then convinced that by no possible means could we get a photograph from the stone; for this reason, because there is always the difficulty of filling up the intermediate spaces, and nothing on stone will give the equal gradations of shade presented by the ordinary photographs, and this seems to me to be the insuperable difficulty.

Mr. DELFERIER:—It seems to be a question of whether the carbon can be brought to rival the silver in excellence, and not a question of permanency. We are here to discuss the merits of the carbon process and not the failure of the silver.

Mr. MALONE:—We have a double discussion, for Mr. Hardwich introduced the toning process.

Mr. DWYER:—It is scarcely fair to compare the silver printing of 1844 with silver printing of 1858, because the toning has been quite altered.

Mr. HUGHES:—I am sure every member present must be delighted with the different aspect under which Mr. Pouncey has

appeared to us this evening, and regret the unfortunate state of mind which he presented to us on the last occasion. I know Mr. Pouncey will not think I am personal in making these observations. *He* was not in a happy state of mind for explaining his process, and after a few remarks I doubt whether *we* were in a happy condition to receive his explanation; but he has met us here to-night in a very different spirit, and let us into the secret of his process. I think we ought to look leniently at his endeavours, seeing that his process in so comparatively short a time stands high, and its main merit is that in which our process is the weakest. If, during a few weeks, such a change as we now see can be produced in his prints, we may reasonably hope that it may be advanced still further. But even supposing it could not go further, there doubtless could be found a use for it, and it would fall at once into its proper place. I, for one, cannot see why we should not have several different *printing* processes as we have different other processes. We have the ordinary calotype which is beautiful when portraying rusticity, and we have the ordinary wet collodion and dry collodion processes *ad nauseam*; but hitherto we have had but one printing process, which is marvellous in its first existence—giving us first the red hue which we have got rid of, but with it we have got rid of a good many of our pictures too, for I think the fading of so great a number is solely due to the villainous old hypo-baths. In the daguerreotype we had a very perfect process projected and carried out by Daguerre, but that process just wanted one finishing stroke to arrive at its present excellence, and after arriving at which it never moved beyond. It required the film of gold to be precipitated over it, and those pictures are the most permament which the art has yet shown. This brings me to notice that Mr. Hardwich almost supplies in his process something like Fizeau supplied to the Daguerreotype. We all expected that it was gold upon which we had to depend for permanency, but it was so mixed up with hypo that until it was separated from it we could have no dependence. Now, Mr. Hardwich at our last meeting presented a very interesting process, and I dare say that many of us have since attempted to work it out with different degrees of success. We all like albumen prints, and until lately it has been almost impossible, except with some sulphuretting compounds to get a good colour. I do really think that I am not exaggerating when I say that photography has not stood in so high a position until we had this interesting exposition of Mr. Hardwich's. With respect to the observations of Mr. Malone, I do not think that the silver prints should be so perpetually compared with those in carbon. Let photo-lithography and all its subsidiary branches go on, but it is the plain direct printing on paper which is our object; and although we may import the sister arts into our own, it is quite beside the question. I think we had exhibited at our last meeting important steps towards permanency. If Mr. Pouncey will not push us to pronounce an absolute opinion upon silver *versus* carbon, we shall be in a condition to thank him for his contribution towards photographic improvements, and I have no doubt now that he will find practical photographers will assist him in getting rid of any existing defects.

There is a point alluded to by Mr. Shadbolt, that the negative should be suited to the mode of printing; now it is quite possible that the same kind of negative will not do for different processes, and I can easily imagine a condition in which carbon would give a better print from the negative than the silver. In the daguerreotype we have the positive direct, while in the other photographs we have but two halves; and if they do not fit, we have an imperfect positive. We may have a set of negatives that will print on plain, but not on albuminised paper, and *vice versa*, and it is but reasonable to suppose that in a new method of printing altogether, the negatives should have a character of their own also. I will hint that I see no reason why we should not have ink processes with the same degree of developement as Mr. Pouncey's.

Mr. Wood:—The question resolves itself into two points—the appearance and the permanency. With Mr. Pouncey's permission (when I came into the room) I pointed out all that were silver and all that were carbon; there is, therefore, a difference of half-tone which I think depends entirely on the amount of exposure, no matter what the process may be. The difficulty, as it appears to me, lies not in taking the half-tone but in getting that smoothness by which you pass from one tone to another. In Mr. Pouncey's there seems to be a certain roughness, as though the prints were produced by a sort of combination of little spots. Permanency is a chemical question, and can only be solved by chemical inquiries. It appears to me that all silver prints have something in them by which they will inherently fade,—my theory is, that in all our processes the action of light is not on the metallic compounds but on the organic matter with which those compounds are in contact. The distinction between inorganic and organic is not sufficiently defined; but you will find that, in all cases, the action of light is upon the organic and not upon the inorganic matter. In all silver prints then, in whatever way produced, negatives or positives, I regard the picture to be a compound of organic matter and silver; and so long as these are united there will always be the great danger of light and damp, and other atmospheric influences, combining together to oxidise the organic matter in contact with the silver, and throw it down in a metallic form, until at last we have nothing but the metallic silver in the paper, forming so slight a layer that all the picture is obliterated. This being the case, I think that the substitution of carbon for silver is a very great step in advance. It may be said that in carbon we have an organic substance; but there is no substance in nature so permanent. The sesqui-oxide of chromium, which we must take to remain in the paper, has been subject to severe tests by the Photographic Society of Paris; therefore I think it is our duty to encourage the carbon process.

The cause of failing in silver prints appears to me to lie in the fact that more or less of an acid solution of sulphate of soda has been used instead of the alkaline solution, and, in the second place, in the atmospheric condition. I cannot agree that the daguerreotype is more permanent, because it has not yet been subject to the same severe tests that other photographs have.

Mr. Malone:—Say that we cannot tell what the composition is—that it contains silver, we know—but it contains organic matter, we know—whether they are united as a compound of silver *we do not know*, consequently all our theory as to the fading of the silver may be wrong. I say that the print whatever it may be, whether coloured organic matter, or silver, or the two combined, I say that it resists oxidising agents, which would destroy many other matters whether organic or metallic. But as the silver process is somewhat on its trial to-night, do not let us admit *supposition*—I cannot for one—and if you ask me and press me saying, "do not you see the silver fading about you right and left in every direction?" I say I see all that; and further, that having got before us a good practical process that we can all use, we must discover the true cause of the failure, and not say we must give it up until we get carbon printing to equal it. I have gone further, and said on a former occasion that I believe a silver print will fade unless it is carefully preserved. Then I explain that and say, that photography is full of paradoxical circumstances. A photograph fixed in fresh hyposulphite of soda in 1844, washed only in three waters (and the third water must contain a portion of hyposulphite), has not faded. Then you see what an important principle is contained in that fact. Now I should further say, if that picture had been washed with ten washings would it have faded? Will you, then, not have confidence in pictures that have had ten washings?—and moreover, that having watched such a picture, it is evident that it may be kept in an ordinary portfolio; but we must be careful in what atmosphere we put them, for hydrosulphate of ammonia would change its colour, and make it darker, and thus improve it; but if the action of hydrosulphate of ammonia be continued the picture will fade.

In large towns hydrosulphate of ammonia exists in rooms, and pictures there fade away by sulphuration in bad atmospheres. They are not so good in that respect as carbons, but then am I to give up silver printing because I live in a badly drained house? They do not of necessity fade as far as our experience goes; but should they do so, after all I have said, my position will still be a good one.

Mr. Hughes:—As regards permanency, the early daguerreotypes fixed by gold, still exist in large proportion, compared with the number that was produced, and the daguerreotype, I repeat emphatically, does not fade. There are many old daguerreotypists in this room whose greatest yearnings are for the durability of the daguerreotype; they did not sulphurate, and blueish film was sometimes formed near the edge, but this was effectually removed by the application of cyanide of potassium, and I imagine sulphurisation would be remedied in a photograph by coating it with gold. Did any one ever try cyanide of potassium upon a paper proof?

A Voice:—Yes.

Mr. Hughes:—And what of the print?

A Voice:—Out.

This last monosyllable brought Mr. Hughes to his seat with the suddenness of an electrical shock, amidst much merriment, upon which the Chairman seized the moment of hilarity to remind the meeting that the discussion had been prolonged far beyond the appointed time, and that each side of the question had been fully represented in their meetings.

The CHAIRMAN then stated as follows: I think it is the feeling of the Society that it is very desirable that Mr. Pouncey should go on with his process, and that all who have the time and means should labour to assist him, but that they will still continue to prefer the silver process, which is most beautiful, even remembering the poet's words, that "all that's bright must fade." I remember in photographing a manuscript of Alexandrinus, I noticed that all the material with which the writing had been formed, which I may now say was carbon (and which was the general material of manuscripts) had so corroded the vellum, that the letters were only represented by the actual cutting out of the vellum surface, so that even the most imperishable materials have, after all, only a limited duration. I am sorry to say that even carbon prints are not everlasting. The precaution taken at the British Museum to ensure the safety of prints is increasing; they are constantly obliged to be brought out to the air and dried, and watched with as much care as little children.

I must now convey to Mr. Pouncey the thanks of the Society for the paper which he has read, and wish him every success.

We have also the promise of a paper from Mr. Pretsch, on a kindred subject.

I have now to remind the Society that it is the evening for them to appoint auditors to audit the accounts of the Society for the past year. I must therefore call upon the meeting to appoint two gentlemen to perform that duty, according to the regulations of the Society.

Messrs. Heath and Harrison were then duly elected auditors, and several candidates were ballotted for and duly elected members of the Society.

Several specimens of carbon prints by Mr. Pouncey, with silver prints from the same negative, were exhibited, and though the carbon prints were really admirable, they were clearly not equal to their silver duplicates, and this fact was very apparent, in a couple produced from the negative of a snow scene, in which the exaggerated contrast of light and shadow was most unpleasantly prominent in the carbon print. In a picture of the *Feathers Inn*, at Ludlow, the carbon seemed to answer very well.

There were also exhibited two albums, containing photographic delineations of geological strata, by Mr. Gutch, beautifully executed; specimens of Mr. Hardwich's toning process, very beautiful in effect; two lithographic stones, engraved by light (a positive and a negative), by Mr. Pouncey; and a telescope, by Herr Pretsch, having one of Petzval's new photographic lenses mounted as its object glass.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

AT the ordinary monthly meeting held at Myddleton Hall, Islington, on the 29th Dec. 1858, G. SHADBOLT, Esq., Vice-President, in the chair. After the usual routine business, Mr. Shave exhibited some photolithographs which he had produced in consequence of the remarks made on this subject at the last meeting. He had had no previous experience, and found the operation very simple. He worked upon the principle patented by Cutting and Bradford of Boston, U.S.*

Mr. HANNAFORD objected to the *principle* of the process tried by Mr. Shave, as not admitting any "touching" of the stone, and thought it would be easier to remove grease than gum from the stone, hence he would work in another direction. He objected equally to the principle patented by M. Poitevin, as in that case the ink was adherent not to the stone itself but to the hardened organic matter on its surface. He proposed beginning by greasing the stone, coating this with the sensitive surface, removing the grease where not required, and then the protecting gelatine or other organic matter acted on by light, thus leaving the greasy parts, previously protected by the hardened coating, to receive the ink from the roller.

Mr. HISLOP then read a paper by Dr. HILL NORRIS, "*On the Dry Processes*," [see page 15] on which a discussion ensued, in which Messrs. Hill, Shave, Hislop, Hannaford, Rev. John Winter, and the Vice-President took part, and was principally directed towards the greater or less amount of washing which dry collodion plates would bear or require.

It was also noticed by the last-mentioned gentleman, that Mr. Maxwell Lyte had, some years back, suggested the probability of there being two or more compounds of the iodide with the nitrate of silver, as now remarked by Dr. Norris. It was further remarked, that Dr. Norris was the first to announce the *principle* upon which success with dry collodion is dependent.

* As first essays the specimens were very good, even a portrait (a difficult test), being infinitely superior to most of the woodcuts.—ED.

Mr. HANNAFORD next read a paper "*On a New Iron Printing Process*," [see page 24] and exhibited numerous specimens produced by it, and hoped by the next meeting to be in a position to exhibifurther and even more favourable results.

Mr. LEGG presented some beautiful photographs of microscopic objects, and promised to explain (and if possible demonstrate) his mode of operating at the next meeting.

Mr. HISLOP also promised to read a paper "*On the History of the Dry Processes*" at a future meeting. Votes of thanks were passed to Dr. Hill Norris and Mr. Hislop, Mr. Hannaford and Mr. Legg, and after further discussion on the subjects brought forward, the meeting was adjourned until the 28th instant.

It was determined at a committee meeting, previously to the ordinary sitting, that as some misapprehension had been found to exist in consequence of a *professional photographer* having an establishment upon the same premises as those in which the meetings of the Association are held, an advertisement should be inserted in the local papers, to intimate that the North London Photographic Association is *not in any way* a trading concern, and totally unconnected with the practice of photography for gain.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A MEETING of the above Society was held at the Literary and Philosophical Society's Rooms, on Wednesday, the 5th instant, Mr. SIDEBOTHAM in the chair.

A new member was elected.

Mr. OXLEY exhibited a gasholder for the supply of oxygen for the lantern.

The PRESIDENT called the attention of the meeting to a number of carbon prints by Mr. Pouncey's method, taken by Mr. Mudd, which were handed round for inspection. He said he considered the specimens shown quite equal to what Mr. Pouncey had produced; he thought that gentleman's specimens very poor, and if he could not produce better prints, the process was very unsatisfactory.

Mr. WARDLEY said he thought the more delicate details of the sun-prints could not be obtained by Mr. Pouncey's plan, and he considered it very far short of what was required.

Mr. MABLEY said he had tried Mr. Pouncey's plan for some time past, but had now resolved to relinquish it.

A long conversation took place as to toning with sel d'or and alkaline baths; also as to Mr. Maxwell Lyte's plan of sulphate of soda.

The PRESIDENT called attention to the subject of developing by daylight, after dissolving the iodide of silver, and remarked that it was a curious fact, that it was only a collodio-albumen plate which could be developed after the fixing, and that several members who had tried had been unable to develop plain collodion; also that after fixing with cyanide it seemed impossible to develop any.

Mr. H. YOUNG stated that he had been able to develop after fixing with cyanide, but thought it required much longer time and showed a picture so produced.

A long discussion followed as to the theory; and

The PRESIDENT said he had examined the film of an exposed plate after fixing, under a powerful microscope, but could not see any trace of the picture; and that Mr. Nield, a member who was absent that night, had been trying a new process, called the "*Treacle Posset*" process, and had obtained some very good results. The plan was, to obtain serum of milk, by breaking milk with treacle and acetic acid. This idea had occurred to him from a suspicion that Dr. Hill Norris's plates were prepared by serum of milk. It had occurred to him, that the council might get up a stereoscopic magazine, from photographs taken by the society, for distribution among the members, and the idea seemed to be approved of by the meeting.

A further discussion on the subject of printing took place.

Mr. MABLEY said he (the other day) looked at some prints taken by him a long time since by gelatine and chloride of silver, and developed, and they seemed as good as ever. After discussing the method of washing prints, it was considered that a short washing of an hour or two was better than a long one.

A vote of thanks was passed to the President and the proceedings closed.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held in the Odd Fellow's Hall, on Tuesday evening, the 28th ult. WILLIAM HOWELL, Esq., one of the Vice-Presidents, occupied the chair.

A new member was admitted in the person of Akers Edwards, Esq.

The Hon. Secretary, Mr. Haines, read an interesting paper "*On the Uses and Abuses of Photography.*" The first branch of the subject was cleverly treated—the use of the art as a means of taking portraits and views, decorating the walls of a dining or drawing-room, serving the interests of science, aiding in the detection of criminals, &c., being pointed out in detail. As to the "abuses" of the art, he said:—Let us suppose a person fired with enthusiasm for the art; he takes up a newspaper, where he sees advertised, "A set of apparatus, with chemicals complete, for 30s." He rushes to the shop of the advertiser, purchases his apparatus, never stops to think if he knows any thing about the process, but stumbles over every part of it, until he gives it up in despair, and abuses the art to all his friends, just because he has been unsuccessful. It may be, that having purchased a shilling pamphlet, "Photography made easy," he at length masters its contents, and can take an image fairly in the camera. He at once considers himself an artist, but it is not so: a man may be a photographer indeed, and may be able to take likenesses, but it requires much more than this to become that great essential to the true practice of photography—an artist. If such a person is taking a portrait, he cares not for the posture of the sitter, which way the light falls, or the colour or description of the background; or if he has progressed so far as to have a background painted in imitation of a landscape, he thinks nothing can be better. But as you all know, the beauty of a portrait is not only in the background, or in the distinctness of the figure, but it consists in having that depth of shadow and roundness of the features so seldom discerned in the generality of the portraits taken in the present day, and which can only be obtained by a proper management of the light. Thus, then, I consider that a want of a proper knowledge of the art, a want of intimacy with the necessary chemicals to be used, and a want of the true artistic spirit necessary to make the good photographer, are some of the chief abuses to which photography is exposed.

Another great abuse is the frightful exhibitions now to be seen in almost every street in most towns in England, to which notice is requested by a voice, which announces that there you can have "a correct likeness and frame complete for sixpence!" Indeed, I heard the other day of one spirited individual, who seems determined to cut all the others out, and who has reduced his price to the "low charge of twopence." The pictures shown in these exhibitions are really "frightful," and it is frightful to see how low one of the noblest arts can be brought by a parcel of unscientific men, who have perhaps left their shopboard or their bakehouse, to become what they are pleased to designate themselves on their address cards—"photographic artists." Many of these, not content with simply perpetrating such vile things as their portraits usually are, make ugliness still uglier, by daubing them with paint, for which they will inform you they charge "sixpence extra."

Another abuse of photography consists in the indecent and disgusting pictures which are exhibited in many of the windows in London and elsewhere. You must lend your aid in causing the discontinuance of those abuses, which are so fatal to the well-being of the art. The formation of such Societies as this I consider the first step towards the safety and progress of photography. The exhibition last year was, I think, very likely to benefit the art here and elsewhere, as until then most people thought that photography was only intended for portraits. By a regular attendance at the meetings, by reading papers on practical subjects, by contributing pictures to the album of the Society, and in other ways, we may do much to promote the interests of our art.

[These last points were enforced at some length.]

Mr. Akers Edwards said, that in the paper just read, one "abuse" had not been mentioned: he referred to the mode in which photographic pictures were often pirated. He knew a gentleman who had spent £1200 in acquiring a knowledge of the art, making experiments and taking pictures; and having lent some of his negatives to a certain Society, he now found that reduced copies of them were on sale in London. As to the indecent stereoscopic slides of which Mr. Haines had spoken, he was informed, a few days since, that a number of gentlemen had formed themselves into a society for suppressing them.

Mr. Osborn (Treasurer) — The views taken by Frith in Egypt were pirated, but they were not so clear as the originals.

Mr. Edwards — It is impossible, when copying them the same size, to get rid of a little granulation. Of course, by entering photographs at Stationers' Hall they are protected from piracy.

Mr. Osborn — It is sometimes difficult to tell your own negatives, in transparent pictures especially. I saw a set of pictures offered for sale some time since, not one of which was printed from the original negative. Rejlander's *Home sweet Home* is mentioned in the paper, and I may state that this picture is singular as being an application of photography to artistic purposes. The picture was made from eight distinct negatives, taken in different parts of the country, so that it is entirely a composition. It is so beautifully worked together, that you cannot distinguish the separate parts. Clouds, water, and foliage, were taken at different times. As to the employment of photography for astronomical purposes, I may mention that it is in constant use at Greenwich, for registering the variations of light from the sun, and for other purposes. Mr. Haines alludes to photography having almost reached its crisis.

Mr. Haines — No: I meant to say, that if we do not take care it will go down.

Mr. Osborn — Well, one result of its going so low will be, that it will drive out all except those who are really artists. I hope that now the price has gone down to twopence it will go to one penny.

After a few further remarks, a vote of thanks was passed to Mr. Haines on the motion of Mr. Osborn, seconded by Mr. Brown.

Mr. Osborn having announced, that at the next meeting a paper would be read by Mr. Morris, the proceeedings closed.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.

The ordinary monthly meeting of this Society was held in George Street Hall, Edinburgh, on the evening of Tuesday, the 11th instant. The attendance was limited. Mr. Johnston occupied the chair.

Discoveries in Photography.

Mr. Taylor, South Bridge, read an interesting paper on this subject. After a few prefatory remarks as to the fertility of the question, and the rapidity with which new and startling discoveries were brought to light, Mr. Taylor said, that in his opinion three men only were entitled to place in the foremost rank of early photographic fathers, viz — Daguerre, Nicephore Nièpce, and Fox Talbot. Through the discoveries of these eminent men the art of photography had attained its present high status. While he could not recognise in the experiments of Wedgwood and Sir H. Davy any peculiar grounds for the great merit usually attached to them, it was quite different with Scheele, who, in his experiments, subjecting the silver salts to the action of the prismatic spectrum, first struck out a path different from that previously trodden by the old alchemists, who seemed to rest satisfied with a knowledge of the fact, that certain salts became rapidly nigrescent on exposure to light.

Although the discovery was attributed to Ritter, he thought it seemed scarcely probable that such a close observer as Scheele could have failed to see the now well-known actinic action of the highly refrangible dark rays, beyond the violet, in the spectrum. If he did observe this peculiar property, he made no mention of it in his researches, which were published in the year 1777. Ritter made this interesting discovery in the beginning of the present century.

The first to enter the field of active photographic discovery, was N. Nièpce, the main feature of whose discovery was, that certain gums were so changed in their constitution by an exposure to light as to become quite insoluble in menstrua, in which they readily dissolved previous to such exposure. N. Nièpce was the father of all such as employ bitumen or analagous substances in photolithography, photographic engraving, and direct positives on white metal plates. The large photograph by Mr. Macpherson, in the Society's Album, was an illustration of his process.

Daguerre's beautiful process quite took the scientific world by surprise the extreme minuteness, fidelity, and beauty of his pictures, exciting unbounded admiration; nor was this to be wondered at, for even in the present day, when the eye was accustomed to all that was beautiful in art, a well executed photograph never failed to excite sentiments of a pleasing kind. Pity it was (continued Mr. Taylor) that the process of Daguerre met with so few adherents, but perhaps this was attributable to the labour of polishing the plates. Veteran photographers still looked back on this, "their first love," with feelings of fondness.

Of the importance of the discoveries of Fox Talbot, they were all aware. To him photography owed the Talbotype or calotype process,

the waxed paper process, the albumen process, the general process of printing positives from negatives, the process of printing positives by developement, and lastly, the art of photoglyphic engraving. The ball of photographic discovery having been thus started, had kept rolling on until photography had reached its present gigantic stature.

Mr. Taylor then referred to the many sub-discoverers in the art, whose names would, he said, be imperishable in the annals of photography. Having apologised for the omission—an unintentional one—of many names well deserving of notice, he said we were indebted to Archer for the collodion process,—a successful method of removing the collodion film from glass, and the process for producing the white positives on glass, now called the "Alabastrine Process;" to Becquerel for scientific investigation in polychrome photographs, in the exciting and counteracting action of certain rays, &c.; to Beauregard for the process, now called the "Ink Process" of printing positive photographs, and for the successful production of polychrome prints. To Sir David Brewster we owe the refracting stereoscope; to Berry, leather as a substance on which to take collodion processes. To Burnett we owe a lot of investigations on the photographic properties of the salts of iron, copper, chromium, uranium, and others; for band and coloured lenses; for a discovery by which the strength of paper is very much increased, by being converted into a species of parchment; for the discovery of leather varnish, on the surface of paper, and the action of tannin and gelatine; for toning positives by neutral and alkaline chloride of gold baths, rendering over-printing unnecessary; for the successful application of ammonia as a substitute for hypo-sulphate of soda in paper processes; for the suggestion of burning-in uranium and other photographs, in presence of an atmosphere of hydrogen or other reducing agent, in order to obtain dark colours. To Church we owe the pneumatic plate holder; to Claudet the discovery or application of chloride of iodine in daguerreotyping, an instantaneous printing process in which chloride of mercury is employed, and the invention of the whole lens stereoscope. To Crookes we owe varied scientific investigation of a highly interesting character in polarised light and the prismatic spectrum, and, with Mr. Spiller, the first successful application of an attempt to preserve the sensitiveness of collodion plates. Edwards first transferred the daguerreotype to paper; Fyfe was the first to produce positive pictures on paper by one operation. To Fizeau we owe the discovery of hypo-sulphate of gold as a fixing agent for daguerreotypes. Fothergill discovered a dry collodion process, in which the albuminate of silver is employed. Gaine invented a process for the conversion of paper into a species of parchment. Gaudin gave us cyanide of potass as a substitute for hypo-sulphate of soda in fixing glass positives. Goddard first applied bromine to increase the sensitiveness of daguerreotype plates. The numerous and important researches and discoveries of Herschel and Hunt would require to form the subject of a separate paper. Johnston was the first to impress photography into the service of wood engraving. Laborde discovered the addition of salts of lead to allow gallic acid to be used in developing collodion pictures. Lafond discovered the application of photography to ceramic decoration. Le Gray invented the waxed paper process. Lyte discovered an instantaneous collodion process, with prolonged time of keeping before exposure; also for the application of meta gelatine as a preservative agent. Llewelyn gave us the oxymel process—a slight modification of Shadbolt's honey process. Malone made philosophical researches in photography. Moser's name was associated with the introduction of thermography, although he (Mr. Taylor) believed it owed its discovery to one of his own profession, a watchmaker in France. Nièpce de St. Victor perfected the process of his uncle, N. Nièpce, and made many experiments in photography, especially in the higher branches of it. We owe to him the albumen process on glass, and the discovery of some very wonderful properties in iodine. He (Mr. Taylor) believed he had also succeeded in producing polychrome pictures. Noton invented a beautiful adjustable stop for the front of the lens. Norris gave us the now deservedly popular dry collodion process. Petzval was the author of the double combination of lenses for portraits, and also of the orthoscopic lens for landscapes; Ponting gave us bichromate of potass; Pouncey, carbon printing; Pretsch, photogalvanography; and Poitevin, a highly successful system of photolithography. Salmon and Garnier discovered a system of photographic engraving, based on the affinity of mercury for those parts of an iodized brass plate which had not been exposed to light. Shadbolt was the father of micro-photography, and of all those who used saccharine preparations for the preservation of collodionised surfaces. Stokes made the discovery of fluorescence, or the rendering visible the refrangible dark rays in the spectrum. Sutton gave us a highly satisfactory and popular mode of producing prints by developement. To Taupenot they owed the collodio-albumen process; to Wheatstone, the reflecting stereoscope; and to Woods, the catolysotype and other beautiful processes little known at present.

When on the subject of modifications and re-discoveries, he instanced Mr. Shadbolt's honey process as the one which, more than all others, had been subjected to undergo most modifications; none of which seemed to be any improvement on the original, and many of them much inferior. One discovered that sugar and water was a substitute for honey, and he aspired to immortality as the discoverer of the sugar and water process. So with the sweet wort process, the raspberry vinegar process, the glycerine process, the sour ale process, and other "processes" *ad nauseam*, until matters were fairly brought to a climax, by a side-splitting communication from Manchester, which satirically detailed the history and virtues of the discovery of the great "gin and water process."

He stated that the uranium discoveries of Mr. Burnett had been the subject of a *re*-discovery of Nièpce's; with this important difference also, that Burnett's was very much superior to Niepce's. The most glaring case seemed to be that of the discovery of the ink process of Beauregard, which was re-discovered and patented in this country a year after it had been published in the *Journal of the Photographic Society*, re-discovered and published as new a year after it was patented, and again re-discovered and published *as new* a few months ago!

A brief discussion ensued on the subject of Mr. Taylor's paper, in which Mr. Tunny claimed the first application of collodion for Le Gray.

In reply, Mr. Taylor stated that while granting that Le Gray was the first to employ collodion, he claimed for Archer the process as practised in the present day.

A vote of thanks having been awarded to Mr. Taylor for his paper, the meeting adjourned.

Exhibitions.

NOTES ON THE EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF SCOTLAND.

SECOND NOTICE.

[From a Correspondent.]

In my last, addressed to you from Scotland, I gave you a brief notice of the principal or leading pictures, but scarcely touching those of Scottish artists, save one or two — to which I will now return, if you find my remarks sufficiently interesting to your readers.

I closed my last letter by an allusion to Maxwell Lyte's six pictures, Nos. 965 to 970. Four are by the wet collodion process, two by metagelatine. They are about equal in minuteness of detail, fine perspective, and richness of foliage, with the mountains towering aloft in the distance, "lending enchantment to the view." The skies are evidently from separate negatives, but skilfully printed, greatly enhancing the beauty of the scene. They are softer and sharper than those of Mr. Raven's of the same scenery; but not apposite to compare, the one being by waxed paper, the other by collodion. No. 969, "Le Sac Bleu de Bagneres," is exquisite, very similar in tone to Rejlander's "Loch Katrine," both in the still water and lichened rock on the spur of the hill. They are toned with phosphate of gold.

Mr. H. Ross (who is, I believe, Vice-President of the Photographic Society of Scotland) exhibits a gigantic quota, no less than *fifty* different subjects. Some are by the wax-paper process, and some by collodion. Nos. 481 to 484, "The Happy Days when we were Young," are studies of frolicsome juvenility, such as shooting and fishing during schoolboy vacations, calling up reminiscenses of days long gone by, never to return to those engaged with the sober realities of life, but on the page of memory.

There are among this gentleman's contributions (who follows in the wake of Landseer) several sporting pieces, with deer, that would make fascinating studies were the composition in keeping with the subject. No. 390, for instance, has a mere blank paper sky, but would make a good picture if the details and other accessories in the foreground and distance were suitable. I think Mr. Ross might make charming groups if he would try printing from various negatives like Rejlander or Robinson, not altogether the barren waste or bleak mountain side, but from some warm corrie or glen, with gorse, stunted shrubs, and trees for a foreground, and for distance the undulating mountain scenery abounding in the Highlands of Scotland, or following the language of the poet—

"The rugged mountain's scanty cloak,
With dwarfish shrubs of birch and oak,
With shingles bare, and cliffs between,
And patches bright of broken green."

From the large number of pictures sent by this amateur I would infer that he is enthusiastic, and not to be deterred by trifles from accomplishing what he has set his mind to do — once surmounting his present bias, he

will send no more Royal Stags, with a skyless, distanceless, background. No. 789—"Infantry in Column," is a good picture, though a little out of focus at the margin: the men have been very steady, as is the wont of the British when called to duty. The waxed paper in the hands of this artist is not quite up to the mark, though he exhibits a great variety by that process. I was informed that he had heretofore worked only with collodion, and think he would do well to adhere to his *first love*.

Lyndon Smith's views on the "Rye," (Nos. 443 to 446,) and "Woodlands on the banks of the Rye," are fine studies, with good clear distance.—No. 737 is dense, thick, feathery foliage, yet has fine ærial effect, the light playing through among the stems on a sloping bank.

Mr. Lamb, of Aberdeen, contributes ten pictures. No. 743, "Castle Street, Aberdeen," is excellent, sharp and clear. He has also several good landscapes.

William Walker's (Nos. 97, 381, 531) "Dalhousie Castle," and views on the "Esk," by the calotype *(old school)* process, are very good; Nos. 531 and 535 are pictures of the same spot—the waxed paper one by Mr. Kinnear is much larger, but it is not so well printed, or is from an inferior negative.

No. 582, by C. Silvy, "River Scene in France," exhibited by Murray and Heath, London, is a singular picture, with a dark thunder cloud ready to burst, black as midnight, yet clear and transparent in the shadows. Is this a true portrait of that country? Is it a method of speaking out, yet escaping the fate of a political martyr? To these questions I cannot reply, as I do not profess to be able to solve such enigmas; but as a picture it has my approbation.

"Laymouth Castle" (Nos. 65 and 66), by Mr. Craigie, is a noble pile of building, but the outlines are too sharp and hard. I hope he will do something better on a future occasion.

Mr. Pouncey has found his way across the Tweed, notwithstanding the scene in London on a late occasion: he is represented by one solitary specimen, No. 578. I assure you if the advertised specimens at a guinea are like this, I shall button my pocket, and reserve my guinea for something better. It is harsh and hard, without gradation of tone, and few would regret its "*fading away*." The carbon process will not become universal, even though it does promise permanence, until, in competent hands, it educes something very superior to that now exhibited in Edinburgh.

F. Bedford shows some exquisite pictures of buildings by the collodion process, principally ruins, with ivy clambering over them; they are all purchased by the Society, and I believe are got up for the Architectural Association. Fenton exhibits several large landscapes of Scottish and Welsh scenery, well-known to most photographers throughout Britain. B. B. Turner, and J. H. Morgan, Bristol, excel in woodland scenes; it would be difficult indeed to over-praise them, they are so faithfully translated—so perfectly true to nature.

There are also several lady photographers, who work by the collodion process, and are not afraid to be seen with silver stains upon their fingers. Miss Ann Taylor (professional) exhibits twenty pictures. Nos. 581 and 696 are comparable with the great majority of proofs in the saloon: "Entrance to the Falls of Moness," with a fine rustic bridge, is as choice a landscape as one could desire, and a brilliant impression.

Even in the cold, frigid north of Scotland, this fascinating science has its devotees. Sutherlandshire sends its views of the Helmsdale by Mr. Houstoun. Every village and hamlet through the length and breadth of Scotland seems to be inoculated with a desire to promote the fine arts, by exercising their talent in producing pictures through the mysterious actinic power of light, so lately developed out of the darkness of bygone centuries.

Before leaving the landscapes, we must notice some to which our attention was drawn, *not in the Exhibition*, but in Messrs. Ross and Thomson's case, at the bottom of the stairs leading to their rooms. They are very large botanical studies, perhaps about 16 by 16, fitted to form splendid foregrounds for artists: they are described by Sir David Brewster in the *North British Review*, a quotation from which I have copied out, and is as follows:—"Messrs. Ross and Thomson published some time ago the most beautiful photographs of plants for foregrounds, taken while growing at the foot of rocks and trees. Of these, the ferns, the dock leaves, the foxgloves, and the nettle, are beyond all praise; but charming as these are, they are surpassed by two on a larger scale, which have recently appeared under the name of 'The Quiet Corner,' and 'The Dike Side.' These photographs, 15 by 15½ inches, full of the poetry of vegetable life, teem with wild plants of the most picturesque lovely forms, and are rich in the variety and luxuriance of leaf and stem. Though devoid of fragrance and of colour, they allure us to the cooling fountain which waters them: they tempt us to nestle in the little rocky hollow which they adorn, and to weep with human sympathies amid creations that are fated but to bloom and die." In the Exhibition there are none of this class that will for a moment compare with them, and I send you the quotation from the pen of the President, as preferable to anything I could give you.

In the Exhibition there are shoals of portraits, but these have little interest out of the locality. Some are touched, some are painted, some are enlarged to the size of life; many have eyes put in, while others have no eyes at all. I examined minutely a considerable number of these, and would place first and highest on the roll those exhibited by Mr. Rodger, of St. Andrew's: they have a delicacy and beauty of finish, are soft, chaste and posèd in a dignified attitude. No. 667 is a "Portrait of a Lady," to which I refer as a specimen.—Messrs. G. and D. Hay send a large number of excellent portraits. No. 266 is a good example of their work, and I am persuaded they are purer photographs than those of any other large contributors to the Exhibition. Their positives on glass are well known, and highly appreciated in Auld Reekie.

Maull and Polyblank send thirty-five specimens of portraits, not one being marked as touched, while I am persuaded every one is tampered with more or less. I am acquainted with a gentleman who unmounted a copy of Macaulay's portrait, issued by that firm, and found it to be almost entirely painted over with sepia, which being removed by the washing, left the historian's countenance somewhat unsightly. They are very creditable specimens of *art*, when touched up and hot-pressed, but miserable photographs. The great bulk of the portraits exhibited are in this condition. Mr. Moffat's, I believe, are less so than either Claudet's or Maull and Polyblank's, but they are certainly touched.

Mr. M'Leay exhibits a touched and an untouched photograph, side by side: this is as it should be, and renders the competition fair and honest. Mr. Tunny's portraits are less touched than some others, but some of them want life and light in the countenance; they look in a brown study, with downcast eyes, as if meditating on the pains of impecuniosity or other dismal state. Mr. Valentine, of Dundee, sends some about half-life size: I always find the smaller portraits most faithful. It is impossible to go over the whole. There are specimens from Messrs. Nelson and Lamb, of Aberdeen, Mr. Dounnie, of St. Andrew's, and various others. I was glad to have an opportunity of seeing them. I was greatly pleased with the Scotch Exhibition as a whole, and will do myself the pleasure of endeavouring to conjoin business with amusement, and pay it another visit on some future occasion. SEL D'OR.

NOTTINGHAM PHOTOGRAPHIC SOCIETY.

AWARD OF PRIZES.

To the Council of the Nottingham Photographic Society.

2, *Upper Hornsey Rise, N., Middlesex.*
4th, January, 1858.

GENTLEMEN,

Having been appointed by you to report upon the respective merits of the various contributions from your members competing for the prizes offered by your Society, with a view to the encouragement of excellence in the practice of photography, I have to make the following observations, viz.—

I have carefully inspected each and all of the specimens submitted to me, and find a considerable degree of merit in many, not to say most of them. There are,

Of pictures 10 in. × 8 and upwards in dimensions, *eight* class A.
Of those 8½ in. × 6½ and under " " *five* " B.
Of double stereographic pictures ... ... *fifty-seven* " C.

I am instructed by you, that

"The various qualities, including artistic composition, which characterize excellency in photography—without reference to the process—are to form the basis for the adjudication of the prizes."

The above regulations, though readily enough applicable to classes B and C, present a difficulty with class A, in consequence of each of the two pictures competing being deficient in only one point.

The selection lies between "West Door, Southwell Minster, September, 1856," by the Rev. J. J. Dredge, and "Regent Street, Nottingham," by Mr. J. Bourne.

The negatives from which the former have been printed, were produced by the calotype process, and the lens employed for the purpose was evidently very far from perfect, a considerable amount of distortion in the marginal lines, especially at the upper part of the picture, being apparent, and the angles weak. It is however very artistic in treatment, the process employed well adapted to the subject, and the manipulation, both of the negative and positive proof therefrom, is probably as perfect as the means employed would admit of.

"Regent Street, Nottingham," by Mr. Bourne, is admirably executed in every particular, so far as regards manipulation. The negative, clearly on glass, appears to have been taken with a *very good lens*, applied with considerable skill, the near and distant objects being both properly defined and in correct proportion, the perpendicular lines at the margin of the picture free from distortion, and finally, the printing of the positive impression performed in a highly satisfactory manner. It is, however, very questionable whether the application of so much skill to the delineation of a *mere street view*, possessing very little of architectural interest, and totally destitute of every vestige of life, is not labour thrown away. It is true, that in the treatment of the subject every thing has been done which could have been accomplished, with the exception of the introduction of living objects; but with such a subject as that under consideration, this deficiency is a serious one.

I find, also, that the rest of this gentleman's pictures are nearly if not quite equal in manipulation to that mentioned, though all of them are somewhat deficient in the *artistic element*.

It is rather a point for the donors of the prize, than for me, to decide whether artistic excellence with as good manipulation as the means employed will admit of—or better manipulation by superior appliances, but somewhat wanting in the artistic quality—shall take precedence.

It may be contended, that the operator has the opportunity of selecting his tools; but on the other hand, so he has of selecting his subject, and what is of as much importance, his *point of view*.

I have however no objection to make to the latter in either of the two pictures in question.

I should prefer that the authorities of the Nottingham Photographic Society should decide as to which of these qualifications they are most desirous of encouraging; should they require an expression of opinion on my part, I shall not shrink from giving it, but I most decidedly object to assuming anything like arbitrary dictation in the matter.

In Class B there is no doubt upon the selection—the old castle, water, and bridge, sent in by Mr. T. F. Hurley, is far the best in this class in every point.

The stereoscopic subjects, Class C, are unusually good, and possess merit of a very high order as regards treatment, manipulation, and artistic excellence; indeed this latter quality is rather the rule than the exception amongst the fifty-seven specimens competing. I would mention particularly —

Southwell Cathedral, by E. S.

No. 7,—Bursley Park .... No. 9,—Llanrwst .... No. 24,—Wilford .... No. 27,—Wothorpe .... No. 29,—Wilford .... No. 31,—Peterborough Cathedral	By Mr. Woodward.
The Pagoda, Alton Towers .... Lady Mary's Terrace, Alton Towers ...... South Doorway, Shetley Chapel...... ..... Trunk of the Mejas Oak, Sherwood Forest	By the Rev. James J. Dredge.

Out of so many that are really excellent, it is a task of some little difficulty to select the one which can be regarded as absolutely the best. I have however no doubt at all that Mr. Woodward is fairly entitled to the preference, for though the specimens sent by Mr. Dredge are exceedingly good, they are not quite equal in manipulation to those of Mr. Woodward, which have equal artistic merit.

Mr. Dredge's negatives are apparently somewhat under-exposed or over-developed (possibly a little of both), owing, in all probability, to his being accustomed to the calotype process, which is peculiarly adapted to the treatment of subjects requiring rather a bold style.

Of Mr. Woodward's specimens, though all six that I have named are especially fine, the one that I select as most deserving is that numbered 29, Wilford, a landscape, consisting of a labourer's cottage with thatched roof, having a white gable end as the prominent feature in the picture: the shadows of the projecting parts of the thatch, of the old gate, and various protuberances, are beautifully transparent; the definition of the foliage in the background is very distinct, without the least snowiness of effect so frequently present; the cottage on the left in shadow, and the subdued tint of the foreground, are in "perfect keeping;" while the well-broken sky line, and delicate gradation of tone every where perceptible, unite to form a very charming composition.

I trust, that if I have not been able to perform my task with perfect satisfaction to every competitor, each one will perceive that I have endeavoured to do it with integrity to the best of my ability; and as I have given reasons for the conclusions arrived at, it is competent for others to judge of the soundness or otherwise of my views.

With best wishes for the success of your exhibition, I am, gentlemen, your very obedient servant,

GEORGE SHADBOLT.

In consequence of the above report the following letter was received by the writer:—

Dear Sir—I am directed by the Council of the Nottingham Photographic Society, to convey to you their warmest thanks for your examination of the competing works, and they will feel gratified by your publishing the report.

The Council will also feel obliged if *you* will name the picture which you consider most worthy of the prize, as they have left it *entirely to your decision.*—I remain, dear Sir, your's most respectfully,

FRED. R. FUSSELL.

Nottingham, 5th Jan. 1859.
George Shadbolt, Esq.

OUR REPLY.

Mr. Dredge's manipulation being as perfect as the circumstances *would permit*, it is to be presumed that had his lens been a better one, and his process one in which glass forms the support, his manipulation would have equalled Mr. Bourne's; while there is no evidence to lead us to expect that the latter possesses an equal talent for artistic selection; but *setting aside these considerations*, although very unwilling to pass over manipulative skill like Mr. Bourne's, I am constrained to admit, that inasmuch as artistic skill is of vital importance in the production of a pleasing result at all, and conjoined as it is in the case before us with great mechanical dexterity, I think Mr. Dredge is fairly entitled to take precedence. I wish it were in the power of the Council to award a second prize to Mr. Bourne, as I consider it would be well bestowed.

GEORGE SHADBOLT.

Processes.

IRON PRINTING PROCESS.

By Michael Hannaford.

Just at the present moment some little interest is felt in the discovery of new printing processes, to supersede *in permanency* the ordinary silver prints. In this, I doubt not, we shall succeed; but there for the present we must stop. Silver prints, in my opinion, will not for some time yet to come be equalled in beauty and delicacy by any other process now before the public.

In the iron printing process which I now purpose placing you in possession of, I do not at present claim equality with the silver prints in any one point, excepting that of permanency. It is (I am quite certain), however, capable of very great improvement, as I hope to be in a position to show at your next meeting.

To make the process as plain as possible, I will divide it under four heads—Sensitizing, Exposure, Fixing, and Toning and Developing.

Sensitizing—Float for about one minute on a solution prepared in the following manner—Fill two pint bottles, one with a saturated solution of bichromate of potassa, the other with from ten to twenty (say fifteen) grains of ammonio citrate of iron to the ounce of water. Mark one A and the other B. Then to A add a quarter of a pound of gum-arabic and half a dozen lumps of sugar. Two measures of A to one of B makes the solution of about the required strength. This however depends somewhat on the kind of paper used. If too much of the gum solution be added, the film will wash off in some parts in the after operations of fixing and toning, &c., whilst an insufficiency causes a want of vigour and depth of tone in the shadows. The most advisable plan for a beginner to adopt, is to commence with, say, equal parts of the solutions A and B—this will give a very weak picture—and add solution A by degrees, trying a picture between each addition until he has reached the maximum quantity of it that can be used with safety. A little care and experience at this part of the process will tend greatly to success. Ordinary albumenised paper answers best in my hands.

Exposure—A longer exposure is required than for a silver print. The picture should show of a dark brown ochre colour and give full definition and half tones. Only good negatives, full of definition and half tones, rather over-exposed than otherwise, should be used.

Fixing—Immerse in water to soak out the bichromate of potassa and ammonio citrate of iron not acted on by light. The exact time it remains there is not of much consequence. From half an hour to an hour will do. After taking the print out of water, I find that a very weak solution of ammonia (about one drachm to the pint) tends materially to keep the whites pure.

Toning and Developing—The ease with which almost any tint of the silver prints can be closely imitated in this process in the course of a few minutes entitles it I think to some degree of

favour. Pyrogallic acid, solution of tannin, or saturated solution of gallic acid (I generally use the latter) poured over the picture gives a warm sepia tint. A very dilute solution of chloride of gold, before the gallic acid, changes this to the gold purples of the silver prints. The gold can be superseded by the salts of manganese, copper, uranium, &c., by which the tint may be varied. Ferro-cyanide of potassium and gallic acid gives Prussian blue. The ferrid-cyanide, &c., produces blue black. But more on this part of the process at a future opportunity. I must ask your indulgence for this process as it stands at present for it is very far from being perfect. By your next meeting I hope to be able to give you full particulars on minor details, and more especially on the best kinds of paper to be used, and on the different toning processes.

Letters to a Young Photographer.

No. II.

My Dear Eusebius,

There is no such thing as "science for beginners." When you enter upon the study of a new subject, such as photography, you must expect to encounter many things which at first you cannot understand. You are like an infant who opens its eyes with dawning intelligence upon a world in which every thing is new; and the progress of understanding is slow, and, as I said in my last, is based upon experience. You wish to know the why and the wherefore of all you do in pursuing our art, which is a very laudable feeling, and one that I shall do my best to encourage and satisfy. You ask, why you are to mix water with the albumen? I answer—to dilute it, to reduce its strength, to make the paper less glossy; and you say you cannot get your paper glossy enough. Now the amount of gloss is a matter of taste. Some people cannot eat gingerbread unless it be gilt: they think they are eating pure gold while it is only copper. You may print pictures on plain paper, if you like it, but they will look dry, because for want of a little glaze there will be no transparency in the shadows, and unless these be transparent, they will have no depth, and consequently your picture will seem dry and flat. But the quantity of glaze necessary to secure this transparency is very small, and when you exceed it, you produce the effect of a varnish, which is desirable only in very few instances. The prevailing taste for high glaze leaves even pure albumen insufficient to the ends desired, and you will see, and may purchase, albumenized papers in which the glaze is produced by the addition of other matters than albumen, such as gum, gelatine, or dextrine. Even pure albumen, without the addition of water, yields too much glaze, unless the paper is to be used for stereographic pictures: in these the highest amount of glaze is admissible, as when viewed through the lens, the *grain* of the paper is magnified, and impairs the sharpness of the pictures.

Now as to the cause of the spots with which you say your paper becomes covered. Perhaps your albumen became soiled with dust while exposed in the dish, or perhaps the dish itself was dusty when you poured the albumen into it, or perhaps the floor of your room was not well swept before you commenced operations. Dust is a very subtle foe to the photographer, and constantly insinuates itself where it is not wanted, and where its presence is most objectionable. You must not venture to use any vessel until it has been carefully wiped out with a clean cloth kept for that purpose exclusively. You had however better strain your albumen, by pouring it through a funnel with a piece of clean sponge, wetted, placed loosely in its neck; this will effectually stop the passage of all mechanical impurities: and it is as well to keep funnel, sponge, bottle, &c. solely for this purpose; for if you employ them for any other, they may gather up substances that will cause "chemical reaction" when brought into contact with the salted albumen, and so mar your operations.

Paper has a right and a wrong side. The former is the smoothest, and has the highest glaze; the latter shows a *grain*, derived from the canvas upon which the pulp of the paper rests in the process of manufacture. You can easily distinguish the smooth side by holding up a sheet of the paper horizontally before a lighted window and looking along the surface; and it is this smooth surface that you will coat with albumen.

Why do I give the preference to chloride of ammonium over chloride of sodium or chloride of barium? I answer, because it is very important to the success of sensitizing papers that the chloride should be neither acid nor alkaline, but neutral. Chloride of barium I frequently find to be alkaline; common salt is generally impure. Moreover, as the most economical salt to employ is that which contains the greatest amount of chlorine in a given weight, if all the chlorides were sold at the same price the chloride of ammonium would be the cheapest. There is twice as much chlorine in an ounce of chloride of ammonium as there is in an ounce of chloride of barium. As to the colour produced in the positives by various chlorides, it is due not to the base, but to the acidity or alkalinity of the chloride, and the addition of a few drops of an acid or an alkali, will secure any desired result within certain limits. But you will find it better to use a neutral chloride, and that of ammonium has this advantage, it is rarely met with acid, and if it is, you can bring it to a state of alkalinity by the mere addition of a few drops of ammonia solution, and any excess of ammonia will evaporate as the paper dries.

Bubbles? The world is full of them, but the greatest share falls to the photographer while floating paper on albumen. Now, where a bubble adheres to the surface of the paper, a white spot will be manifested upon the printed proof. Therefore, the surface of the albumen must be kept quite free from these tormentors, and a piece of clean paper is all that is required to remove them from the surface. As to the strength of the salting solution, I consider 5 parts of chloride of ammonium to 100 parts of water, a maximum for all ordinary purposes. The time the sheet of paper is allowed to remain floating on the albumen had better be as brief as possible, consistent with completely imbuing the paper with the fluid. You will understand that the strength of the chloride of silver obtained on the sheet in the subsequent operations, is dependent upon the strength of the solution of chloride in this; it is slightly modified by the time occupied with the floating on the solution.

When you remove the sheet of paper from the surface of the bath, it must be done slowly and carefully, to avoid the formation of bubbles; the first drainings may flow back into the bath; the last drippings may be absorbed by a piece of bibulous paper attached to the lower corner of the paper. Use black pins for suspending the papers, as white pins are acted upon both by the salting and the silvering solutions, and a portion of the sheet becomes spoiled.

The paper, thus albumenized and salted, when thoroughly dry, may be kept for use for any length of time, in a drawer, or packed, free from contact of dust or foul air.

In my next, I shall edify you on the subject of sensitizing or silvering the paper.

Photographic Glossary.

Alcohol— or Spirits of Wine—an agent extensively used in photography. It enters into the composition of collodion; and is added to the developing solution, with a view of causing the fluid to flow at once over the plate. Alcohol is a solvent of the resins, hence useful in the manufacture of varnishes. It is also used for burning in the spirit lamp, producing great heat without smoke. Absolute alcohol is 75·25 above proof, and has a specific gravity of .796.

Alkalies—A class of bodies of which caustic soda and potash may be taken as the types. They are for the most part metallic or earthy oxides, possessing the property of neutralizing acids, and forming, by combination with them, an extensive class of bodies termed *salts*. Solutions of the alkalies change vegetable blue colours to green: the yellow of turmeric they change to brown. Volatile alkali is the name given to the solution of ammoniacal gas in water. Alkalies are the most powerful of the class of bodies termed bases. The acid and akaline conditions of solutions require to be carefully distinguished in photography: this is accomplished by means of *test papers*.

Amber—A fossil resin found chiefly on the shores of the Baltic Sea. Dissolved in chloroform it is used for making a varnish for negatives on glass, but cannot be recommended for that purpose, as it is extremely liable to be rubbed off with the slightest friction.

Ambrotype—A name given by American photographers to positive collodion pictures on glass.

Ammonia—A volatile alkali formed by the combination of hydrogen and nitrogen gases. It is very soluble in water: the solution is known as *liquor ammoniæ*. Its alkaline properties are very energetic; it is used in photography as a detergent; for toning in positive printing; and for forming the ammonia-nitrate of silver.

Amphitype — The name given by Mr. Talbot to a photographic process, invented by Sir John Herschel, which produces pictures that are both positive and negative, according as they are viewed by reflected or transmitted light; and to pictures produced by one and the same action of light, which become either positive or negative according to subsequent manipulations.

Analysis — The method by which the constituents of compound bodies are separated from each other, and distinguished by appropriate *tests* or reagents.

Anhydrous — A term signifying free from water. An anhydrous salt is one entirely free from water of crystallization. An anhydrous acid is an acid in its greatest state of concentration; many acids cannot exist without the presence of water.

Aperture — An opening. Lenses of a given diameter and the opening of a diaphragm are said to be of such an *aperture*.

Aplanatic — A term applied to lenses which are constructed so as to give images devoid of aberration.

Aqua Regia — A mixture of hydrochloric and nitric acids, used as a solvent for gold.

Areometer — An instrument for measuring the density of liquids; called also hydrometer, and sometimes densimeter.

Archerotype — A name proposed in honour of the late Mr. F. S. Archer, to be given to the collodion process.

Anthotype — A process in which the photographic agents employed consist of the vegetable juices of young plants and flowers, and of the alcoholic solutions of various resins.

Apparatus — The instruments, implements, &c., with which the operations of any process in photography are carried on, such as the camera obscura, baths, dishes, funnels, &c.

Argentine Salts — The salts of silver.

Argentometer — An instrument for testing the strength of solutions of silver.

Asphaltum — One of the names of bitumen: a substance employed in the early stages of heliography, by M. J. Nièpce, and latterly by M. Nièpce de St. Victor, in photographic engraving.

Astro-photography — The application of photography to the delineation of the celestial bodies.

Avoirdupois Weight — The weight by which all articles of commerce are sold. The pound consists of 7000 grains, while the pound Troy weighs only 5760 grains.

Azote — A name sometimes given to the gaseous element nitrogen.

Barium — A white metal with the colour and lustre of silver: combined with chlorine it forms chloride of barium, used in "salting" paper in the positive printing process.

Baryta — The protoxide of barium.

Base — All bodies which combine with acids and form *salts* are termed bases: the alkalies are the most energetic.

Bath — This term is applied to the various solutions used in photography in which paper and glass plates are immersed: also to the vessels in which the solutions are contained.

Benzole — A colourless, volatile liquid, used in photography as a solvent of bitumen, &c.

Benzoin — Commonly called gum Benjamin: dissolved in alcohol it forms a useful varnish for collodion negatives.

Bichloride of Mercury — Familiarly known as the powerful poison "corrosive sublimate." It is used in photography for strengthening weak negative pictures on collodion, and for weakening paper positives.

Bichromate of Potass — A salt much used in dyeing and calico-printing. It is also the principal agent in Mr. Talbot's process for photoglyphic engraving, and it is used in a positive printing process invented by M. Sella.

Biconcave — A biconcave lens is one in which both surfaces are concave. Such a lens renders the rays refracted through it divergent.

Biconvex — A lens is biconvex when both its surfaces are convex: the rays refracted through it are convergent.

Bromides — Combinations of bromine with various bases: those principally used in photography are the bromides of cadmium and of potassium.

Bromine — An elementary body which at common temperatures is a thin, volatile, red liquid of a very intense colour and suffocating odour. It is slightly soluble in water, more freely so in alcohol, and most abundantly in ether. In combination with other bodies it forms *bromides*.

Bronzing — When positive proofs are over printed the shadows assume a metallic lustre which is termed *bronzing*.

Buckle's Brush — This implement is formed of cotton wool inserted in a piece of glass tube, the cotton projecting. It is employed to spread solutions on paper in the calotype process, &c.

Buff — An implement used in the daguerreotype process for polishing the silvered plates. It is formed of a piece of wash-leather mounted on wood. Glass plates are also cleaned with a *buff*.

Cadmium — A scarce metal, found chiefly in the ores of zinc. The iodide and bromide of cadmium are extensively used in photography to form the sensitizing solution added to collodion.

Calotype — The name given to Mr. Talbot's process for producing negative pictures on paper by means of iodide of silver, developed with gallo-nitrate of silver.

Camera — A dark box of wood with leather or cloth sides fitted with a lens, opposite to which is placed the focussing screen, upon which the image formed by the lens is received. When a perfect image is apparent on the screen, the object is "focussed;" the screen is then removed, and the sensitive surface put in its place. There are many forms of camera adapted to various purposes.

Cap — The brass or pasteboard cover used to cover the lens of the camera while taking a picture.

Caseine — The cheesy portion of milk, which bears much resemblance to albumen. It is the active portion of whey or serum used in photography in the preparation of positive paper.

Foreign Correspondence.

Paris, January 10, 1859.

The interest excited by the researches of M. Nièpce de Saint Victor drew a very crowded audience at the *Académie* when M. Chevreul read the second part of the third *memoire* on the newly-discovered action of light. Whatever may be the estimation these researches are held in abroad (and I know that attempts have been made to decry their importance), here they excite a curiosity and interest second only to that caused by the daguerreotype itself. No one is better qualified to judge of their value, or estimate their importance, than M. Chevreul; and he has expressed himself honoured in being made the organ of communication by which they are given to the world,—and, further, he has himself read a communication supplementary to the researches of M. Nièpce, on "the influence of light on molecular action;" but more of this anon. I must now limit myself to an account of the further researches of M. Nièpce.

These later experiments were pursued with the same object as those last described. A sheet of Swedish filtering paper, sized only with starch, and then imbued with a weak solution of soda or potash, or of cyanide of potassium, and exposed to the sun's rays for about three hours, when treated with tincture of turmeric, yields an image which is yellow in the parts acted upon by the light, and red in the parts protected from its influence. When the paper is held to the fire, it is very rapidly carbonized in the solarized parts. Swedish filtering paper, if not sized with starch, does not produce the same effect.

A sheet of writing-paper sized with starch and exposed to the sun's rays for about three hours, reddens the blue tincture of litmus in the solarized parts, and the paper becomes *unsized*, or, at least, the sizing undergoes a change, for the paper is immediately permeated by water in the portions acted upon by the light; and this effect is more decided when the paper is imbued with soda or potash, or with iodide of potassium; but paper sized with gelatine is not *unsized* by the influence of light in the same time as a paper sized with starch.

Paper imbued with a neutral solution of nitrate of uranium is coloured a pinkish grey under the influence of light, and of a lighter or darker tone, according to the amount of humidity present. The image impressed on this paper will be of a very deep slate-colour if the paper has been imbued with the following solution:—Water 100 parts, nitrate of uranium 10 parts, nitrate of copper 5 parts; adding 2½ parts of yellow oxide of uranium to render the solution quite neutral. Lines traced with this mixture upon paper, and exposed while moist to the sun's rays, become coloured in a very short time; but it is remarkable that the colour disappears when the paper is put into a dark place, and is reproduced when brought again into the light,—and this change may be reproduced several times, till at length the paper ceases to change.

For the paper to become quickly coloured it must neither be too moist nor too dry, but slightly damp. Diffused light suffices to produce the colour quickly, and the longer the paper is exposed to it the deeper the colour becomes, and the longer it is in parting with it in the dark. If the paper is exposed too long to light it becomes permanently stained with a light greenish-yellow tint.

By means of paper imbued with starch, and afterwards submitted to the action of a concentrated solution of iodide of potassium, the action of a very feeble light is made evident. If a piece of this starched paper is submitted to the action of light for three hours, part of it being covered with an opaque body, then plunged into the indigo vat for about two minutes, and then put into water, upon being taken out, the paper, under the influence of the oxygen of the atmosphere, becomes coloured blue in the portion acted upon by light, while the other portion remains white!

Such are, by way of illustration, some of the curious results of the experiments carried on by M. Nièpce. They demonstrate — 1st. That in order for light to act upon organic or inorganic bodies, it is necessary that they be in a finely divided state, and in very thin layers — 2nd. That for the reduction and colouring of a metallic salt, it must be placed in contact with an organic substance, or of one of the three simple bodies—chlorine, iodine, or bromine—3rd. That the organic substance, after being submitted to the action of light, requires to be placed in contact with an inorganic substance.

M. Nièpce proposes to continue his experiments upon the vegetation and ripening of fruits, under the influence of the activity acquired by a solarized body. He has already obtained a result upon raisins contained in bags impregnated with tartaric acid. These researches are therefore not limited in their application to photography, but extend at once to dyeing and to horticulture.

By these researches I am reminded of M. Bayard, whose formula for a toning-bath I gave you in my last letter. M. Bayard is one of the creators of photography, and perhaps the most skilful we know in this marvellous art. Even before the publication of Mr. Talbot's processes, M. Bayard had himself discovered the means of fixing the images of the camera obscura; but by keeping the secret of his method he has missed the opportunity of obtaining universal renown. It is not generally known how he became one of the discoverers of photography; but as the fact is both curious and interesting, I may be permitted to relate it here.

M. Bayard is a clerk in the Treasury: he is the son of a justice of the peace, who resided in a small provincial town, and who occupied his leisure hours in cultivating a garden; his favourite fruit was peaches. It was his custom every year to send to his friends some specimens of this choice fruit, and naturally proud of his skill as an horticulturist, he sought for some distinguishing mark or sign by which his fruit should be recognised, and unwittingly he adopted a true photographic process. Selecting one of the finest peaches on a branch, to preserve it from the action of the sun, he enveloped it in leaves. When the peach, thus sheltered from light, had acquired the desired size, it was stripped of its covering, and freely exposed to the ripening and colouring influence of the sun. Only he first cut out in paper the initials of his name and glued them on to the peach. When, after the lapse of a few days, these paper initials were removed, the letters were found on the skin of the peach, of a brilliant white colour upon a red ground.

This phenomenon naturally attracted the attention of the younger Bayard, who amused himself with repeating the experiment in his own way, by employing rose-coloured paper, upon which he stuck various forms, such as crosses, &c. The parts of the paper protected by the superimposed figures retained their original rose-red colour, but the rest of the paper, when exposed to the sun's rays, became nearly white. Subsequently, when rumours of the wondrous achievements of Daguerre were spread abroad, he thought of using this rose-coloured paper as a sensitive surface for the camera, but of course without much success. His next step was to employ chloride of silver (the very agent now so generally employed); but the pictures he obtained in the camera were *positives.* His process consisted of exposing paper impregnated with chloride of silver to the action of light, but only to a certain degree, which experience had pointed out. When he desired to obtain a photographic picture he immersed this paper in a solution of iodide of potassium, and then exposed it to the action of light in the camera. The luminous rays had the effect of *bleaching*, or rather of rendering the salt of silver slightly yellow in the lights. The proofs were then fixed in hyposulphite of soda, and when exhibited at the Sorbonne, some twenty years ago, in fact before those of Mr. Talbot were made public, they astonished all who saw them. He sacrificed renown to the pleasure of keeping his secret.

But I must return from this episode to the researches of M. Nièpce, or rather to M. Chevreul's pendant to them. M. Chevreul, in his communication to the *Académie*, observes, that it is of the first importance to distinguish two conditions in the chemical action of light—one, in which, acting alone, it decomposes a body, or effects the combination of two bodies; and that in which it acts concurrently with a body upon a complex body. Various interesting experiments are given in elucidation of these conditions, which would occupy too much space if detailed in this place.

M. Chevreul further adds that the facts stated by M. Nièpce in his last memoir, are important, not only for their connection with our views of chemical phenomena produced by the action of light acting either alone or in conjunction, but also (and that is the novelty in these researches) its *action*, its *dynamic power*.

We are indebted to M. Nièpce for the knowledge that a large number of bodies are susceptible of acquiring, by solarization, the activity peculiar to light itself. Other phases of this inquiry remain, such as — 1st, to determine the activity possessed by a fixed inorganic body which undergoes no chemical action while it preserves its activity in the dark; and, 2nd, an activity resulting from a slow chemical action that light determines in solarized bodies, whether, these bodies being compound, this action exercises itself upon their elements, or whether these bodies undergo this action only in connection with the medium in which they are placed.

I must apologise for dwelling so long on these researches, but the vivid interest they have excited here leads me to hope that they will be no less interesting to you; in fact they have, for the present, thrown all other matters into the shade.

J. P.

HIGHLY ALBUMENISED PAPER.

To the Editor.

Dear Sir — Will you allow me to correct an error into which the writer of the article on "Photographic Papers," in the *Photographic Journal* of the 1st instant, has, doubtless unwittingly, fallen?

In his rather sweeping condemnation of "highly albumenised paper," he says, that "it is to be regarded with suspicion, as the *very high glaze is not due to pure albumen, but to an admixture or adulteration, either dextrine or gelatine;*" and that "the presence of the latter is to be recognised *by the chocolate colour of the proofs when removed from the pressure frame, and if the wet proofs are allowed to dry in contact, they adhere together and are spoiled.*"

Although it is possible that some makers may use an admixture of gelatine or dextrine, I have never found it necessary or advisable to do so to obtain the highest glaze.

I send you, herewith, some specimens of different kinds of (foreign) papers, albumenised with *pure white of egg*, and I think you will find the *glaze* to be as much as it is possible to desire. Moreover, prints on these papers will, for the most part, come out of the printing frame of a somewhat chocolate colour, and will, if dried in contact, adhere together, showing that these latter conditions do not necessarily prove the presence of gelatine.

One thing you will doubtless remark on seeing these papers together, viz. — the great difference that exists in the tint as well as the texture of the papers themselves, as although they are all prepared in the same way, the tints will vary from the comparatively rather *dingy* Canson (which by the way has lately fallen off very much in quality) to the brilliant *pearly* white of that marked "New French," a difference that must have considerable effect on the tone of the finished proof.

I am, yours, &c. JOHN A. SPENCER.

[The tints of the various sheets sent us are certainly very different, and that specially named is very pleasing. Personally, we are not fond of highly-glazed paper, except for stereoscopic proofs, but that is rather a matter of taste. The article was written by a practised manipulator in printing photographic proofs. We are, however, obliged for Mr. Spenser's kind attention in pointing out the fallacy of the test relied on.—Ed.]

RESTRICTION UPON WORKS FOR EXHIBITION.

To the Editor.

Dear Sir—In the letter I wrote to you as published in your last *Journal*, you misconstrued my expressions, as if I had found fault with the council of the Photographic Society. I meant no such thing. I only told you how the resolution named affected me for the moment.

It is an open question, considering the increase in the number of manipulators, whether that measure, or throwing a greater amount of responsibility on the Hanging Committee, as to their judicious selection or rejection of works sent in, is best.

I will in another letter put down my opinion how this *open question* might possibly be practicably settled.—I am, yours, &c.

O. G. REJLANDER.

[We are sure that Mr. Rejlander's remarks, as published in our last, cannot be regarded as in any way offensive to the council of the Photographic Society, composed as it is of gentlemen whose desire to promote the welfare of photographers and the art they practice is unquestionable. We are convinced, on the contrary, that they are glad to have an opportunity of ascertaining how such a regulation affects those in Mr. Rejlander's position.—Ed.]

INK PRINTING PROCESSES.

To the Editor.

Sir—Permit me to congratulate you on the improved size and *general character* of your *Journal*. There is something in it which, in my judgment, commends it so much to the practical photographer, that I doubt not the number of your readers will soon be multiplied three-fold.

I was much amused with your remarks respecting the cool manner in which a M. Asser puts forth in the *Cosmos*, as *new*, the ink printing process mentioned by McCraw, which, you say, truly enough, is only a modification of that of M. Sella, which, further, allow me to add, is almost a verbatim description of a process discovered by Mr. Perry, and which, through me, was patented some twelve months *before* ever this Piedmont gentleman had written a line on the subject; so, that in fact, neither M. Sella nor Mr. McCraw has any more just claim to the *discovery* than M. Asser.

Before closing, I may further state, that Mr. Perry and myself, having tried various salts of iron and other metals in a thousand different ways upon plain, gelatinized, albumenized, and other papers, have come to the conclusion that the best picture is produced by first printing simply with the chromic salt, then treating the picture with the iron, and lastly, with the gallic or the pyrogallic in conjunction with acetic acid. In order, however, to preserve the purity of the whites, great care should be taken to wash well between each of the processes.—I am, yours, &c.

28, *Old Bond Street, London, Jan.* 6, 1859. T. SHARP.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

To the Editor.

Dear Sir—A slight error has occurred in the report of our November meeting, which please correct.

I allude to the remarks made by Mr. Johnstone, which should read—"I believe I was the first who suggested the crayon principle to the Rev. T. Meyler [not *Mayall* as reported] in 1851, which was successfully carried out by Mr. Mayall, in his patent revolving disc. Your insertion of the above will oblige, yours respectfully,

Jan. 4th, 1859. C. S. HAINES, *Hon. Sec.*

DEVELOPEMENT AFTER FIXING.

To the Editor.

Sir—I send you a few lines on the developement of collodio-albumen pictures *after* having dissolved out the iodide of silver in the fixing bath. I was induced to try the experiment, from having often re-developed pictures that were too weak after they had been fixed in the hyposulphite of soda solution; I therefore took a sensitive collodio-albumen plate, and exposed it in the printing frame for the usual time, then placed it in solution of hyposulphite of soda until all traces of the iodide of silver were removed from the plate. Having washed it well under a stream of water, and developed in the usual manner, the result was a good picture but of a *red colour*.

I find that they will develope quite as well in the dark room, and also that they will keep for days exposed to daylight, without altering the effect.

I have also tried the same process, using cyanide of potassium (one and a half grains per ounce of water) instead of hyposulphite of soda, and got a good picture with much better tone; but in the latter case it requires rather longer exposure, or will take a long time to develope.

With regard to the objectionable tone of the pictures after being in the hyposulphite of soda, I was speaking of it to a friend of mine, Mr. Parry, an old and able photographer, and he suggested toning with chloride of gold. I did so, and the result was a picture with a beautiful purple tint. I have sent you three prints developed as above.

No. 1, developed after fixing with hyposulphite of soda.
No. 2, " " " cyanide of potassium.
No. 3, half-toned in the chloride of gold bath.

I am, yours, &c. J. H. YOUNG.

[The proofs received fully bear out the statements made, being quite distinct and sufficiently dense. We have little doubt that a very important principle in the practice of photography, upon dry plates, is here opened up. We shall certainly recur to this subject again.—Ed.]

TO OUR AGENTS AND ADVERTISERS.

It is announced in another column, that with our next publication will be tried the interesting experiment whether or not photogalvanography be suitable for the economical illustration of books, &c. With the "Journal" of the 1st February will be PRESENTED to our Readers, a picture worked on stone, from a plate prepared by Herr Paul Pretsch's patent. As there will doubtless be a vastly increased circulation on that date, our Agents will oblige the Publisher by forwarding an EARLY intimation of the number they require. Advertisements should also reach the Publisher not later than the 25th of the present month.

*** *As additional Agents are required for the Sale of this Journal in all localities where none have yet been appointed, the Publisher will be glad to receive applications from suitable persons, addressed to him at* 32, Castle Street, Liverpool. *Beside the Wholesale and other Agents for the Journal already in the Metropolis, the Publisher is desirous of appointing other Sub-agents in London and its suburbs.*

ANSWERS TO CORRESPONDENTS.

J. B., Darlington, is thanked for his suggestions.

James Braby—Messrs. Smith, Beck & Beck, 6, Coleman Street, City, will supply you with the article you require.

P. S. D.—Hyposulphite of soda must be employed for clearing Fothergill's plates, as well as those by Taupenot's process. If you use cyanide of potassium you will certainly spoil your negatives.

Quasimodo—If you get Hardwich's "Photographic Chemistry" (Churchill), you will find all you require. We advise you to wait a few weeks, as we know that a *fifth* edition will be out very shortly.

T. B.—We have not seen the arrangement for stereoscopic pictures, described in a recent number, as having been exhibited at the Photographic Society of Scotland.

Nil Desperandum, &c.—The rest of your signature is too complimentary for insertion. We think *both* processes would yield good results, and any good collodion is suitable. We will endeavour to attend to your third query in our next.

Twaddle—We cannot help what other persons allege as stated by us. We refer you to our own pages for our own assertions, and if others will misquote us, either by accident or design, we cannot be held responsible. We never made the statement you mention.

Stereo—We have long since abstained from noticing rude and foolish statements in the publication you name, and do not intend to treat the present one in a different manner. If you will refer to our article on the subject, you will find our contemporary has made either an *absurd mistake* or a *wilful misstatement*.

Juvenile is surely joking when he recommends brimstone and treacle, with acetic acid, as a *new dry process*—at least, we should have thought so, only those who intend practical jokes do not usually send their real name and address as our correspondent has done. It is true, that in the formula he gives, the brimstone is filtered out; but to what end is it first added? The mixture, when made, is but a very inferior kind of oxymel, and nothing whatever new in principle is introduced. We strongly advise all who wish for good pictures to *avoid* the brimstone, at least.

Spectemur Agendo—Without any question the *last*-named of the three producers which you mention is the one you should apply to; moreover, he constructs them for the purpose you require *specially*, and *not* to be used for the other one, for which you are already supplied. The pin-hole blisters would probably be avoided in the collodio-albumen process, by letting the collodion *set well* before sensitizing, and also drying the albumen perfectly *by heat*, before the final immersion in the bath of aceto-nitrate of silver.

John Simpson will find the information he desires relative to colouring glass positives in our last volume, pages 193, 206. See also a pamphlet by A. N. Rintoul on this subject, and a chapter on the same in the "Photographic Teacher," by G. W. Simpson.

Received—A. R., Glasgow.

Erratum—There was a typographical error in Mr. Hardwich's paper "*On Gold Toning on Albumenized Paper*" in our last number. The chloride of gold solution should contain one grain per *drachm* of water, instead of per *ounce*, as printed.

☞ *To meet the pressure on our space, owing to the numerous reports of meetings, a large temporary increase of pages has been made in this number of the* Journal—*notwithstanding which, several interesting articles in type are left over, including the conclusion of the Editor's paper on* Suggestions for the Improvement of Landscape Photography, &c.

THE PHOTOGRAPHIC JOURNAL.

No. 87, Vol. VI. — FEBRUARY 1, 1859.

As indicated in our last, we have now put to the test of actual practice the suggestion thrown out by Herr Pretsch, relative to book-illustration by the assistance of photography; and though the present is the first attempt to produce any very large number of copies from a single original negative, we have undeniable evidence not only of its feasibility, but of its practical utility and economy, and are prepared to show that there is no reason whatever why *a hundred thousand copies*, or more, of good serviceable illustrations may not be thus produced from one photograph.

When we made the promise of presenting with each copy of the present number a specimen, provided the experiment should turn out successfully, we did so under the impression, that with Herr Pretsch's permission and promised assistance, every impediment to our performance of it was removed; but within the last few days we have received an intimation from the Hon. Henry Fox Talbot, that by carrying out our expressed intention we should, without first obtaining his sanction, be infringing a patent granted to him in 1852. We are of course not in a position to decide upon the validity or otherwise of patent rights, nor do we know in what particular manner the alleged infringement would occur; but it would ill become us, even if we had the inclination, to contest the point with a gentleman to whom we, in common with all photographers, owe a deep debt of gratitude; we have therefore sought for this gentleman's sanction to our issuing the proofs we have prepared, and this permission he has liberally accorded, consequently our readers have before them the means of judging how far the attempt has been successful, to place within their reach a method of cheaply and economically producing a very considerable number of illustrations, available for commercial or other purposes.

Before giving, as we intend to do, a short descriptive outline of the various steps in the production of the finished lithograph, as now presented, we desire to make a few preliminary observations, in order to avoid any misapprehension as to the object in view. It is not intended to supersede the present method of photographic printing in any of its forms; it is not regarded as of any aid to photography, but on the contrary, as *borrowing from photography* a certain amount of assistance which enables any person to procure for circulation or illustration very many copies of any object whatever: this is the point in which *photographers* are interested, as there is not one amongst us who may not possibly hereafter be called upon to play his part in the operation. But as it is not for the purpose of producing *photographs* that our labours are directed, we get what assistance we can from photography, and obtain the rest of our requirements by any other means at our disposal, the two main features being to acquire a certain something at the least possible cost.

It is in consequence of a remark recently made by our able predecessor in the editorial office, Mr. Malone, at one of the meetings of the Photographic Society, that we have been induced to follow out thus far Herr Pretsch's suggestion, which we now more particularly explain.

A negative was taken upon collodion in the ordinary way by Mr. Fenton, from this a transparent positive upon paper was produced by direct contact. With the transparent positive an impression in relief upon a mixture of gelatine and bichromate of potash was obtained by the agency of light; from this a mould in some plastic material, upon which copper was deposited by means of the electrotype process, and thus a copper *matrix* was produced, capable of affording, by subsequent assistance from the electrotype process, a number of copperplates more or less fit for printing with in the ordinary manner of using copperplates for this purpose. All this has been already explained at length in our last, and also in some previous numbers of this *Journal.*

At this stage an option is presented to the operator: he can either make any desired additions or corrections to his plate by calling in the services of a copperplate engraver, or delay the "touching" till a subsequent period. Should the number of impressions desired be very large, it is perhaps, most economical to correct the plate itself, but if comparatively few, then the amendments are better delayed. In the sample before us, the corrections were made on the copperplate.

An impression was next taken in the copperplate press — but instead of its being upon ordinary paper, it was upon that kind employed by lithographers to receive the writing or drawing intended to be transferred to stone, and the transfer was effected in the ordinary manner employed in lithography, the marginal lines and lettering being subsequently added.

Any desired "touching" can be now added instead of performing the operation upon the plate, and as the requisite skill is more easily acquired for "touching" lithographs than copperplates, it is of course less costly; but on the other hand, if it be done upon the plate, we are enabled to prepare a large number of stones to print from simultaneously, (with only once doing the work of correction), where it is advisable to work off many impressions, especially if they are required in a short space of time.

Such is the method by which the print now before our readers has been produced; and we cannot but think that Herr Pretsch has placed before the public a most important means of economical illustration. Amongst other applications of it, how cheaply and rapidly could books of manufacturers' patterns be got up, with a fidelity that would render them invaluable, in many cases obviating the necessity for the carriage of bulky samples, and in others affording all the advantages of the exhibition of samples, when from the nature of the goods such actual exhibition is altogether impossible. In the first category we may place articles of hardware, glass, ceramic manufactures, and such like; in the second — stoves, grates, furniture, &c., &c. Again, patterns of valuable lace, &c., could be multiplied at a trifling cost, and transmitted in all directions by post.

Should the public take up this matter, we have no doubt that any trifling difficulties as regards patent rights will be most easily got over.

In conclusion, we give a letter from Herr Pretsch, affording some further interesting particulars, in reply to some queries of ours.

162, *Great Portland Street, W.*

My Dear Sir, *January 22nd*, 1859.

The original of the plate which you are going to publish, I still keep in my hands; it is an ordinary positive on paper, not too thick. Real transmitted positives on glass answer far better, especially if they be taken from larger negatives on glass. A soft tint over the

original, with not too much contrast between light and shade — not too white and black — produces brilliant pictures. However, in many instances I have also obtained brilliant plates, leaving nothing to be desired, from some French positives on paper, bought in some of the shops in London. They have been mounted. I took them off from the stout paper carefully, and made them a little more transparent by means of diluted Canada Balsam, that is all.

I am convinced, that although my process yields at present very nice results, nevertheless a great deal more can be done by it — things which are not dreamed of now.

Concerning the touching up of a transfer on the stone itself, it might require a man possessing technical experience, artistic feeling, and good will, but I am sure it can be done. Believe me to be, dear Sir,

Yours faithfully, PAUL PRETSCH.

The Council of the Photographic Society held a soirée at the Exhibition Room in the Gallery of British Artists, Suffolk Street, Pall Mall, on the 20th ult., at which a large number of members of the society and visitors, including many of note in the scientific world, were present. The gathering was also graced by the presence of a considerable number of ladies; and judging from the animated conversation which was everywhere carried on over the numerous specimens exhibited, the photographic art appears to gain increasing favour with the fairer sex.

We were happy to notice, that the president of the society, Sir Frederick Pollock, was able to do the honors upon the occasion, which we had feared, from his recent indisposition, would have been too severe a tax upon his energies.

It is with much pleasure that we have to record the more intimate union of the principal photographers of Liverpool than was possible while simply forming a portion of the Historic Society of Lancashire and Cheshire. By the latter connection, the scientific part of their progress is duly cared for; but photographers are but men, and they require something besides this—they require a more informal and unrestrained intercourse, for the purpose of a friendly interchange of ideas upon little matters of detail, that are insufficient of themselves to be discussed in a scientific assembly, yet go far to make up the experience and knowledge essential to constitute a skilful manipulator. To meet these desiderata, the principal men amongst those practising our art in Liverpool and the neighbourhood, have formed themselves into a friendly club, meeting periodically to discuss the points of immediate interest over a cheering cup of tea. We have no doubt that this is a move in the right direction, for "out of the abundance of the heart the mouth speaketh." It is therefore not only calculated to further the interests purely photographic, but what is of quite as much importance, to engender a feeling of sympathy and kindness, that we have always found conducive to progress. We most heartily wish them success.

[Mr. Greenwood, like any other correspondent, conceiving that he has been attacked without just cause, demands space for the following reply.

We regret the introduction of any personal matter into our columns at all; but as the letter is explanatory of matters that materially concerns our readers, we feel bound to admit it.—Ed.]

Dr. DIAMOND and "Mr. GREENWOOD."

As Dr. Diamond, the editor of the *Journal of the Photographic Society*, has thought fit to introduce my name into a misleading and disingenuous paragraph with respect to this *Journal*, in his publication of the 21st January, I think it courteous and due to my supporters to explain certain circumstances connected with the recent alterations, and then leave my readers to draw their own conclusions.

For a considerable time past I have had numerous hints from friends having business relations with this *Journal*, that the omission of the local prefix, "Liverpool and Manchester," in the title would be beneficial, on the ground that those words in appearance (though not in *reality*, as was shown by the suggestions coming from places very wide apart) implied local restriction, and thus were calculated to be injurious to the interests of the *Journal*—while I, as proprietor, felt ambitious of representing photographic art throughout the world, without being confined to the specified localities named in the title, or indeed to any others.

These friendly hints (often received) remained for a considerable period unheeded. The intimate and cherished relations which this *Journal* has for so many years maintained with the early and earnest photographic workers in Liverpool and at Manchester—the many acts of kindness experienced, both personally and in connection with the *Journal*, from my friends in this town and the neighbouring city—naturally made me unwilling to sever the friendly ties which bound my publication to its earliest and warmest supporters.

However, during the past year, this *Journal* became the official organ of Societies in other localities. Its columns became filled with matter from the new as well as from the old world—the artists of Australia as well as those on the Continent of Europe became more interested in its contents—and even India became a claimant for its share of representation. I therefore thought it an imperative duty to myself and to my supporters to sink the local in a more general name—or, to speak more strictly, to change the position of the local designation, and to carry it, with additions, below, instead of leaving it above, the general title,—thus securing three objects:—

1. The retention, intact, of the leading line of the former title — the words "PHOTOGRAPHIC JOURNAL."

2. The assertion of the fact of its *universal* representation of the photographic art.

3. With the two former objects attaining the no less pleasant and useful one of preserving my friendly connections with Liverpool and Manchester, and fully meeting the requirements of business correspondents.

Having arranged matters thus far to my satisfaction, I next, like an honest, unsuspecting, business man, announced the contemplated change of title, size, and editorial arrangements, in my own *Journal*, in the *Journal of the Photographic Society*, in the *Athenæum*, and elsewhere, some time prior to the change taking place — never suspecting that aught but what was straightforward and upright was involved in the announcement. But, lo! a few days before the first publication of the altered *Journal*, and when the number was far advanced in arrangement, Dr. Diamond registered *a* Journal under the title of the *Photographic Journal* — thus attempting to "filch from me my good name." No time was lost in ascertaining whether the steps I had taken were *legally* and *morally* right. The "opinion" of an eminent special pleader, in reply to the "case" laid before him, fully justified every step. I felt bound to keep faith with the readers of my *Journal*, and I brought it out with the previously-announced title of *The Photographic Journal* — which I had, as I was advised, a perfect right to assume.

Then followed a letter, signed "Parke and Pollock," threatening me with an application for an injunction if a second number should appear with the title objected to; which letter I handed over to my solicitor, instructing him to take the necessary steps if the threatened application were made.

This document was followed by the "special pleading" of Dr. Diamond in his *Journal* of the 8th January, in which he laboured to attach blame to me for assuming my title, a title which I felt I had an indefeasible right to use. In the "shorthand of the trade," Dr. Diamond said, the Society's *Journal* was known as the *Photographic Journal*, &c., &c., &c. I have had a tolerably extensive and increasing correspondence for some years, in connection with this publication, in which allusions to all existing Journals have frequently occurred; but never, to my recollection, except in one instance, was the *Journal of the Photographic*

Society ever styled the *Photographic Journal* in all this correspondence. The "London Journal" and the "Society's Journal" were the appellatives used, where other than the correct title was introduced. It may be, I grant, that correspondents (who are not usually precise, or do not care to be technically correct), in addressing the Editor or Publishers of the *Journal of the Photographic Society*, have frequently addressed letters as to the *Photographic Journal;* but so they have, in innumerable instances, to this *Journal.* I would not, however, be so unreasonable as to ground an arbitrary *right* to a title on such mere conventional terms. If Dr. Diamond, his predecessors, or the Council felt they had an exclusive right to the title, why did they not take it long before my announcement, instead of appearing before the world for so long a time as the mere organ of the Photographic Society? Why solicit advertisements by notes, headed "*Journal of the Photographic Society*," as received by myself? What means had I of knowing, prior to the recent allegation made by Dr. Diamond, that the Society's publication was known as the *Photographic Journal?* Certainly, it must have been by intuition, if at all, seeing that the title plainly printed on the cover, at the head of every page, and on its circulars, was—the *Journal of the Photographic Society.* I may add, also, that I could not discover any thing to the contrary in the publication itself, in its announcements, or in the recent determination of its conductors, accompanied by threats, carefully to prevent the papers read at the meetings of the Photographic Society appearing elsewhere till they had been published in the columns of the Society's *Journal*,—on the plea that they, as well as the *Journal*, are the property of the Society. Notwithstanding Dr. Diamond's assertion to the contrary, I believe it has rarely, if ever, been quoted other than the *Journal of the Photographic Society.* I certainly have never seen it otherwise quoted, although my long connection with the newspaper press has given me ample opportunity of so doing, had it been so. Indeed, excepting in the foreign Photographic Journals (which are largely made up of matter from their English contemporaries — my own being extensively used), I have rarely seen it quoted at all. A few weeks since, in one of the French Journals, the old and full title was given in connection with an extract from the former.

The very arguments Dr. Diamond recently put forth to restrain a contemporary from anticipating the Society's organ in the publication if its reports, showed, as plainly as an intelligent writer could put it, that publication to be closely bound up with the Society, or the Society with it (which is about the same thing), not only in its position as the Photographic Society's organ but as its property.

With respect to another notable argument, by which Dr. Diamond labours to sustain his case, viz., that the *Journal* account was kept under the designation of the *Photographic Journal*, I must plead ignorance of that fact, — not having had the privilege of looking into his publishers' ledger, to see how the account had been kept; but all good book-keepers, it is to be presumed, would lessen their labours by using a short designation instead of a very lengthy one. Perhaps, too, the publishers' ledger is of rather portly dimensions, and of ancient date, and the account may have been opened in the infancy of the photographic art, ere the *Liverpool Journal* had started on its successful career, and when the Society's Journal was in reality the only one in existence.

The "shorthand of the trade!"

It is the *long* hand of common sense and common fairness that I wish to be guided by in my business, and by the latter I was guided when I announced the *modification* of the old title.

Dr. Diamond has the interests of the Society's property to look after!

Well! I have my *own* interests to guard; and I *personally*—and not a wealthy Society — should have to bear the consequences if my *Journal* property were ruined by uncalled-for changes. My own experience, gained by years of toil, anxiety, and care, in building up the fortunes of this *Journal*, prompted me to make as little alteration in the title as was absolutely necessary.

I have also had to bear and will "*for the present*" have to bear, the consequences of the confusion caused by Dr. Diamond having — in a moment of unreason — rushed to Stationer's Hall, and registered *a* something under what is *my* unquestionable title. *I* have also received a communication from the Postmaster-General respecting the "confusion" caused by the contested title of the *Journals;* but I think my explanation showed pretty plainly that the "confusion" was *not caused by me.*

I will close these lengthy remarks — called forth by Dr. Diamond's allusion by *name* to me, in his issue of the 21st January — by further stating that while my publication of the 15th January was in course of being printed off, I received another missive, signed "Parke and Pollock," threatening that if a second number of *The Photographic Journal* should appear with that title they would —— what?—apply for an injunction to restrain me from using it! What new circumstances called for this second "paper pellet?" I beg to assure Dr. Diamond and the Council of the Photographic Society, that my career in life has been so little litigious I did not require to have a legal threat sent me in duplicate to keep me in remembrance of my position:—however, the latter letter has passed as quietly as the former into the safe-keeping of my solicitor, to whom I have requested all future communications from the same quarter to be addressed.

In conclusion, I have to state thus publicly, that while I exceedingly regret the collision between the Council of the Photographic Society (which body I willingly admit has done much for the advance of photography) and myself, caused, I believe, by Dr. Diamond's precipitancy and vain fears for his *Journal*, I am much better prepared to defend my right to the title of *The Photographic Journal* than I think Dr. Diamond can be in defending his own conduct in endeavouring, by his questionable proceeding, to circumvent me in carrying into effect my publicly-announced change in the title of this *Journal.* With care, attention, energy, and an intelligent application of capital to all its departments, including the acquisition of the best obtainable editorial talent, together with that of able coadjutors, it shall not be my fault if the *old* "Liverpool and Manchester Photographic Journal" do not become THE *Photographic Journal* of the Country!

HENRY GREENWOOD,
PROPRIETOR OF "THE PHOTOGRAPHIC JOURNAL."

ON THE DELINEATION OF MICROSCOPIC OBJECTS BY PHOTOGRAPHY WITH ARTIFICIAL LIGHT.

By M. S. Legg.

(Read before the North London Photographic Association, 27th Jan. 1859.)

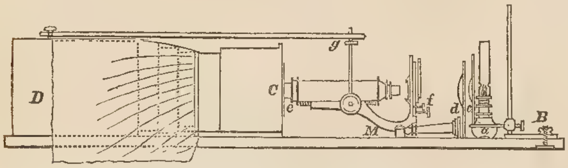
At this season of the year when out-door photography is for the time suspended, I have been endeavouring to carry out the principles laid down by Mr. Delves and others, in combining the microscope and the camera, with a view to obtaining enlarged representations of minute objects; and, as a *demonstration* of my mode of operation may be interesting to the members of this Society, I am induced to bring before you my apparatus, which, although homely, has enabled me to produce pictures which give promise of future success.

As a foundation I have a plank of deal, eleven inches wide and five feet in length, upon which are fixed along a central line various means of securing the several parts always in the same position, so that on commencing operations but little time is lost in adjusting, &c.

The source of light (a small camphine lamp, *a*) is placed in the ring of a retort stand, *B*, which stand is secured by a nut and screw to the board.

The rays of light are condensed and rendered parallel by means of two bull's-eye lenses, one about two inches diameter, *c*, brought almost close to the lamp, and the other about three inches diameter, *a*, within an inch of the first. The amount of light obtained by this means enables me to take pictures with the 2-3rd and 4-10th

powers at a distance of three feet from the object glass to the sensitive plate, and I have not yet obtained any advantage by attempting to concentrate the rays upon the object by further appliances. I am therefore inclined to think that success much depends upon having parallel rays, and the amount of light is quite sufficient for moderate powers.



The microscope (one of Smith and Beck's, M) is furnished with a tripod foot, which, in this arrangement, I remove—I also dispense with the bar carrying the mirror—it is then placed as it were on its back, and secured by a notch on the board, the body being in a horizontal position, and at a sufficient height to correspond to the front of the camera—the eye-piece is taken out, and the compound body slipped on to a tube, *e*, fitted to the sliding front of the camera, *C*—this tube is lined with black velvet to prevent reflection of the rays passing from the object-glass.

The camera is kept in its place by a slip of wood screwed to the board on each side, so that its motion is confined laterally, but it tranverses quite freely lengthwise.

The apparatus being thus arranged, I am enabled to use the stage adjustments, *f*, and focus the object on the ground-glass screen without difficulty, but the field of view is limited to about two and a-half inches diameter. I have therefore allowed the rays of light to pass on through the front of a second camera, *D*, in order to obtain a flat picture of four inches diameter, extraneous light being cut off by means of a black cloth; but here a difficulty arises in focussing at this greater distance, it being impossible to see the focussing screen and adjust at the same time. This however, is obviated, by adapting a kind of crank and lever movement, *g*, attached to the milled head screw, and passing over the top of the cameras, thus giving the focus with the greatest nicety.

The above description is that of my own apparatus, in which I have adapted to each other such parts as are used for other and separate purposes; but whatever be the make of microscope or form of camera, the principle is the same—which is, to adapt each part to the *axis of the microscope*, to employ as nearly as possible *parallel rays of light*, and, if desired, to obtain a large field, *to extend the rays* to a distance of three or even four feet before reaching the focussing screen; indeed, I see no reason, by employing the sun's light, why the rays may not be extended to any reasonable distance, by using a long camera and lengthening the focussing rod.

The object glasses I employ are (like the microscope) those made by Smith and Beck. Until lately, I have acted upon the experience of our worthy vice-president, in adjusting for the difference of the chemical and visual foci, and which I quote from *Hardwich's Photographic Chemistry*:—"An inch and a-half objective of Smith and Beck's make required to be shifted 1-50th of an inch, or two turns of *their* fine adjustment; a 2-3rds of an inch, 1-200th of an inch, or half a turn; and a 4-10ths of an inch, 1-1000th of an inch, or about two divisions of the adjustment. With the 1-4th and higher powers, the difference between the foci was so small as to be practically unimportant;" but I have lately had added to each of my 1-100th and two and three inch objectives, a lens of low power, which effectually corrects the focus without any further adjustment.

In regard to objects upon which to experiment, I find those possessing but little colour the best, those having any amount of red or yellow stopping the actinic rays and affording scarcely any detail. This point, however, is one of which I hope to speak more confidently at a future period.

Having thus described the mechanical and optical arrangements of my method, I will just observe, that in taking the pictures I use ordinary negative collodion; sensitise in a slightly acid bath, and develope first of all with iron solution, which brings out the picture with all its details in one or two minutes, and then (if it appear satisfactory) intensify with pyrogallic acid. This latter part of the process is rather tedious, occupying from fifteen minutes to half an hour. The time of exposure of the plate varies from three to ten minutes; if the object be very transparent, like the spicula of sponge or Gorgonia, three minutes will suffice; for vegetable tissues, four or five minutes; and for parts of insects, having a certain amount of colour, ten minutes will sometimes be found necessary.

SUGGESTIONS FOR THE IMPROVEMENT OF LANDSCAPE PHOTOGRAPHY, WITH HINTS FOR THE ENLARGEMENT OF NEGATIVES.

By the Editor.

[*Concluded from page* 318 *of the Liverpool and Manchester Photographic Journal.*]

For certain reasons which I shall give presently, it will be best to employ the smaller of the two surfaces as the curved one; one of them being, that by so doing, an advantage is gained in superior definition at the edges if the negative be taken direct upon it. There would be no difficulty in procuring the necessary curves, by employing a set of watch glasses, all cut from the same or similar sized globes of glass, and that which presents itself at once to the mind of a photographer, viz., the coating with an even film of collodion is altogether imaginary, as I am assured by Mr. Skaife, of Blackheath, who kindly showed me some that he had done, and which were most perfectly and evenly coated, as he stated, in precisely the same manner as flat plates.

Assuming, then, that we set out by taking small sized negatives upon concave surfaces, the next consideration we have to decide upon, is the form of lens best adapted to effect the requisite enlargement.

It is not necessary in this part of the process that the lens should include any large angle of vision, because we can regulate the distances of the object and sensitive film from the lens relatively, so as to meet the requirements to ensure the desired degree of amplification. The larger the diameter of the lens, however, for any given focus, provided it be properly corrected, the more rapid will its action become: and this quality is of some importance, as the amount of exposure required for an enlarged picture is as the square of its linear increases in size.

To any one, who like myself, has been for many years devoted to microscopical investigations, coupled with a particular love for optical science, it appears truly absurd to suppose that any insuperable difficulty should exist in producing a compound lens, capable of rendering the most minute details of any photograph with the utmost delicacy and fidelity.

If we employ a negative upon a concave surface, a well-made portrait combination ought to give a fair result, provided the enlargement be but moderate—say not exceeding four or five diameters; but if we desire to increase the size in a much larger ratio, I cannot but imagine that a compound lens, constructed upon the same principle as that employed by the best makers for the production of *microscopic objectives*, of low power, might be most advantageously resorted to; and as the relative proportions of curvature for all the surfaces of the various component parts, compared with the refractive and dispersive powers of the kinds of glass employed, are already known, no further calculation, beyond a simple multiplication of the length of radii, and distances of the component parts would be necessary. The peculiar properties of the compound lens to which I allude, were discovered by Mr. Joseph Jackson Lister, F.R.S., some five-and-twenty years ago, and then described in a paper read before the Royal Society; but it is only within the last two years that some of the most valuable qualities have been developed in practice, though well known and remarked upon theoretically by Mr. Lister at the earlier period.

It may not be uninteresting to indicate, in few words, the principle upon which these lenses are constructed.

Mr. Lister found, by direct experiment, that an achromatized plano-convex lens possesses two points in the anterior focus, from which images formed in the conjugate foci become *perfectly corrected*, while, from any other points, they are only approximately so. Moreover, if a point be selected *between* those producing perfect images, the error remaining is found to be in an *opposite* direction to that arising when the point selected is either nearer to, or farther from the lens than the two perfect points.

He, consequently concluded, that by judiciously combining a pair of achromatized lenses, at such a distance apart, that a ray proceeding from the nearer perfect focus of the front lens, and transmitted to the second, in a direction *as if proceeding from its more distant* perfect focus, any deviation in position of the object examined would cause an error in one direction by the first lens, that would be exactly counterbalanced by an equal one in a contrary direction, produced by the second combination, and thus a constant equilibrium obtained.

On trial this theory was found to be correct, and I cannot perceive any reason why we should not avail ourselves of it for the purpose at present under consideration.

It is highly probable, also, that the peculiar combination recently introduced for photographic purposes, by Professor Petzval, if reversed in position, might be found admirably adapted for enlargement, and I am strongly of opinion that this would be the case.

Let us now proceed to the practical application of the principles we have been endeavouring to establish.

We first adapt our dark slides to receive circular concave glasses, of about two-and-a-half inches in diameter, and have a similar one, previously lightly ground on the concave side, mounted as a focussing screen.

Instead of grinding, we may coat it with collodion, sensitise, wash and dry it, in which condition it will answer admirably for focussing upon.

Having prepared the necessary chemicals, we coat our glasses, sensitise in the ordinary way, expose for a fraction of a second of time, and develope at once. The collodion film may be thin and the negative very weak, provided that the details are all obtained. On no account must the developement be pushed too far, as the subsequent operations afford us every opportunity of increasing, to any desirable extent, the contrasts between the lights and shadows of the picture. Perfection of detail and *absence of density* is what we aim at.

If we content ourselves with one uniform extent of enlargement in all cases (say five diameters), our subsequent operations are very simple: in this case we should have a camera some seven or eight times the focal length of the lens employed (which we will suppose to be of about eight inches from the optical centre), consequently about six feet in focal length, and of dimensions sufficient to receive a plate ten inches by eight. At one end a groove is made to receive the usual dark slide. The whole should be lined with black cotton velvet, and a division inserted at about one foot from the end to receive the lens. A frame to hold the negatives should be adapted to the end nearest the lens, and be capable of adjustment nearer to or further from it; which adjustment should allow of being performed from the opposite end of the camera, a matter of but trifling difficulty. A negative, with the collodion side towards the lens should then be placed *in situ*, and being turned towards the sky, is to be very accurately and carefully focussed, by aid of one of Ramsden's eye-pieces (described by me in a recent number of the *Liverpool and Manchester Photographic Journal)*, when the whole will be ready for taking the enlarged picture, which is done in precisely the same manner as an ordinary picture is taken, the exposure required being, however, 5 times 5=25 times longer than that necessary for a picture of the same size as the original. The result will be a *transmitted positive*, which, although it may be allowed to exceed the original in density, should be rather full of detail than particularly intense.

From this transmitted positive thus obtained, *a number of negatives* (a point of considerable importance, where many proofs are required in a limited time) may be produced by any of the dry processes, the plates being brought into *actual contact*, to which end perfectly flat pieces of plate glass should be made use of, and these negatives can be used for producing prints upon paper.

It is because the two last operations are to be performed by actual contact, viz., the production of the enlarged negative, and also the printing, that the smaller of the two surfaces was that selected from the curved one.

From such experiments as I have been able to perform in reference to this subject, I am perfectly satisfied, that with a very moderate amount of patience and perseverance, some admirable results may be obtained; and it is a source of considerable regret to me, that my constant occupations, either in business matters, or in conducting *The Photographic Journal*, precludes the possibility of my devoting sufficient time to the carrying out to perfect fruition the ideas I have had the honour of laying before you.

It is, however, with a hope that some of my Liverpool friends, whose energy and perseverance in the cause of photography are well known to me, may be induced to devote some attention to a course, in which I am convinced that good fruit is to be found, that I have selected the subject I have brought under your notice, and I thank you heartily for the kind feeling which induced you to call upon me to do so.

NITRATE OF SILVER BATH FOR POSITIVE PRINTING.

The sensitising bath, upon which albumenised paper is floated, sometimes acquires a deep colour, which may be removed by kaolin, pipe-clay, or fuller's earth; but a readier mode is to add to the bath eight or ten drops of a solution of chloride of sodium, of the strength of twenty grains to the ounce of water, and shake it it violently immediately before any precipitate is formed, and repeat the operation a second and a third time, if it be required. The solution allowed to subside becomes quite limpid. About thirty minims of the salt solution is sufficient for twelve ounces of silver bath.

A CONTRIVANCE FOR INSTANTANEOUSLY VARYING THE SIZE OF ORIFICE, BETWEEN THE LENSES OF A PORTRAIT COMBINATION WHILST WORKING.

FIG. 1.

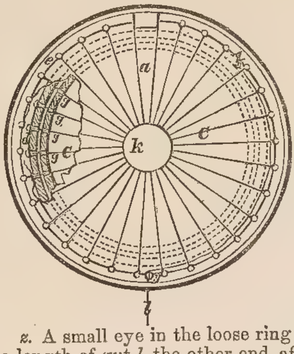


Figure 1 is a front elevation, and figure 2 a longitudinal section of the diaphragm placed in the lens mount.

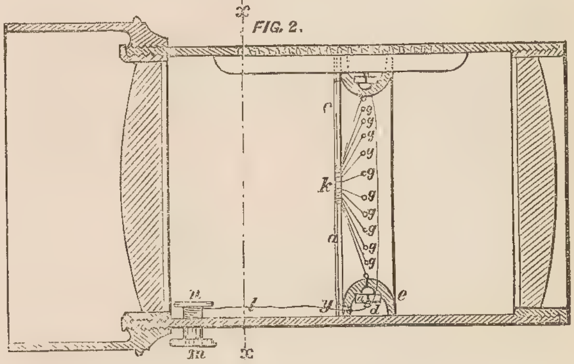
e. A brass or wood ring, with flanges, made to fit into the lens tube like an ordinary stop.

a. A thin sheet of India-rubber, secured round the edge of the front flange.

c. Silk or gut stretchers fastened at one end in the holes *a* round the front flange, the other ends pass through the centre hole *k*, through the holes *g* (see section), and are then secured to the ring *d*, working loose between the flanges.

z. A small eye in the loose ring *d*, in which is secured one end of a length of gut *l*, the other end, after passing over a portion of the outer circumference of *d*, and through the hole *y*, in the front flange—is then fastened to the reel *n* (clearing the focussing rack and pinion).

FIG. 2.



m. A stud screwed into the reel *n*, from the outside of the lens tube, the turning of which will wind on the gut *l*, bring the loose ring *d* into motion, pull up all the stretchers, and produce any sized orifice from a quarter of an inch up to full aperture of lens.

During the past summer I tried various modes of producing the same effect, but found the above *much the best* in every respect. An index may be attached to register the diameter of orifice produced at each change.

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

At the monthly meeting of the above Society, held at Myddleton Hall, January 26th, Mr. W. Hislop, F.R.A.S., in the chair, the minutes having been read and approved, a paper was read by Mr. Legg, "*On the Delineation of Microscopic Objects by Photography, with Artificial Light*," [see p. 31] on which a discussion ensued.

The Chairman was of opinion, that the best method was to take a negative of about one inch in diameter, and enlarge from that, the definition being better, exposure shorter, and the result in every respect more satisfactory; also, that natural was preferable to artificial light, reducing the exposure one-third or even less. He also recommended Mr. Wenham's method of correcting the object glass of the microscope, by placing behind it a common spectacle lens. He kept about a dozen of these lenses at hand, varying from three inches to three feet focus, and by a simple arrangement in the brass tube holding the object glass, it was only necessary to drop in one of these lenses, keeping a register of the one producing the brightest image; much time and vexation was thus saved. Another advantage of taking the negatives of this size was its adaptation to the magic lantern. Some preferred the oxycalcium

light; but he used a mixture of equal measures of oxygen and common coal gas. It was a mistaken notion that it was a very expensive light: six gallons of this gas will burn an hour and a-half, and the cost, including the ball of lime, would be less than one shilling for that time. The Photogen was suggested; but the difficulty of condensing the light, and the necessity for a special apparatus, would be a great drawback to its adoption. The electric light would no doubt answer; but the cost overbalanced its advantage.

A MEMBER suggested the use of a reflector; but Mr. LEGG replied, that he had used one, and discarded it on account of its producing irregularity of light. He did not think the use of reflectors in magic lanterns advisable.

Mr. HANNAFORD then read a short paper "*On some Further Experiments in the Iron Printing Process*," (see p. 36) and produced some very good specimens. Some of the iron pictures were superior to silver prints from the same negative. The principal improvement he introduced was the substitution of albumen for gum-arabic in the sensitising solution.

After an animated discussion votes of thanks were passed to Messrs. Legg and Hannaford, and the meeting adjourned to Feb. 23rd, when the nomination of officers for the ensuing year will take place.

CHORLTON PHOTOGRAPHIC SOCIETY.

THE Monthly Meeting of the Chorlton Photographic Society was held at the Chorlton Town Hall, on Wednesday, the 12th ultimo, Mr. DEAN, the Vice-President in the chair.

Mr. NICHOLSON, in announcing to the Society the sudden death of Mr. Hepworth, the Treasurer and late Vice-President, gave a long and full account of his usefulness to the Society from its commencement, and concluded by moving—

"That this meeting having heard with sincere regret the intelligence of the sudden decease of the late Vice-President of the Association, Mr. Hepworth, desires to express its sympathy with his bereaved widow and family in the great affliction that has befallen them, and also to record not only its appreciation of those many sterling virtues which justly won for him the respect of his fellow members, but also to acknowledge the great services which he rendered to this Association as one of its founders, and the ability and courtesy which he displayed in the discharge of his duties as its first Vice-President, and that a copy of this resolution be sent by the Secretary to Mrs. Hepworth."

Mr. HEYWOOD briefly seconded the resolution.

The CHAIRMAN on rising to put the resolution was prevented by several members saying simultaneously, that it was not necessary; and it was accordingly considered as carried unanimously.

After a silence of some minutes duration,

Mr. ROGERSON stated, that he had intended to read a paper "*On the Enlargement of Positives*," but some apparatus which he intended to use in bringing his subject before the meeting was not ready, and he was obliged to postpone the matter until next meeting. He moved, and Mr. WARDLEY seconded, that Mr. Nicholson be appointed Treasurer, which was carried.

The CHAIRMAN said he thought he had discovered a method of colouring glass pictures which would stand the test of magnifying sufficiently for the magic lantern; he should be happy to try, if some member would furnish him with a picture. The meeting thought it would be a very satisfactory thing if it could be accomplished, and Mr. Wardley promised to provide a specimen for the Chairman to work upon, which he would show at the next meeting in a finished state.

An animated discussion on printing ensued, during which the alkaline chloride of gold, as described in a contemporary, was highly spoken of, and several members finding it economical they discarded the old plan.

A drawing and description of a circular moveable diaphragm for insertion between the two lenses in a portrait, combination which could be opened and closed to any required extent without moving the lenses, was exhibited by Mr. Hope.

Mr. HOOPER explained his mode of washing prints in many changes of water, without attention, by means of a syphon, which only commenced working every time the washing vessel was full.

Mr. WARDLEY mentioned that Mr. Young had produced a picture developed in daylight after fixing by hypo, which was curious; the meeting thought it was an instance of substances being acted upon by light in several ways, for instance, a coin placed on a plate of glass, and exposed to light after reversing for a considerable time, leaves an impression without any other agent being required, and it was thought that a plate of glass was sensitive to light, but not so much so as iodide of silver.

Mr. ROGERSON exhibited a very neat and compact dark slide for dry plates or paper made from millboard, which had been sent to him from the Macclesfield Photographic Society, and could be had for one shilling each.

A vote of thanks to the Chairman concluded the meeting.

Exhibitions.

PHOTOGRAPHIC SOCIETY'S SIXTH ANNUAL EXHIBITION.

WE intimated in our last the opening of this Exhibition, but the great press of other interesting matter precluded the possibility of then giving any thing like a detailed description of its contents. We now propose to make a few remarks upon it by way of criticism, for the purpose of keeping our readers acquainted with that which is going on in connection with our art.

On glancing through the catalogue, we are at once struck by the existence of a fact—a gradual tendency towards which we have before now remarked upon—we mean the increased *professional* character of the display, which has been of late more and more apparent. In the present case, more than nine-tenths of the whole assume the qualification above designated. This is, perhaps, not surprising, when we reflect that the amateur of yesterday is the professional operator of the present day: nor are we at all certain that the fact is one to be deplored; still we cannot but feel some little regret that amateur exhibitors do not now muster in greater force as regards numbers, even although the works contributed by each should be but few. Experience teaches us, that however much professional operators may be able, from constant practice, to excel as regards skill in manipulation, when compared with the generality of amateurs, it is nevertheless amongst the latter class, as a rule, that scientific discoveries, tending towards the improvement of the art itself take place. It would therefore be unwise, as well as unjust, towards those who labour purely for love and not for profit, to deny them a full share of the honours that are to be acquired by a due representation in each succeeding exposition. Not that we have aught on this head to charge against the hanging committee of the present exhibition; on the contrary we have before remarked, that the members of it have performed their duties with unusual success and discretion.

In our opinion there is one great advantage in the Suffolk Street Gallery not easily to be attained elsewhere—that is, a sufficiency of wall space to display the works without the aid of central screens, which take off so materially from the general effect as a whole, and materially interfere with the comfort of the visitor in examining the various productions. The three rooms *en suite* also admit of a very convenient mode of classification of the pictures, tending towards unity of design, without in the least producing the idea of disruption apt to be engendered by portions of a collection being located in different apartments. In a collection of photographs of all kinds, we have always found that stereoscopic subjects collected in one mass in a huge frame—portraits, coloured and uncoloured, and of widely different dimensions—invariably mar the general effect, producing what an artist will recognise by the term *spottiness* in a picture. Now by collecting these together, as is done at Suffolk Street, and arranging them in one of the smaller divisions; the remainder of the collection is freed from the damaging effect before spoken of; and these works themselves are considerably the gainers, being seen to much better advantage than when overshadowed by some huge giant; while at the same time they are not obnoxiously dissociated from their larger brethern, but have rather a post of distinction assigned to them.

The mode of nocturnal illumination adopted, viz., by gas external to the extensive skylight, is very conducive to the comfort of the visitors; but, as few advantages are attained without a corresponding outlay, we have in this instance also the penalty to pay, which we regret to admit is at the expense of a portion of the beauty of the photographs; for, as a rule, these are seen to better advantage the greater the amount of light that is allowed to fall on them, while the pleasant and mellow light produced by the arrangement described is better fitted to the display of paintings or drawings not produced by its agency. We heard the remark

made that it was a capital imitation of a London fog. If so, it must have been an external one; for certainly nothing of a haziness was perceptible within the building, though we felt inclined repeatedly to remark that we were "waiting for more light."

On taking a general survey, we do not find, as on some former occasions, a few subjects standing prominently out from amongst the general mass; but we believe this arises from a very satisfactory cause—we mean that the prominent ones are the few indifferent works that are included; for the generality reach a very high standard of excellence. Of course we took notes for the benefit of our readers; but we find, on going over the catalogue, we have marked so many pictures, that it would be an infliction to specify in detail one-half even of those signalised: we propose, therefore, in the present instance, to make our observations more general than particular.

Amongst the few amateurs exhibiting, we are much pleased to recognise again the handiwork of our old friend, Mr. Rosling, who is a pretty extensive contributor of works of a high order of merit, both by the collodio-albumen and by the ordinary humid collodion processes. We cite Nos. 91 and 599—each frame containing four subjects—as well worthy of careful inspection.

Mr. B. B. Turner has this year a series of architectural subjects, chiefly from Canterbury, taken by the Talbotype process, which is well adapted to render them in a bold and effective manner. Specimens will be found numbered 207 to 211, and 277 to 279, and are of such generally equal merit that it is hard to select one in preference; perhaps, however, that last indicated is entitled to the most honourable mention.

To Mr. F. Maxwell Lyte we are indebted for the display of some very fine and interesting landscape subjects, with natural clouds, of which the most effective are No. 636, *Le Pont de Scia*, and 637, *Saint Sauveur*. Nos. 629, *Bagnerres da Bigorres*, and 630, *St. Béat*, are also very fine.

Of the collection of Messrs. Caldesi and Montecchi's copies of the Cartoons of Raphael, enough has already been said in *The Times* and other daily papers. Their value is greater amongst professional artists and the general public than with photographers, who like to be something more than mere copyists. We have never regarded this branch of the photographer's occupation as one standing in more than a secondary position—very useful, very important in its way, but not tending, in our opinion, to the elevation or progress of photography proper: and we have the hardihood to give expression to this conviction, notwithstanding the risk we run of incurring displeasure for presuming to differ from so great an authority as "the Thunderer."

Mr. Fenton comes out in great force; and we are pleased to notice that he is turning his attention to a department of the "art" in which he is less known than in his exquisite landscapes—we mean those subjects that in *art-slang* are generally designated as *genre* subjects. Of these, No. 43, *The Pasha and Bayadère*—No. 50, *The Reverie*—No. 606, *Turkish Musicians and Dancing Girl*—No. 608, *Nubian Water Carrier*, are favourable examples, being admirable illustrations of Eastern scenes of actual life. Their execution, also, is worthy of Mr. Fenton's well-known fame.——Amongst this gentleman's landscapes there are so many that we covet, that we feel almost inclined to mention the whole of them; but Nos. 34, *Glastonbury Abbey*, and 54, *Raglan Castle*, are especially fine; as also No. 55, *The Central Valley, Cheddar Cliffs*, which has an indescribable charm, the atmospheric effects being truly wonderful. The *South Aisle of Salisbury Cathedral* (No. 63) is a good specimen of the delineation of a difficult subject—an interior; but one of the most interesting as a photograph is No. 69, *Chatsworth: Cattle in the River*,—a perfect Cuyp in its way. In this, we need scarcely say, there is no stiff attitudinising, but life, vivid life, in all its natural grace. Here is a direction in which photography is truly invaluable to the artist: it offers the means of catching truly the "poetry of motion." Photography has dispelled the illusion of the old conventional way of rendering the horse at full gallop, having all four legs radiating from the trunk as from a centre—an attitude never in reality assumed by this animal, except perhaps momentarily in the act of leaping; for when the fore-legs are thrown out, the hind ones are doubled up under the belly, and *vice versâ*.

Mr. Bedford's architectural subjects always impress us with the idea of their having been executed by Mr. Fenton's *younger brother*, so similar are they in style—that is, as similar as a portrait and a minature can be. We do not mean, however, that Mr. Bedford is the least bit of a plagiarist—far from it: he has a style as unmistakeably his own as ever artist had; but, in the particular class of subject named, Mr. Fenton's and Mr. Bedford's ideas seem to run in parallel lines. *Raglan Castle* and *Tintern Abbey*, in all their numerous phases, as shown by Mr. Bedford, are our especial favourites amongst this gentleman's large contribution to the collection, particularly those numbered 88, 99, 118, 130, 137, 139, 143, 145, 149, in which the effect of solidity is something marvellous—they are gems of the first water.

While amongst the architectural pieces, we must not omit to direct attention to No. 178, four subjects at Rouen, by the late Mr. R. Howlett, in whose decease photographers have been deprived of a most skilful and energetic follower of the art. The exquisite delicacy and fidelity of representation of the beautiful sculpture-adorned buildings, as exhibited in this frame, possess a charm that is only to be felt by the spectator; no description can do justice to them. No. 158 contains four views of *St. Ouen*, and the *Cathedral at Rouen*, equally fine in execution; and besides several others are some microscopic studies, No. 519, by the same lamented brother of our craft.

If the art of photography be yet old enough to possess a veteran amongst its votaries, we suppose we may regard Mr. P. H. Delamotte as one of them; but then a photographic veteran does not necessarily indicate an old man. This gentleman exhibits only one picture; but that one contains as much as a dozen ordinary ones, being a magnificent *Interior of the Crystal Palace at Sydenham*, occupying three large sheets of paper, but of a tone so even and so cleverly joined, that only the initiated are able to detect the fact. The most difficult point of attainment in these panoramic views is, not so much the junction of the component lines, as the production of negatives of equal intensity, allowing proofs of the same tone to be printed from the whole of them.

We come naturally next to consider Mr. Frank Frith's still more extensive *Panoramic View of Cairo* (No. 553), consisting of no less than seven large sheets united together. This work we have recently noticed in our review of the Architectural Photographic Exhibition, as well as many of Mr. Frith's other works. We understand that the view of Cairo is intended as a present to the Pasha of Egypt, as some acknowledgment of his kind assistance to Messrs. Frith and Wenham, when engaged in procuring the negatives in the dominions of that potentate.

To those who accuse the collodio-albumen process of being hard and deficient in half-tone, in addition to Mr. Rosling's, we would point to some of Mr. W. Sykes Ward's pictures, as showing that this alleged failing is not *necessarily* the case. More particularly we allude to the upper left-hand picture in frame No. 400.

There is a very charming landscape by Silvy (No. 573), that we should much like to gain some more information about: the effect is very fine, yet not altogether satisfactory—the sky, evidently a natural one, being far too dark for the rest of the subject. We cannot quite make out whether it has been printed from a different negative to the rest of the picture, or from the same: there appear reasons for arriving at either conclusion.

Mr. J. H. Morgan is a photographer quite after our own heart. We should feel tempted, but that we have not his acquaintance, to imagine that he had selected his subjects for our own especial delectation, so completely are they the style that we particularly delight in, and choose when we have the chance. No. 601, *The Nightingale's Haunt*, and No. 614, *The Early Violet's Home*, are enough to make one wish to be *alternately* a bird and a flower. Nos. 612 and 613 are also very beautiful; but we must pause, or our list will look like a table of logarithms.

There are three or four instantaneous pictures, not very striking; but the best is, perhaps, No. 148, *Waves*, by Messrs. Cundall and Downes, which are not merely stereoscopic-sized pictures, but about 8 × 6 inches in dimensions.

Two fine foreground studies—No. 134, *Tussilago*, and No. 146, *Ferns*—by Messrs. Ross and Thomson, are, doubtless, identical with those recently noticed by our Edinburgh correspondent.

We are glad to find that Mr. Rejlander has not deserted us. We always regard his productions with interest, even when they do not happen to be precisely to our taste, because he always works with a purpose. No. 154, *Well!* is very graphic. An old schoolmaster is hearing a scholar, in the garb of a blue-coat boy, say his lesson, in which the latter is evidently not sufficiently "well up;" whilst a friend in need, in the guise of a schoolfellow, is "helping the lame dog over the stile," by aid of what, in our younger days, we used to designate a "crib." *The Scripture Reader* (No. 183) has been before noticed in our columns, as well as several others of this gentleman's works.

Mr. H. P. Robinson also exhibits several that we have before had the pleasure of introducing to our readers—amongst them *Fading Away* (No. 18), and the *Little Red Riding Hood* series (Nos. 13 and 22), which last, by the way, should have been reversed in

their order — a circumstance which gives rise to grave doubts in our mind, whether the hanging committee were well versed in that veritable history. No. 8, *Lulu*, is a charming picture of a charming model. No. 27, *Mariana*, from Tennyson's poem —

> An image seemed to pass the door,
> To look at her with slight, and say —
> " But now thy beauty fades away,
> So be alone for evermore."

The figure is well *posêd*, and the gleam of light on the eyeball (not on the iris) is something striking in its effects. The same model appears in 564, *She never told her Love*, &c., and seems to be able to assume and retain certain expressions of feature in a wonderfully clever manner.

There are some clever subjects by Messrs. Truefit Brothers. No. 10, *Granny's Lesson* — an old woman crouching beside a wooden fence and teaching her little grandchild her letters — forms a very picturesque group. No. 35, *The Rejected*, is also good, and so is No. 70, *Listeners seldom hear good of themselves* — in all, the models not exactly ranking amongst the " upper ten thousand."

Messrs. Delferier and Beer have some pictures which indicate considerable powers of composition in a peculiar style; but there is a slight want of *reality* in the result, and the accessories are rather too crowded. No. 83, two subjects in one frame, called *One Wink* and *Forty Winks*, are however exceedingly good. An old Dutchman appears with a grin and a wink of satisfaction, pouring out of a corpulent-looking bottle, for his private refreshment, no niggardly dose of veritable Schiedam: the companion picture exhibits our hero enjoying his " forty winks," the probable consequence of the previous solitary one.

Amongst the portrait photographers appears a new star, in the person of Mr. Chloponin — we believe a Russian — whose productions are well worthy of critical examination — Nos. 352 and 338 in particular. The former is a lady in a white ball dress, which not only appears beautifully transparent and perfect in detail, but the figure is artistically illumined, and stands out from the background more than any portrait we have ever before seen.

Mr. Williams is still at the head of the English portrait photographers, and exhibits amongst others an excellent likeness of our friend, Mr. Hardwich, whose features will doubtless be scanned with interest by many who know him well by his deeds, though not personally.

Dr. Diamond gives some forcible reminders of well-known faces.

Herr Pretsch exhibits some fine specimens by his photogalvanographic process.

Mr. Burnett has some examples of his uranium, iron, and copper printing. Nos. 384 and 392 are the same as he exhibited some years back at the meeting of the British Association; but they are of present interest, in consequence of his valuable paper recently published in our *Journal* and elsewhere.

We must bring our notice to a conclusion for fear of tiring our readers. We cannot, however, but feel, that long as we have been obliged to make it, we have not half exhausted the many interesting matters for discussion presented to us.

NOTTINGHAM PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The first Exhibition of this Society was opened at the Exchange Rooms with much *eclat*, on the evening of the 7th ult. The *conversazione* was attended by nearly four hundred of the principal families of the town and neigbourhood. A band of music and refreshments were provided, and the arrangements gave general satisfaction. The works exhibited are the productions of many of the most eminent photographers, both English and continental, amongst which the specimens contributed by the members of the Nottingham Photographic Society are conspicuous. We noticed the fine landscapes of Mr. Roger Fenton; the architectural views of MacPherson and Bisson *frères*; the portraits by Maull and Polyblank; the *tableaux* of Lake Price, Robinson, and Rejlander; the studies, by Mr. Thurston Thompson; the sea-scapes of Le Gray; and the illustrations of astro-photography, by the Padre Secchi, by Nasmyth, and Sidebotham. Mr. Frith's views in Egypt and Palestine are also very conspicuous. There are two views at Rouen, taken by the late Mr. Robert Howlett, with the *Petzval* lens, which possess a melancholy interest from the premature decease of this excellent artist. Of local contributions among the most noticeable are the works of the Rev. J. J. Dredge, of J. F. Hurley, Mr. Woodward, J. Bourne, Dr. Goode, of Derby, Miss Hurst, of Alderwasley, Mr. Nowall, Mr. Cotesworth, Archibald Briggs, the Rev. J. Holden, Alfred Rosling, and Mr. Smith. The prize pictures are *West Door, Southwell Minster*, by the Rev. J. J. Dredge; *Newark Castle*, by J. F. Hurley; and *Cottages at Wilford*, a stereograph, by Mr. Woodward; copies of these are presented to subscribers. Mr. Rosling has presented four fine landscapes, and Mr. Sidebotham, of Manchester, has also presented three landscapes. Mr. H. P. Robinson, of Leamington, has presented a copy of his popular picture, *Fading Away*.

In the room appropriated to apparatus, chemicals, &c., Mr. Atkinson, of Liverpool, exhibits a lens, said to be the largest in England, and a solar camera. There is also exhibited a goodly array of cameras, tripod stands, tents, dark boxes, stereoscopes, and stereographs, contributed by Messrs. Ottewill, Thompson, Horne and Thornthwaite, Woodward and Shepperley. Dr. Hill Norris contributes some very fine stereographs on glass.

The exhibition has been well attended, and altogether is very creditable to the energy, industry, and skill of the gentlemen who organised it. A great impulse cannot fail to be given through its means to the art of photography in Nottingham and its vicinity; and we shall not be surprised to see other provincial towns profiting by the example.

Processes.

IRON PRINTING PROCESS.

By Michael Hannaford.

(Read before the North London Photographic Association, 27th Jan., 1859.)

Since our last meeting I have substituted albumen for gum-arabic in the sensitising solution with considerable advantage. I beat up, in the usual manner, albumen one part, water two parts — or equal parts of each, if a high glaze is desired — together with —

Bichromate of potassa, to saturation;
Ammonio-citrate of iron, 10 to 15 grains to the oz. for under-exposed negatives with strong contrasts; 15 to 20 grains to the oz. for good negatives; and 20 to 30 grains to the oz. for over-exposed weak negatives.

I make, also, the following solutions: —

1. Liq. ammonia, about 1 oz.; water, 1 pint.
2. Chloride of gold, 1 grain; water, 4 ozs.
3. A saturated solution of gallic acid (or a hot solution, containing from 2 to 4 grains to the ounce, can be made as required for use).

I use the thick French papers albumenised. To sensitise the paper, float it for two or three minutes, and hang it by one corner to dry. If the albumen has not been well beaten up, the paper will not be evenly coated.

After exposure under a negative, the print must be immersed in water for from half-an-hour to, comparatively speaking, any length of time. Most of the specimens exhibited were immersed from one to four hours. One has been soaked *for more than a week*, without the slightest difference in the result, so far as I can see.

Now transfer the picture to a bath of the ammonia solution, in which it should be allowed to remain for about five minutes. This will clear the whites. Then put it into the gold toning bath for from five to ten minutes, first giving it a rinse in clean water.

The picture is now ready for developing, which is effected by placing it on a clean glass plate, and pouring on the gallic acid solution. In case of over-exposure, the details will not come out readily, but sufficient of the ammonia solution to cover the paper, poured on at one end, and allowed to escape into the waste pan, will have almost a magical effect.

I usually finish by laying the picture on a flat dish, and pouring boiling water over it.

[Mr. Hannaford has emphatically expressed his obligations to the writings of Mr. Burnett on this subject — the former is working out, in a manageable form for those not possessed of Mr. Burnett's chemical abilities, the principles enunciated by the latter. — Ed.]

QUICK Versus SLOW PROCESSES: THEIR COMPARATIVE MERITS.

By F. B. Gage.

It has been a great desideratum among artists to procure some process whereby pictures may be taken in the twinkling of an eye, and therefore we see almost every artist running semi-crazy after any new nostrum that is proposed to take impressions in a moment. These processes are all advertised by their respective discoverers and proprietors, as producing a little better result

than any other method heretofore known. I recollect purchasing a quick process several years ago; it proved to be all that it was recommended in regard to quickness, for it was quick in every sense of the word. It took just a fraction less than no time to take an impression, and the impression generally proved to be just a fraction worse than none. The pictures were sure to be too white, or too flat, or too yellow, or too any thing but just right: and I soon threw the stuff away and returned to a reasonably slow process. Not long after I met a quick process in some journal, which was said to be just the thing and "dead sure;" so I resolved to try it again. I prepared the chemicals and at it I went, fully prepared to conquer the baby chemicals as well as others. My patience held out remarkably well on this process. For two weeks I persevered, fully resolved to conquer, but at last endurance could hold out no longer. Such burlesques of the "human face divine" were horrible! I pitched the stuff out of window, and delivered myself in this wise—"Go to thun——!" (that is a dreadful noisy word, Mr. Editor, therefore I will not repeat it, for I am not commonly called a profane man).

When the ambrotype process first came out it was stated to be a great deal quicker process than the daguerrotype. This was good news, and all the babies in town laid awake every night for three weeks and practised crowing, that they might have their pictures taken in that interesting exercise, by this new wonderfully sensitive process. When, however, the matter came to be tested, it was found that—like the daguerreotype—the quicker the process the more uncertain the result. It was found that the ambrotype had but little advantage, except that the developing could be pushed and a half-exposed impression rendered saleable with any amount of distorted lights and shades. A very sensitive surface, with a strong light, would either fog or flatten, or some mischief was sure to follow, so that a gem was the exception and not the rule; while with a slow process, the gems were the rule, and the inferior impressions the exception. And there is a reason for this—an insurmountable law of nature. Any compound that is very sensitive to light is equally sensitive to atmospheric and other changes, while the surface that is slow to receive the impression of light is equally slow to change from other causes. All quick processes are, from their very nature, unstable and are not to be trusted. There is, however, a point beyond which a process is found to be too slow to produce good results. Therefore a medium between the extremes seems best. With a moderately strong light, from 25 to 60 seconds will usually warrant the best results in a daguerreotype. With the ambrotype, from 25 to 50 seconds, and from 30 to 75 for a negative portrait. With a good light (100 square feet of skylight) and chemicals to work at about these rates, I have been able to produce results that were uniform, and those that were not compelled to go begging either for praise or patronage. Hence, when asked my opinion about the merits of any new quick process, my answer is usually found in the old adage—"*Slow but sure.*"—*Humphrey's Journal.*

Letters to a Young Photographer.

No. III.

My Dear Eusebius,

If you wish to become an accomplished photographer, you must above all things practice patience. Do you think such a noble art can be learned in a day, or taught, like writing, in six lessons? If you practice it all your life, you will be but serving your apprenticeship to it. As the poet wisely said, "Art is long and life is fleeting!" and you must win your laurels by persevering study and exclusive devotion to your idol. I would not discourage you with magnifying difficulties; but, as I know you would not be satisfied to remain a bungler in our art, I am desirous that your progress should be slow and sure. Why, it takes seven long years to make a carpenter or a shoemaker; and is not the photographer as great a craftsman as either, and can you expect he will be turned out complete in as little time as it takes to make a pair of shoes? Patience, then, my dear Eusebius, and you shall have your reward. Everything will come at the proper time and in the proper place. If I told you everything at once you would forget half and misunderstand the rest.

Somebody has told you that five per cent. of hydrochlorate of ammonia is not enough! Well then, I can tell you beforehand what will happen if you double that quantity. When you come to float this strongly salted paper upon the silver solution, chloride of silver will be formed in such quantity, that it will be precipitated instead of forming a thin layer on your paper, which will present a mottled appearance when it is exposed to the light, and spoil any pictures taken on it. Besides, the more chloride of ammonium you employ than is necessary, the more nitrate of silver is decomposed, and the surplus is waste, and the toning and fixing are rendered more difficult. You will find, I am sure, that a weak solution of chloride of ammonium is better for your purpose than a strong one, provided you do not go into the opposite extreme.

But your salting solution may become too strong, if you do not take into consideration that when exposed in a broad, shallow vessel it evaporates, and becoming more concentrated will produce the effects I have pointed out, if you do not take measures to obviate them, by adding each day, when you return the salting solution to the stock bottle, half an ounce of water to the pint. In a warm room or during summer weather evaporation goes on very rapidly, and must be taken into account. With these precautions you may now venture to proceed to sensitising the salted paper on the bath of nitrate of silver. Make a solution by adding one ounce of nitrate of silver to eight ounces of distilled water, filter, and keep it in a black bottle. Pour a sufficient quantity of the solution of silver, of the strength indicated, into a flat, shallow, porcelain or glass dish, and float the paper on it in the same manner as for salting, carefully avoiding bubbles, or wetting the back of the paper with the silver solution. You understand, I hope, that it is the salted and albumenised surface of the paper that must lie on the silver solution, and it may remain floating for about five minutes; then lift it up gently by one corner, and let it drain into the dish; when the silver solution ceases to drop freely, hang it up by a black pin, and attach a piece of blotting paper to the lower corner of the sheet of paper. Every sheet of salted paper floated upon the silver solution, besides abstracting a certain quantity, reduces the original strength of what remains. It is a good plan to frequently replenish the bath from a stock bottle of solution of greater strength—say one ounce of silver to seven ounces of water—so as to keep up the normal strength of the bath.

I cannot insist too strongly upon the necessity for perfect cleanliness in this operation: the dish into which the silver solution is poured must be carefully wiped out with a clean cloth; the room must be free from dust, and the hands from other chemicals employed in the various operations. Sometimes a thin pellicle or scum forms on the surface of the solution, caused by the reduction of the silver by particles of dust, &c. settling upon it. This may easily be removed by collecting it in one place by means of a slip of writing paper, and removing it out on one side of the dish. If this scum adheres to the surface of the paper, the proof will be stained.

The room in which this operation is carried on must be lighted with a small taper, or what is better, by daylight passing through one or two panes of orange-coloured glass. On no account must gas be burned in the room; for during its combustion, sulphurous gases are given off, which attack the silver paper while wet, and form on it a multitude of black spots of sulphide of silver.

It is best not to silver more paper than you are likely to use in a day; for in the course of a few hours after the paper is silvered, it begins to turn brown, and the proofs acquire a dull, heavy hue, which no subsequent operations, at present known, are sufficient to remove.

There are some persons who will advise you to add acetic acid to your silver solution, but pay no heed to such evil counsel; the effect of acid in the paper is to cause spots to appear in the proofs when they are submitted to the fixing solution. The solution should be neither acid or alkaline, but neutral to test-paper; and if the bath becomes slightly alkaline from contact with the chlorinated paper, the ammonia will evaporate from the paper in drying, and leave it neutral. The effect of alkalinity is to retard the action of the light, and render the printing process very slow and tedious.

In the course of time you will find the silver solution acquire a deep crimson-red colour, owing to the action of the albumen on the silver. This is not productive of any mischief, provided it does not leave a permanent stain on the paper. You will filter the solution through paper, at night, when returning it to the stock bottle, adding to every pint of the solution five to ten drops of a solution of common salt, of the strength of twenty grains to the ounce of water, agitating the whole immediately, and letting it settle; if, in the course of an hour or so, it does not become limpid, add a few drops more. This is a much better plan than clearing by kaolin, pipe-clay, or fuller's earth. Half a drachm of the solution of salt contains about one grain of salt, which will precipitate about three grains of chloride of silver; this need not be wasted, but may be added to the residues.

The paper, when dried, is ready for the printing frame. It should not be allowed to hang in the air any longer than is necessary to become dry, as sulphurous emanations everywhere abound, and are sure to cause spots in the paper.

With this I send you half a dozen negatives to try your hand upon; they are picked to show you the various results of different modes of exposure, developing, &c. By carefully studying the positives in conjunction with the negatives, you will soon be able to judge in what a good negative consists. Some of these negatives are very dense, owing to excessive development: they will require very long exposure in the printing-frame. Others are thin, and will print very quickly: the true medium will, on comparison, be very evident to you.

There is another mode of positive printing, known as "printing by development," which I think it unnecessary to speak of at the present time, as in your stage of initiation it would serve no other purpose than to confuse you. One thing at a time must be your maxim. By the time you have got proofs printed from these negatives, I shall have sent you some information as to the best methods of toning and fixing.

Photographic Glossary.

Catalysotype — A process in photography invented by Dr. Woods, which depends upon a *catalytic* action set up by the salt of silver, which is afterwards continued by the salts of iron. The pictures obtained are negatives on paper. "It is said to have all the beauty and quickness of the calotype without its trouble, and very little of its uncertainty."

Centigrade Scale — The scale usually attached to thermometers in France and other continental countries, in which the space between the freezing and boiling points of water is divided into 100 degrees.

Centimetre — The hundredth part of a *metre*, or of 39·7 inches: it measures 0·393 inches or two-fifths of an inch nearly.

Cereoline or Cerin — A principle obtained from bees' wax by the action of boiling alcohol. It is employed in the waxed-paper process as a substitute for bees' wax.

Chlorides — Combinations of the bases with the gaseous element chlorine. The chlorides are used for salting paper in positive printing processes.

Chloride of Gold — A compound of one equivalent of gold united to three equivalents of chlorine, forming a solid reddish-orange salt, soluble in water, alcohol, and æther. It is very deliquescent, and must be preserved in sealed bottles. It is an agent in toning positive proofs, and forms the *fixing* agent for daguerreotype plates.

Chloro-bromides — Compounds of chlorine and bromine used for *accelerating* in the daguerreotype process.

Chloroform — A heavy, limpid fluid obtained by distilling alcohol or wood spirit with chlorinated lime. It is soluble in ether and alcohol, but insoluble in water. It is a solvent of gutta-percha, wax, the resins, caoutchouc, and camphor.

Chloride of Silver — One of the principal agents in photography, particularly in positive printing. It is composed of chlorine combined with silver, and is formed whenever a soluble chloride is added to a soluble salt of silver, such as nitrate. Chloride of silver is soluble in ammonia and in the alkaline chlorides, bromides, iodides, cyanides, and hyposulphites, but is quite insoluble in water and in the acids. When pure, ordinary chloride of silver darkens rapidly in the light. Dr. Percy recently demonstrated, that if produced by the direct union of chlorine and silver in a minute state of division, no blackening by the action of light follows. There is a sub-chloride of silver which has been the object of many interesting experiments in obtaining colours in photographic pictures.

Chloride of Platinum — More correctly bichloride, as it is a combination of two equivalents of chlorine and one of platinum. It has been substituted as chloride of gold as a toning agent in positive printing.

Chloride of Sodium — Familiarly known as culinary salt. It is a compound of chlorine and sodium. It is employed in photography for "salting" paper in positive printing, but is not so good for that purpose as chloride of ammonium.

Chlorine — An elementary gaseous body of a greenish yellow colour and strong irritating smell. It is soluble in water, to which it imparts its properties, and exercises a very energetic bleaching action upon vegetable bodies. In combination with the various bases it forms *chlorides.*

Chromate of Silver — A crimson-red salt, consisting of chromic acid and oxide of silver. It is decomposed by light in the presence of organic matter.

Chromic Acid — A per-oxide of the metal chromium, which, in combination with the bases, forms salts, termed chromates. As a photographic agent it possesses much interest and value.

Chromates — Combinations of chromic acid with various bases. The principal chromates used in photography are bichromates of potass and chromate of silver.

Chromatype — A photographic process invented by Mr. Robert Hunt, based upon the action of bichromate of potash upon sulphate of copper, the picture being developed by nitrate of silver or of mercury.

Chrysotype — An ingenious photographic process invented by Sir John Herschel, dependent upon the reaction between chloride of gold and ammonio-citrate of iron.

Citrates — Combinations of citric acid with various bases. The principal photographic citrates are those of soda, silver, and mercury.

Citric Acid — The acid of lemons and other fruits. It is readily soluble in water and in alcohol. It is used in photography in conjunction with pyrogallic acid as a developing agent for collodion negatives, in which it sometimes advantageously supersedes acetic acid.

Collodion — A solution of gun cotton in æther, introduced into photography by the late F. Scott Archer. The collodion, when iodized, is poured upon a glass plate, and the æther evaporating leaves a thin transparent film, of uniform and tenacious quality. Collodion is an inert substance, the part it performs in photographic operations is like that of albumen or paper; it is a support or vehicle for the sensitive salts of silver.

Cyanide of Potassium — A compound of cyanogen and the metal potassium. It is made for commercial purposes (mixed with a portion of cyanate of potash) by mixing eight parts of perfectly dry ferro-cyanide of potassium with three parts of carbonate of potash, and keeping the mixture at a red heat until all the gases are evolved. This salt is largely used in photography, particularly in the positive collodion processes for dissolving out the iodide of silver, removing stains from the fingers, &c. It is highly poisonous.

Cyanide of Silver — A salt composed of cyanogen and silver. It is white, insoluble in water, but soluble in cyanide of potassium. Being easily acted upon by light, it is applicable to photographic purposes.

Cyanogen — A gas composed of carbon and nitrogen, which, in most cases, acts like an elementary body, such as chlorine, bromine, or iodine. The combination of cyanogen with basic bodies are *cyanides,* some of which are used in photography.

Cyanotype — A photographic process invented by Sir John Herschel. Ferrid-cyanide of potassium is the agent employed: when acted upon by light it is converted by it into "Prussian blue;" it is fixed by washing in carbonate of soda. Another method is to submit ammonio-citrate of iron to the action of light, and then develope the picture with ferrocyanide of potassum.

Foreign Correspondence.

Paris, January 25, 1859.

Under the favour of bright skies with increasing actinic power, our photographic artists are busying themselves in preparing their choicest productions for the forthcoming exhibition. Having lain fallow for a year, we may look for a rich and vigorous crop of sun pictures, which shall, doubtless, eclipse all former displays. From what I see and hear, a "toning" fever has set in lately, and, like "dry collodion," threatens to become epidemic. About a year ago, M. Gustave Le Gray, so well known by his very choice pro-

ductions, deposited with the *Académie des Sciences* a sealed packet, containing a new method of toning with chloride of gold. At the last meeting of the *Académie* this packet was opened and read; but previously the author had communicated to M. Regnault some modifications in his formula, which is of sufficient interest to command the notice of photographers generally. He first washes the proofs, upon removal from the printing frames, in two changes of water, to remove the free nitrate of silver from the pores of the paper. The proofs are then immersed in a bath composed as follows:—Distilled water 1000 *grammes* (35½ ounces), chloride of lime three *grammes* (46 grains); filter and then add—chloride of gold one *gramme* (15 grains), dissolved in 100 *grammes* (3½ ounces) of distilled water.

In this bath the proofs acquire a black tone, which tends to become more and more *bluish*, while the *whites* acquire great purity and brilliancy. The maximum effect is produced in about ten or fifteen minutes, according to the colour desired. An immersion of one minute in this bath will give violet-red tones after fixing in hypo, while deep blue-black tones require an immersion of one or two hours. During this interval of time the proofs pass through all the intermediate tones until the shadows are quite black; after which they become blue, and lose their beauty, it being understood that these remarks apply to the appearance of the proofs after they have been fixed in hypo. There is, therefore, an ascending and a descending period of toning, which must be carefully watched. After removal from the gold bath, the proofs must be quickly washed in two changes of water, to remove the chloride of lime, and next immersed in a solution of one part of hyposulphite of soda in six parts of water. The chloride of silver is dissolved out in ten or fifteen minutes, according to the temperature. The proofs lose a little of their blue-black tone, and become more violet. If satisfactory tones are obtained, the proofs may now be washed in the usual manner; but to secure the greatest chance of permanency, it is advisable to immerse the proofs in another bath, composed of distilled water forty-two ounces, hyposulphite of soda seven ounces, chloride of gold thirty grains. The proofs must remain in this bath at least fifteen minutes, but they may be left in it longer, if the desired tone is not then obtained. Washing in warm water is more effectual than in cold.

You doubtless heard, last summer, of the wonderful box invented by Mr. Cognacq, of Rochelle, for preserving sensitised positive paper for an indefinite time, without its becoming discoloured. They were sold at a big price—60 and 80 francs; but as they appeared to answer the purpose for which they were designed most effectually, they set the curious philosophers to work to discover in what their principle of construction consisted; and as there can be no secrets long kept in photography, this one has leaked out. Messrs. Davanne and Girard, whose researches in positive printing are so interesting and valuable, investigated the principle upon which such boxes are constructed, and they have found that nothing more is necessary than to make them air tight. Sensitised paper put when quite dry into such a box, instead of into a portfolio, will preserve its colour and sensitiveness for a time at present undetermined, but which certainly exceeds a month. Now this is a real boon to photographers, and I hope will be acknowledged without cavilling. A stock of sensitive paper can be prepared in dull weather and kept ready for use without the slightest deterioration. At the last meeting of our Society, M. Quinet exhibited a series of positive proofs, obtained by means of a paper prepared in a particular manner, and which possesses the property of keeping its properties during many months without alteration, either before or after exposure in the printing frame. The fixing is performed as quickly as usual, and the proofs are quite permanent. M. Quinet keeps this process a secret, but doubtless some of your readers will soon ferret it out.

The regulations and conditions of the forthcoming Photographic Exhibition are just announced. It will be open from the 1st of April to the 15th of June. Works intended for exhibition will be received *only* from the 1st to the 15th of March, and must have the name and address of the artist affixed, accompanied by a letter containing a list and description of the works sent. The process by which the pictures are taken must also be specified. Coloured photographs, and all such as are *touched* so as to modify the photographic result by substituting a mechanical process, will be excluded. The prices of works for sale may be communicated to the Secretary, M. Martin Laurelie, but they will not be allowed to be attached to the frames of the pictures. Works rejected by the Committee must be removed within ten days after notice of the rejection is given to the exhibitor; and exhibited works must be removed from the Exhibition within eight days after it is closed.

The process of photolithography, by Messrs. Cutting and Bradford, of Boston, lately patented in London by Mr. Newton, appears quite analogous to that communicated two years ago to our Photographic Society by Messrs. Rousseau and Mussor. When I saw that this communication came from America, I had my doubts of its real origin there, and my doubts are well confirmed.

Correspondence.

ON THE THEORY OF DRY COLLODION PROCESSES.

To the Editor.

Sir,—On perceiving in your *Journal* of the 15th instant a communication by Dr. Hill Norris, "On the Theory of Dry Collodion Processes," I found myself very speedily cutting the leaves to ascertain what his views were upon that subject. Dr. Norris's remarks upon previous occasions have been so clear and judicious, that I have more than once had it in my mind, as a member of the Photographic Society, to request the republication of his papers in the Journal of that body. I confess, however, that on this occasion I am a little disappointed, and am inclined to enter upon a friendly controversy with him, if it should appear to you that the subject will gain by a free discussion. To pass therefore at once to the point at issue, I may observe, that as our knowledge increases, and fresh facts are brought to light, it becomes, to my mind, more and more evident, that the essence of all dry processes lies in affinities existing between the sensitive surface of iodide of silver and certain forms of organic matter combined with nitrate of silver. *Porosity* of collodion may be favourable to penetration by the developer and quick developement—of that I have no doubt; but mere porosity is not, as I suppose, sufficient to establish the conditions necessary for a dry process. I have prepared a collodion very pure and quite porous, but was unable to obtain a picture with it until it had been kept for a time after iodising. Did the keeping render it more open in structure? It may have done so to a slight extent; but it is more reasonable to refer the improvement to the separation from the iodide of a portion of its base, potash or ammonia, and to the decomposition produced in the collodion by the liberated base, which would have the effect of forming a trace of an organic compound of silver in passing the film through the bath.

A short paper has lately appeared by Mr. F. G. Eliot, in which he states, that if you precipitate citrate of silver in a bath containing iodide of silver in solution, the iodide is carried down with the citrate. This evidently shows an affinity between the two above-named salts; and there are many reasons for thinking that a similar affinity exists between chloride or iodide of silver and other organic compounds. It may be proved to be so, for instance, in the case of *glycyrrhizine*; for whatever quantity of iodide of silver a nitrate bath of a given strength is capable of dissolving, it will take up a larger quantity when previously saturated with this resin-sugar.

The above experiments bear closely upon the question at issue, and show that we cannot correctly represent a washed collodion film of iodide of silver by the formula $Ag\,I$, unless we are quite sure that both the film and the bath are absolutely free from organic decomposition. If a change has taken place in either, then the film becomes $Ag\,I + Ag\,O\,(C\,H\,O)$, taking $C\,H\,O$ to represent the organic matter, and not necessarily supposing that the two constituents above expressed are present in equivalents, or that their relation to each other is definite and constant.

Pure pyroxyline appears to be neutral with regard to salts of silver; but is pure pyroxyline ever used in the dry processes? My experience goes to show that the more carefully you make the collodion the worse the result. Select a sample prepared from old linen at high temperatures, and you may perhaps get a picture almost immediately after iodising; but such pyroxyline cannot be esteemed to be either pure or neutral in its affinities; and we are not able to assert, that after passing through the bath, and subsequent washing, it is free from all traces of nitrate of silver, or that the iodide of silver rests *mechanically* upon it. On the other hand, it is almost certain that there is a loose chemical union between the

iodide of silver (or a portion of it) and pyroxyline of this description; for it has been observed that the *colour* of the film on decomposed collodion is frequently changed from yellow to opalescent blue, just as it would be if you added glycyrrhizine, or dissolved the iodide in *albumen* in place of collodion? This *blueness of film*, when it happens, is conjectured to depend upon an association of the iodide of silver with small quantities of an organic compound of silver.

But there are other kinds of pyroxyline which are comparatively stable, and consequently, as I suppose, less fitted for a purely dry process. How do we proceed in such a case? Either by bringing about decomposition with liquor ammoniæ added to the plain collodion, or by keeping the collodion for a time after iodising with an alkaline iodide. In either case a trace of alkali combines with organic elements of the pyroxyline and forms an organic salt of silver when the film enters the bath. The iodide retains these traces, and no amount of washing will leave the film in a condition to be represented by Ag I.

I do not however assert, that the presence of organic matter in the film will invariably secure success in a dry process, but simply, that such a process will not succeed if organic matter be absent; and further, that a communication professing to treat of the theory of dry processes in general cannot be esteemed complete without some allusion to this subject. The views which I have stated are not hypothetical, but are based upon experiments which I shall be happy to bring forward if required. I may perhaps be mistaken in supposing that Dr. Norris takes a purely mechanical view of the whole question, but if such be the case, I feel convinced that it will eventually be shown that he is in error.—I am, yours, &c.

F. HARDWICH.

King's College, January 19, 1859.

ALLEGED IMITATION OF THE PETZVAL LENS.

To the Editor.

Sir,—The smallest lens that I have at present for taking portraits is a ¼ plate one; but as some friends wanted smaller pictures than I could take with it, I thought that were I to combine my ⅓ plate and ¼ plate lenses, I should be able to produce a smaller picture at the same distance. I have tried, and succeeded in doing them one-half smaller, and a little quicker.

I merely fixed the one combination to *the end of the other* by means of a piece of card-board and elastic bands, placing the smaller behind the other, both being in their usual position as regards back and front lenses.

I do not know whether this style of imitating Petzval lenses has been tried before; but, hoping I have not intruded upon your valuable time, I am, yours, &c., A. R.

P.S.—I send a small picture on leather; it is not a very good one, but it is the best I have of the kind at this moment taken by the above combination.

[The picture sent is a very sharp positive on leather, the only difference observable, except the reduced size, being a little extra distortion at the edge, producing a somewhat more than ordinarily enlarged *foot* of the sitter. Our correspondent is, however, quite "at sea" in supposing that the combination at all resembles the new Petzval lens.—Ed.]

Glasgow, 11th January, 1859.

A NEW "WRINKLE."

To the Editor.

Sir,—Shellac dissolved in wood-naphtha, as suggested by some gentleman lately, answers *well* for coating the gutta percha bath—in fact, after its use, an old-put-by-bath solution worked well again, much to my surprise: all the striæ and *moiré antique* marks have left, as if St. Patrick had been at work!

In return for that gentleman's communication, I will tell you of a contrivance, new to myself, at least, arising out of his suggestion.

My large floating bath required about 80 oz. of silver solution, because of the *concavity* of the bottom; and I often shook my head at the expense when filtering it. Lately, I bethought myself of pouring a solution of shellac into the *hollow*, so as to fill it up to the level parts near the edges. I did so, and put it outside the house; and, though it took nearly a day to get set, it is now quite as I wished it—a smooth, level surface, requiring but fifty or sixty ounces.—I am, yours, &c.,

O. G. REJLANDER.

Wolverhampton, January 19th, 1859.

BOTTLE DIAPHRAGM.

To the Editor.

Sir—In the last number of your *Journal* appears a letter from a Mr. Ross, recommending the use of a diaphragm, of the shape of a Florence flask, on the score that clouds might be taken in a landscape, because the sky would get *less* light than the rest of the picture.

How any practical photographer could have made such a blunder I cannot conceive, as the fact is the very reverse. The addition of the neck has the effect of increasing the light admitted to the sky. The upper part of the diaphragm should be *flattened* (not elongated) to have the desired effect.—I am, yours, &c. B. JONES.

Cheltenham, 12th January, 1859.

[We think our correspondent does not correctly apprehend the point of Mr. W. Ross's remarks—the neck of the bottle is not an *addition* to the aperture, but a portion of the usual opening is taken away by the lateral pieces to form the neck.—Ed.]

PRINTING DIFFICULTIES, &c.

To the Editor.

Sir,—I heartily wish you success with your new edition, it seems to be much superior to the old one. Will you kindly help me out of a difficulty: I am not at all successful with Mr. Hardwich's new toning bath. I cannot get the whites clear, and when I put the print into the fixing bath, it very materially loses its brilliancy of colour and becomes cold. Will you also tell me your opinion of M. Vallantin's lenses (double). With heartfelt wishes for your success, I am, yours, &c.

DUBLINENSIS.

P.S.—Will you give me your candid opinion of your own jolly old honey process, and the new modified oxymel processes.

[Mr. Hardwich's process is a truly excellent one, and if you fail it must be from some error in manipulation. Your pictures must not be *over printed*, that is to say, the *lights* ought not to be discoloured in the printing frame, otherwise, when put into the toning bath, they will of course get a coating of gold, and so never become clear. It is most likely that here your error lies. If your proof becomes cold in tone, it is because you leave it *too long* in the toning bath. A very short time is sufficient to effect the toning, and about ten minutes for fixing. Change the first two or three waters, after fixing, within two or three minutes' time of each other.

We have never even heard of the lenses you mention.

Your last question is rather personal, but we will try and be impartial in our reply:—

If the plate be intended for use within twenty-four hours after preparation, we much prefer our own process and always use it; but if it be intended for keeping an indefinite time, we think Dr. Norris's dry process better, as also the collodio-albumen. We have not any affection for acetic acid when not absolutely requisite; but Mr. Llewellyn's pictures speak volumes for the capabilities of the process; therefore, our preference is very likely only prejudice.—Ed.]

ANSWERS TO CORRESPONDENTS.

A. Brothers.—We have forwarded your letter to Herr Pretsch, 162, Great Portland Street, who will no doubt reply.

Nil Desperandum, &c.—Positive printing by developement is not to our fancy, the results being rarely so brilliant as by the ordinary method of sun printing. We have been most successful, however, by using Hollingsworth's *thick* paper, salted, by floating for about one minute to one and a half upon a solution of chloride of ammonium ten grains, gelatine two grains, water one ounce. Sensitise upon a forty-grain bath of nitrate of silver, expose until a faint image appears, develope by *floating* on gallic acid, *freshly dissolved*, to which is added *one drop* of a saturated solution of citric acid to six ounces of gallic acid solution. When sufficiently intense, wash immediately in *salt and water*, a spoonful to the pint, and afterwards in several waters. Fix with hyposulphite of soda, and tone with chloride of gold very slightly acid.

B. B. F.—We do not approve of long soaking in washing paper proofs; better far to change the water frequently, and hang up each print for a few minutes to drip before putting into a fresh dishful of water.

D.—With lenses of four inches focus for stereoscopic pictures, their distance apart should be $2\frac{1}{2} + 1\frac{1}{4} = 3\frac{3}{4}$ inch to correct to some extent the error arising from viewing these pictures at a distance of six inches from the spectator. If you employ glasses six-and-three-quarter inches long, and have each picture even as much as three inches wide two-and-three-quarter inches is the usual width), you can place your lenses at three-and-three-quarter inches apart by allowing the two pictures to be formed on the *ends*, leaving the spare glass between them. This is just as convenient, as they must be *reversed in position* before insertion in the stereoscope.

Received—"O. G. R.," and "Practical Photography on Glass and Paper." 4th edition. Review in our next.

A number of articles in type are left over.

Owing to the late hour at which a portion of the copy for our last number came to hand, a few typographical errors escaped correction.

THE PHOTOGRAPHIC JOURNAL.

No. 88, Vol. VI. — FEBRUARY 15, 1859.

In the first number of the present volume, we solicited the attention of our readers to the phenomenon of developement of the photographic image upon collodio-albumenised plates in ordinary daylight *after removal* of the iodide of silver — a phenomenon first noticed by Mr. J. H. Young, and communicated by him to the members of the Manchester Photographic Society. In the following number, at page 28, we published a communication from Mr. Young upon the subject, in which some further particulars were given, and a misapprehension corrected relative to the supposed destructive action of cyanide of potassium as regards the latent image, which appears not to be removed, as was at first supposed, but is simply rendered more sluggish in the subsequent developement.

We have frequently pondered over this interesting point since we became aware of it, as well for the purpose of pressing it into our service practically, as to account theoretically for the existence of the phenomenon. We before hazarded a suggestion as to the probable *rationale*, and we now propose to consider it further, partly with a view to enlisting a larger band of experimentalists to prosecute researches in a very promising direction, and partly to call to mind some few facts already known, which appear to us to bear upon the subject.

It is possible that the persistence of the latent impression may be due to the existence of one of the following causes, viz., 1st, an absolute chemical change, such as a very slight amount of reduction; or 2nd, an allotropization, such, for instance, as that undergone by oxygen in its conversion to ozone, or of phosphorous in its amorphous condition; or 3rd, a changed molecular condition of that part of the surface affected by the light. That the molecular condition of the surface exerts a very marked influence on the susceptibility to the actinic impression there can be no doubt whatever, and we have before had occasion to refer to the existence of this fact. The striking experiments performed by Mr. Wenham with collodion upon ivory, in conjunction with many others tending to similar results, forbid our arriving at any other conclusion.

The effect of allotropization is manifested in the power possessed by ozone to liberate the iodine from its combination with potassium, in the well-known haloid salt, iodide of potassium, whilst ordinary oxygen is deficient in this quality.

The capability of intensification by further developement, where even a small amount of metallic reduction has previously been effected, is a circumstance too well known to photographers to need further exemplification.

If either the first or the last of these suppositions be correct, it is not unreasonable to suppose that a careful *microscopical* examination of the impressed film before developement, but after the iodide of silver is dissolved out, may tend to throw some light upon our investigations; and we may possibly also gain further information by the employment of polarised light. At any rate we propose to make such examination, if we can procure any trustworthy specimens to operate upon,— our own constant occupation preventing the possibility of our personally preparing them, especially at the present season of the year.

As may be gathered from Mr. Young's communication, already quoted, that gentleman kindly favoured us with three specimens of stereographs, printed upon glass by contact with the negatives, illustrative of the several points alluded to in his letter, namely,—the red tone of the picture developed after the removal of the iodide of silver by solution of hyposulphite of soda; the subsequent change to a rich purple by the use of chloride of gold solution — (this change, however, was reasonably to have been anticipated, as we have long been in the habit of availing ourself of it in modifying the colour of transmitted positives in the case of ordinarily developed stereoscopic transparencies); and thirdly, the more agreeable tone of the picture when developed after the removal of the iodide by means of the solution of cyanide of potassium. In this last named case the colour is of a pleasant black or dark grey tone.

We did not apprehend that there would be any use in a microscopical examination of *developed* specimens, so far as our present object is concerned; but, as a mere *matter* of *curiosity*, we did look at them, mounted as they were under a power of about forty diameters, and were so much struck with what we saw that we cannot forbear recording some facts which we feel sure will be of interest to our readers.

In one of the pictures, representing a portion of a rural village, with stream, bridges, trees, cottages, &c., in the foreground, is a pretty extensive kitchen-garden enclosed by a hedge. On a microscopical examination we not only perceived that the hedge is formed of the common thorn, which we can recognise by the form of the leaves, but in one corner of the garden is a bed of raspberry bushes, on the leaves of which we can *distinctly see the veins*. In another part is a post, around which a small cord, carelessly twisted, is visible. In another, the subject being the door of some cathedral, there is a portion of the lower part of a window, which to the unassisted eye presents no appearance of any thing remarkable, but under the microscope the window is shown to be one of stained glass of very elaborate pattern, the whole of the leaden tracery being distinctly perceptible.

Had these minutiæ been discovered only upon negatives, we should have thought but little of the circumstance; but the fact of their transference so perfectly to the transparent positive, tells much in favour of this method of printing our stereoscopic slides, and demonstrates their great superiority over paper impressions.

We are anxious to learn whether these facts of post-fixation developement can render us service in working dry collodionised glass plates in the field: for if the impression in the camera be sufficient for the after developement spoken of, a very slight addition to our working apparatus, when ordinarily using dry plates, would remove one objection that has been made to their employment, viz., the probability of our returning home with a number of insufficiently exposed or over exposed plates. We could easily drop a plate into a suitable vessel containing solution of hyposulphite of soda, which could be prepared on the spot, wash and develope at once in broad daylight, without the incumbrance of a tent, collodion, or nitrate of silver bath; we should then see the result of our labours, before leaving the ground, as effectually as if we had worked with humid collodion. Of course this does not remove the present necessity for the much more protracted exposure requisite with dry plates than with those freshly prepared; but we have some grounds for thinking that even this drawback may

also be removed or materially lessened. It is a subject that we go into *con amore*, and always keep a sharp eye upon any facts bearing upon it.

It will be seen by a letter in another column that the "bottle diaphragm" suggested by Mr. Wm. Ross, of New York, is not quite so useless as it appeared to a previous correspondent. There is, however, a still better arrangement to be adopted in the employment of what has been called by its contriver, the "*pectinate diaphragm*," from its resemblance to a comb. This was introduced by Mr. W. Sykes Ward, a successful amateur photographer, with whom we had some very pleasant conversation at the late *soirée* of the Photographic Society upon this very subject. It can be readily constructed out of a piece of black cardboard, and should be placed *behind* the lens. A circular disk, of the same size as the lens, is cut in halves, and the lower half has a series of teeth cut in it, the form of the teeth being comparatively thick at the bases (which lie towards the circumference), and pointed at the apices, which are towards the diameter, the pointed ends, when in use, being upwards. It is obvious that this kind of diaphragm can be readily applied to either the orthographic or the ordinary landscape combination, in both instances behind the lens, and its effect is, we are assured by Mr. Ward, most beneficial in preventing solarization of skies and similar inconveniences.

We understand that the Blackheath Photographic Society contemplates holding a *soirée* before the close of the season, not in its own suburban district, but in the city of London. It is expected that something out of the common way will be attempted, and from the well-known fame of its President we have no doubt that whatever is undertaken will be carried out with the skill for which he is renowned. We have good reason to know that these gatherings are highly beneficial to the interests of our art, far more so even than appears on the surface.

When an editor presumes to print and publish statements relative to individuals, whose *names* he most unwarrantably inserts, it behoves him, at least, to ascertain whether his assertions coincide with *facts* before giving them circulation. This course, however, appears to be about the last likely to be adopted by a contemporary, whose bad example, as regards nominal designation, we will not follow; nor should we swerve from the course we have for some considerable time pursued, of simply disregarding his *personal discourteous* remarks, but that he, in his last issue, so perverts the truth, that we consider our readers are entitled to a correction of the account given.

Our "titular difficulties" have been already explained; we, therefore, leave that part of the statement (the accuracy of which is only equalled by its courtesy) to find its own refutation.

We have nothing to say in deprecation of our conduct being commented upon, even by one who with his own clasp-knife hacks his own fingers; but when an attack is made upon a gentleman who has long ceased to be responsible for what appears in these pages, we think it right to take up the cudgels on his behalf. Mr. Malone did *not* publish the reports of the Birmingham meetings as asserted, and so far as we are aware did not even apply for them.

We first published these reports, in spite of our antagonist's fruitless efforts to prevent us.

Our antagonist says he *withdrew his objections*; truly he acted with prudence—so did a certain animal when he left the room in disgust, as soon as he saw preparations being made for his expulsion in a less agreeable manner. The remainder of our opponent's *personal favours* we shall treat as usual—with silence.

It appears that photographers are to be favoured with an Architectural View-lens, the construction of which is claimed as a *novelty* by its projector. In this he is much mistaken if we apprehend his description correctly, the late Frederick Scott Archer having several years back employed essentially the same arrangement; and we are in possession of, and constantly work with, a lens of this kind, made by Mr. Archer. The only difference appears to be in the back combination of the so-called new lens being absolutely identical in form with the front one, a change which we cannot regard as an improvement, the posterior focus of the whole triple arrangement being always shorter than its conjugate anterior focus.

The special statement, however, which has induced us to remark upon the subject is the following extraordinary one, viz.—"for instance, if a negative were copied by it, full size, the positive would be *as correct as if it had been obtained by superposition.* The same thing cannot be said with truth of any other lens now in use."

This is a great mistake, and we presume the assertion cannot be intended for literal interpretation, otherwise it would be easy enough to demonstrate that there is no possibility of copying a flat surface upon another plane, by aid of *any* lens with spherical curves, without some error, although by *restricting the extent of field* this may be reduced to an almost inappreciable quantity.

We may also remark that the arrangement does not give a flat field, and that the principle is one we advocated (not invented!) about six months ago.

"Wo is me, that I am constrained to dwell with Mesech and to have my habitation amongst the tents of Kedar."

"I labour for Peace; but when I speak to them thereof, they make them ready to battle."

We trust our readers will excuse the insertion of the following unpleasant but necessary castigation. If those who live in glass houses will throw stones, they will have many panes of glass to pay for.—Ed.

"THOMAS SUTTON, B.A."

The Jersey oracle has again spoken; though not with the same potency, yet with about as much truthfulness in its utterances as there was in those of the ancient Delphic auguries.

The proprietor and editor of a Jersey contemporary has bestowed, for many years, some delicate attentions on the proprietor and editors of this Journal—his remarks and allusions being as uncourteous in style as they have been incorrect and malicious in matter.

In his last number he, in his usual bad taste, referred to the differences as to title existing between the Council of the Photographic Society and myself. I trust the readers of this Journal will pardon the intrusion again of personal matters into its columns, while I reply for the first and last time to the remarks of Mr. Sutton. His continued allusions by name to the various gentlemen who have filled the office of editor to my Journal, compels me, contrary to my own inclination, to return the compliment.

I will take his misstatements *seriatim.*

The Photographic Society's resolution alluded to by him had in fact no reference to my publication. The editors of both the London and Liverpool Journals, notwithstanding our "little troubles,' continue to reciprocate friendly courtesies, and, as will be seen, full reports of the London Society's proceedings appear in these columns.

My reasons for the change of title have already been given, and they will be found to differ very materially from Mr. Sutton's impertinent assumptions. As to my reason for hazarding any interpretation the public might put on the change, that is my business—not Mr. Sutton's. This Journal, with whose rise and *prosperity* I have been identified, is not likely to suffer much from the change of title I thought it right to make—which, after all, was of the most trifling character. Up to the present moment, the Council of the Photographic Society has not obtained the injunction Mr. Sutton announced. I do intend to defend—not my "supposed," but my substantial rights. "The Council has had a disagreeable duty to fulfil, and has acted very"—unwisely, as its members will perhaps find at the proper time.

Amongst his tissue of misstatements it would be strange if Mr. Sutton did not stumble into *one* item of truth—here it is: "The matter, however, is no business of ours!" This is *quite* correct. It is *no* business of his; but, then, like Captain Cuttle, he was bound to make a "note" of it in his publication—his destiny in the conduct of his periodical appears to be to act the part of *Meddlesome*, which, so long as he continues to make himself only simply ridiculous, he may do as long as it pleases himself and his readers.

I have invaded *no* "rights" of the Photographic Society, notwithstanding Captain Cuttle's "note" to the contrary. I have never made any concealment of the place, manner, and description, of my publication, and there is little fear of the public needing a cuckoo "note" from Jersey to keep them right in giving their orders; but I have one consolation — there is no fear on my part of any portion of the public mistaking this Journal for the publication carrying on its title-page the well-known "Thomas Sutton, B.A."

So much for the Photographic Society's "troubles." Now for Mr. Sutton's own "little trouble" in the matter of the proceedings of the Birmingham Society. This censor says, "Why should we not tell *the* story?" The proper and natural reading of the sentence should be with the substitution of the indefinite *(a)* for the definite article. Mr. Malone did *not* apply for the Birmingham Society's proceedings. Duplicate copies of that Society's reports were courteously applied for, *after* Mr. Malone relinquished his editorship, and the request was as courteously refused, on the ground of a compact with Mr. Sutton.

Being refused on such grounds—and believing (as I still believe) that all such arrangements are unwise, injurious to the interests of the art, and contrary to the spirit of the times and of our boasted free press—I took means, as manager of the business department of my Journal, to obtain full and faithful reports of the proceedings and papers of the Birmingham Society; and I trust it will be acknowledged that my reporter has pandered to no improper feeling in his reports, but has given the proceedings impartially and truthfully.

While on this subject I may here mention, that a similar compact entered into with the *Journal of the Photographic Society* has caused the same "difficulty" to arise in my obtaining reports of the Photographic Society of Scotland; and although, through the energy and attention of the gentleman who has reported for me in the northern capital, I have hitherto succeeded in obtaining accurate reports, it will be seen, by a letter in another column, that the narrow views of a section of the Photographic Society of Scotland have prevailed, and the numerous readers of this Journal may in future, possibly, be deprived of the benefit—if they think it such—of these reports. Such a state of things reflects no credit for wisdom on the photographic *illuminati* of the "Modern Athens." It is truly "advancing backwards!"

Returning from this digression, I will again take up Mr. Sutton where I left him in a previous paragraph.

Notwithstanding that gentleman's assertion, I never heard of any "remonstrances" on the part of the Council of the Birmingham Society, nor of any concession on the part of Mr. Sutton. "There *is*, probably, still a field open for good Photographic Journalism;" but I feel certain, judging from the past, that few will cast their eyes towards Jersey for such a literary or scientific phenomenon. As to the competency of the editor of this Journal to provide "original" matter for its columns, I leave it to the readers of the Journal to decide; but I will add, from my own knowledge, notwithstanding that these columns, like some others, do not present the appearance of a "rivulet of print, with a wilderness of margin," more *original* matter has lately been left out than would have sufficed to fill the Jersey print.

I will sum up these observations by a few general remarks.

I believe I can account for Mr. Sutton's frequent and pointed attention to this Journal on other than his alleged ground of competition. Some men have their "bubbly-jock" (as I believe it is termed at Newcastle) — and this Journal has been, and is, Mr. Sutton's "bubbly-jock." It has been for some time his special aversion; and I think the Birmingham affair does not fully account for his consistent hatred.

At an earlier period than the Birmingham "difficulty" alluded to, the large and influential Society at Manchester chose this Journal as its special organ, and sent its proceedings to the neighbouring town of Liverpool, instead of on a voyage of discovery to the other side of the island. The honour was unsought by either the proprietor or editor of this Journal, and, consequently, was more highly appreciated. This step drew from "St. Brelade's Bay" some of those polite private epistles to which the "B.A." of that locality is especially partial.

This I will call reason No. 1.

At a later date, when Mr. Crookes was about to apply for the editorship of the London Journal, I was favoured with a proposal from Jersey that took me certainly by surprise; it was no less than that the then *Liverpool and Manchester Photographic Journal* should be amalgamated (!!) with the *Photographic Notes*, and that Mr. Sutton should become the editor!!! It was promised, as an inducement for me to comply, that, under his editorship, it should be a paragon of exellence in journalism! Having some knowledge and experience of the manner in which such publications should be conducted, and having a lively horror of seeing my Journal made a mere vehicle for puffing off a certain "printing establishment," without a moment's hesitation I emphatically, but "courteously," *declined* the association, and thus saved the photographic world of London from the infliction of Mr. Sutton's presence permanently, as he proposed to take up his residence in the metropolis. Some meed of praise is therefore due to me from the London Photographers for preventing the introduction of the "waters of strife." At that period of his history Mr. Sutton did not profess for the London Photographic Society and its organ the profound respect which he now does.

This is reason No. 2.

From that period to the present Mr. Sutton has consistently pursued his course—not of competition—but of opposition to everybody and everything connected with this Journal. So far did he follow this course as to lay himself open to an action for damages (were it not that the communication containing the libel was one of those eternal *private* missives which this busybody is continually despatching in every direction), by pointed allusions to the position of my Journal—at a time, too, when I would not have taken as much for the mere copyright as would, perhaps, suffice for the purchase of a certain publication, together with the plant of a celebrated "printing establishment" closely allied to it.

I now bring my remarks to a close. Mr. Sutton has no right to outrage the common decorum and decencies of journalism by his impudent remarks on a case as yet untried, and seeking, by prejudging the matter, to give a *false* appearance to circumstances. His toadyism of the London Photographic Society of late — and only of late — has been assiduous; upon that body he has been trying the "honey" process with much earnestness. His late communication to the Society's organ (professedly to show *his* goodwill) looked suspiciously like an advertisement—and a cheap one, too! He is a *universal* genius; he has been great in "dodges" — great in "baths and chemicals"—wonderfully clever in lenses and processes; but he swears principally by alcohol! Pope's couplet *(slightly altered)* might be well applied to him :—

One *process* only will *this* genius fit,
So wide is art, so narrow *Sutton's* wit.

In parting company (I trust for ever) from Mr. Sutton, I would recommend to him what Carlyle calls a "wise silence" in other people's affairs in future.

HENRY GREENWOOD,
PROPRIETOR AND PUBLISHER OF "THE PHOTOGRAPHIC JOURNAL."

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

THE Annual General Meeting of this Society was held on Tuesday, 1st February, 1859 — Sir F. POLLOCK, President, in the chair.

The minutes of the last meeting having been read and confirmed, and seventeen gentlemen elected members of the Society, the following address was delivered by the Chairman :—

Gentlemen, as this is our Annual Meeting, you will have to hear the Report, prepared by the Council, of the progress of the Society, and of all matters that they have thought it necessary to lay before you for your consideration. I am very happy to have hardly any thing but good to report of the past, and I trust, to anticipate of the future. It may be a matter of some regret, that in reference to the finances of the Society, I have to report a slight falling off; but, gentlemen, I have not, like the Chancellor of the Exchequer, in the House of Commons, when he reports a deficit, to propose the laying on of any new taxes. It is not suggested that we need increase our subscription, or enlarge the price of admission to the exhibitions, or to take any other step the tendency of which would be to increase the revenues of this Society; they will (as everybody ought to do) improve themselves — and there are sure signs of such a consummation. The deficit, unfortunately, arises from the failure of (what, I suppose, in this country there is no harm in saying) our commercial speculation, in reference to the exhibitions at South Kensington, and also under the roof where we are now assembled. A proposal was made last year, that this Society should exhibit at the South Kensington Museum — they did so, and the result has been a loss of between £40 and £50; and the exhibitions that subsequently took place in these apartments occasioned another loss of, I think, about £60. We have, however, profited by experience, and do not in the present year exhibit in these rooms — they are out of the way, and though they are convenient enough for the ordinary business

of the Society, they, for some reason or other, are not frequented sufficiently to justify our holding the exhibition here; we have, consequently, as you all know, taken premises elsewhere, and the exhibition appears to present a prospect of very great success. I cannot help observing that upon the opening of the present exhibition there did appear to be a very great increase of manipulative skill, and such as to draw forth the especial praise of His Royal Highness the Prince Consort (whom I had the honour to attend) the day previously to its being opened to the members. His Royal Highness was exceedingly minute in his examination, spoke of the exhibition as being *very* creditable to the Society, and stayed there a longer time than he had done at any previous one. I think I may pronounce the present exhibition one of the best that has ever graced the annals of this Society.

The permanency of our productions is a subject upon which very great attention has been bestowed, and it is an important one, because, no doubt, a very large portion of the claim of the Society to the possession of public utility, arises out of the permanency of the fruit of the labour of its members. Now, if there be any material whatever that can be applied to photography apparently most permanent it is carbon, which, of all substances, seems most indestructible and least liable to decay. It is, according to chemists, antiseptic in the highest degree, and is itself really imperishable. I apprehend, that if a piece of charcoal had been buried in the days of Adam, and dug up yesterday, it would have been found just in the same state as when deposited; and, therefore, we have reason to rejoice at the application of that substance to the purpose of photographic printing. I do not pretend to say any thing about either the process or the inventor, more than that the former is, by some persons, considered an improvement. If it succeed, in all probability it will produce results most acceptable to those, in all classes of society, who regard photographs as permanent records — and I think we may hail it as an advancement in the right direction.

I am sorry to say that the prospect of our being able to "bottle up" light, which I had the honour of suggesting to you last year, has not been realised, and the experiment does not appear to have been repeated by any other person than the celebrated foreigner who communicated it. I understand, that neither Mr. Hardwich nor any other person that I can hear of has repeated it with success: at the same time I think it is perfectly fair to say, that in all probability there has been no misrepresentation on the part of the gentleman who made that communication; and we have reason, I think, to hope, that failure has occurred either from the want of intensity of light, the time in experimenting, or the deficiency of sensitiveness in the paper; in short, that the experiments have not been repeated under circumstances as favourable as those which led to the original discovery.

With respect to our knowledge of light itself, I am unable to report progress of any sort. I am not aware that we have contributed to any discovery that entitles us to declare what light probably is; or to any decisive corroboration of either the theory of Newton, which was that of atoms progressing from the centre of light with great velocity, hence called the corpuscular theory; or of the more generally received undulatory theory. At the Royal Institution I heard recently a very interesting lecture, in which an opinion of Sir Isaac Newton was repeated, that probably light might bear to gaseous bodies a relation similar to that which they bear to fluids, suggesting that all bodies may be capable of assuming a solid, a liquid, and an aëriform state, and possibly a luminous one. Gentlemen, I own we have made no progress in photography which justifies any such notion, or which throws any light upon the subject. I heard the lecture I allude to with the greatest admiration; but I own, that notwithstanding the great and immortal name of Newton, and the admired and respected name of Grove, I could not perceive any grounds for the notion of there being a fourth form of matter, different from, but as it were correlative with, the solid, the fluid, and the aëriform. Gentlemen, I am sure you will forgive me for making these allusions; but, having repeatedly said, that I believe the ultimate labours of photography will be to bring about, if not a perfect theory of light, great advances towards a knowledge of most of its properties, I have thought it right to mention this in connection with the subject, which is, in fact, the fountain of our existence — light to the photographer is like air to animated nature.

I was anxious to say a word or two in reference to what has just now passed before the scientific world, and to state what is my view upon the subject of light. It appears to me, that the effect of light is nothing but the vibration of a fluid of extreme tenuity. We have the example of sound, which is known to be caused by the vibration of the air which we breathe, and light is probably nothing but the vibration of an exceedingly attenuated medium, as much more attenuated possibly as the immense velocity with which it travels exceeds that with which sound progresses. We are able, as a Society, to furnish examples of that which perpetuates art, which encourages science, which promotes all the domestic affections, which records events, and which gives permanence to matters of daily life. I shall be very happy when we have added to these useful purposes any thing that can be called a philosophical addition to the knowledge that we possess of the properties of light.

Gentlemen, we have, as you see to-night, a large increase of members — we have every prospect of our *Journal* being the source of increased income; the Society appears to be progressing in every way: undoubtedly it is becoming more and more useful and advantageous to the public; and I shall be delighted when I can add to all this—that it has contributed one well ascertained scientific fact that shall add one item to the immense mass of philosophy that we now possess.

The Secretary read the report of the Council and the balance sheet, showing the financial position of the Society.

Report of Council.

At the meeting held on this day it is the duty of the Council to present to you their Annual Report upon the state of the Society. It has been customary to connect with that a short review of the progress which the art has made during the year; and happily no anniversary meeting has yet passed away without recording, as the fruit of the year's labour, the acquisition of some new treasure from nature's inexhaustible mine of wealth.

Nor will this year be an exception to the usual rule. We have to congratulate you upon progress made in many of the routes along which photographers are pursuing their researches. In the production of negative pictures, the old wet-collodion process still maintains its pre-eminence. It appears, indeed, to have been but little improved in the theory of its working, but to have become more certain in its results, partly through the increasing care bestowed upon the preparation of materials, partly through the growing experience of its followers.

There are, however, coming into rivalry with it, various modifications of the dry-collodion and albumen processes, which, in addition to their acknowleded superiority in convenience of application, are beginning to dispute the palm with the wet-collodion process in perfection of result. To the truth of this observation, the Society's Exhibitions of the past and of the present year testify most forcibly; nor will it be necessary for you to be referred to the names of those whose efforts in this direction have been most successful, since, doubtless, you have gone along with them in their labours, and shared in the pleasure of their success.

It is, however, for the improvement in the art of printing, that the past year is especially notable. By the general adoption of the alkaline toning and fixing bath, the ordinary chloride-of-silver print has been made both more beautiful and more permanent, while, at the same time, the translation of the photographic original, by transferring it to steel, copper, wood, and the lithographic stone, has been perseveringly studied. Though it cannot as yet be said that any of these methods of carbon-printing have attained such a result as will satisfy their inventors or the public, still the difficulties which beset them are being lessened, and the conditions of success more clearly and more generally understood. A fifth method of printing in carbon, which has lately been brought prominently before you—and which has this especial advantage, that it is, like the silver print, a direct translation of the negative—is perhaps the most valuable acquisition which the art has made during the past year. It rests with the inventor of the process, and those who under his directions are experimenting upon it, that to its undoubted merit of superior solidity it shall add a quality of tone equal to the mellow richness of the silver print.

The increasing interest which the general public feel in the wonders of our art is evident not only from the many new photographic publications of various degrees of merit, of which the past year has witnessed the birth, but also from the frequent notice in the daily and weekly journals of photographic questions, a silent but forcible proof of the growing popularity of the art.

The number of exhibitions and conversaziones in the principal towns of the kingdom, in which the productions of photography have formed the chief element, has never been so great at any former period as during the past months of the current winter season. The commercial applications of the art are rapidly multiplying; and (which cannot but be gratifying to those of its followers who remember the outcry raised against it as a mechanical process) it is at last being discovered that the photographer may employ the pencil of light, not only to delineate crude and literal fact, but to convey a sentiment, to excite the imagination, and set the fancy dreaming.

But leaving the general question of the progress of the art, we come now to the more special business of the evening—the position of affairs of the Photographic Society. Of these the Council regret that they cannot present an entirely satisfactory picture: for, on reference to the financial report, it will be seen that the expenses have been £55 in

excess of the receipts. Of some of the causes of this excess it is not necessary to say more than that they have been removed. The Council and its officers are now alike animated with the earnest desire to work heartily together for the prosperity of the Society; and where there is union there is strength.

The principal cause of the deficit, however, has been the difference of opinion which existed in the Council, and in the Society, as to the proper time and place at which the Annual Exhibition should be held.

It was strongly urged on the one side, that as the Society had provided rooms at a very considerable expense, the Exhibition ought to be held in these rooms, and thus have the advantage of being open at the time when London is most full of visitors, and the weather most favourable to sight-seeing.

Following out this view, the Council did not engage, as usual, the Gallery in Pall Mall, in which had hitherto been held the winter Exhibitions of the Society. This decision was received with much dissatisfaction; for on the other side it was said that the rooms of the Society were not suited for the purpose of an Exhibition, and, though very conveniently situated for the meetings of the members, were not so placed as to be likely to be much frequented by the general public.

It was under the influence of this reaction that the kind offer of the Commissioners of the Kensington Museum, to allow us the gratuitous use of one of their Exhibition rooms was accepted.

Thus were held both a winter and summer Exhibition, each of them resulting in a deficit—the first of £42 5s. 9d., the second of £69 18s. 10d.

If there had been but one Exhibition producing even no surplus of profit, but simply paying its expenses, the balance-sheet would have been satisfactory in its result; it would have shown a surplus of £55.

There is good reason for hoping that the Exhibition of the present year will be of a much more encouraging character.

The management of the Journal has occupied much of the attention of the Council during the past year. With a view of increasing its efficiency they have commenced the publication of a second number in each month during the session of the Society.

It will be seen by the balance-sheet that the Journal accounts present a considerable surplus on the favourable side. It was not with any idea of increasing the funds of the Society that the *Journal of the Photographic Society* was established, but simply that the members of the Society, who, through their distance from town or press of business are unable to attend our meetings, may be kept *au courant* of all that is passing in the photographic world. It has well fulfilled this intention; and it must be gratifying to the Society to find that the strict impartiality with which it is conducted, and the care which is taken by the Council to guard it from ever becoming the medium of unsuitable personal discussions, or the organ for promoting individual interests, have obtained for it the confidence of the general body of photographers to so considerable an extent.

It is the strong wish of the Council to make the rooms in which we meet more useful than they have hitherto been. A commencement has been made towards effecting this result during the past year. Most of the periodicals published here and on the Continent, upon the photographic art, are now to be found upon our table. Others will shortly be added; and it is hoped that, with the aid of the general body of our members, we shall soon have a complete collection of the literature that has reference to our art.

The Society ought also to possess a connected series of specimens of the different forms which the art has assumed since its first creation.

The formation of such a collection is daily becoming more necessary, and at the same time more difficult, as those who were the first to enrol themselves in the photographic army are passing away from amongst us.

Such a collection of specimens of various processes, of records of successive discoveries, would be invaluable for reference, not only for its antiquarian interest, but by its preventing the waste of time and talent which now constantly occurs in the re-discovery of methods long known and for good reasons abandoned.

The materials of such a collection can only be obtained by the contribution of individuals; and to the members of the Society the Council must appeal to aid them in its formation.

It has been already announced in the pages of the Journal, that it is intended to present to each member of the Society, during the current year, a copy of some photographic work approved of by the Council.

To avoid the difficulties which existed in any plan of purchasing photographs for distribution among the members, some of our number have kindly offered to contribute copies of some of their favourite works. It needs, however, still the co-operation of a few more persons before we can be sure of our power of presenting to each member of the Society, during the year 1859, a good photographic picture.

We have now passed in review the principal matters which have affected the Society during the past year. Though the result is of a mixed character, of good and bad fortune, still those who were aware of the difficulties which gathered round us in the early part of the year, and which have been met and overcome, will augur well of the future prosperity and usefulness of the Society.

The Council will continue, as they have hitherto done, to administer the affairs of your Society with the firm conviction that its growth in usefulness is the necessary condition of any increase in its prosperity.

Mr. Bishop remarked upon the auditors' statement of *their* approval of the accounts as uncalled for.

The Chairman—I am not aware whether I quite understand the scope of the member's observations. By "examined and approved," I apprehend that the auditors mean nothing more than that they examined them and found them correct—to have examined them, and nothing more, would have been useless: to approve, without examination, would have been perhaps still worse. I think it merely means, "We, the auditors appointed by the Society, have examined the accounts—that is, we have compared the statements with the vouchers, and find that there has been authority to pay all the bills; and that the receipts appear to be correct." This the individual members of the Society cannot possibly do, and that is the reason why auditors are appointed. It is impossible for this assembled company of gentlemen to go into the accounts. If any one is aware of any thing wrong, or to which it is proper to object, it is competent to him to point out to the Society that real or supposed error; but I am not aware that it is usual to do more upon occasions like the present, than to lay the accounts before the Society; and, in fact, the auditors are the judges selected by the Society to do the duty, which we are bound to suppose they have rightly and correctly performed. It is in consequence of our incapacity or our ignorance that we have appointed persons to perform that office; and they have examined the accounts, and reported that they found them to be correct: they do not mean to say that they approve of the expenditure: they do not mean to say that it is right that any of the money should be spent, but they mean to say—we have examined the accounts and we find that the money has been received, and the money has been expended as the accounts profess it to have been received and expended.

Mr. Bishop suggested, that the very clear views expressed upon a former occasion by the auditor, Mr. Marshall, who went into the subject with enthusiasm on that occasion, and laid down very clear suggestions for their guidance in future, should have been adopted and carried out, in which case every one would have been able to understand the accounts.

The Chairman—It is quite competent at any time—not merely at this annual meeting (for the Society meets much more frequently than once a-year), it is quite competent for any gentleman to give notice that at a subsequent meeting he will move a distinct resolution as to any part of the accounts. The 6th Rule is—

"The Annual General Meeting shall be held on the first Thursday* in February, each year, for the election of officers and council for the year ensuing; for receiving the report of the Council on the state of the Society, and for any other business *of which due notice shall have been given.*"

Mr. P. Le Neve Foster moved the adoption of the Report, which was duly seconded.

A Member recalled to the Chairman his statement to the meeting in March last, as to the proposed new laws, and asked whether any thing had been done with respect to them.

The Chairman—All the information that I can give upon the subject is this, that the laws, although adapted to the embryo state of the Society, were undoubtedly found to be liable to some objection. We were promised that the Council would consider the matter and amend the laws. A committee was appointed and suggestions were made; in the result the Council were not able to adopt any amended laws that were satisfactory, and the matter stands over. We are familiar with that in Courts of Law, where a matter stands over for future consideration; and it is a circumstance which occurs in larger assemblies than the present, having business of great importance. Being unable during the last session to accomplish the object, we shall give it our very best attention on a future occasion.

Mr. Bishop objected to the too sanguine remarks in the Report relative to the Journal, and asked for information whether any Bill in Chancery had been filed against the proprietor of a rival publication?

The Chairman—I believe that a Bill is about to be filed, if it has not actually been filed; but it is right to state in matters of this sort, which are like diplomatic arrangements in another assembly, it may be very prejudicial to the interests of the Society if communications are made pending the progress of a law-suit.

Mr. Bishop inquired, "Who is to pay the piper?" and wanted to know whether the expenses of litigation are to be paid out of the funds of the Society?

The Chairman—Oh! I suppose you would not object to build a bridge from here to the moon at any other person's expense; but

* Now the first *Tuesday*.

if a law-suit is to go on, it must be at the expense of the party for whose benefit it is undertaken.

Mr. Bishop — Then I must ask by whose leave and permission such a step was taken?

The Chairman — By whose what?

Mr. Bishop — By whose leave?

The Chairman — By the authority of the Council.

Mr. Bishop — Then I think they ought to let the members know what they are going to do; because then we can judge whether we are to support them in a litigation of which none can tell the end.

The Chairman — However popular that opinion may be, I think it would be very strange if the Council were compelled to ask the members to enable them to take steps to protect them. It would be analagous to the House of Commons taking steps only by leave of the country, or Ministers taking steps only by leave of the House of Commons. If you have no longer any confidence in your Council, dismiss them. Suppose that some wrong is done, which it is the interest of the Society instantly to redress, by applying to the courts of law immediately, and not to wait for any length of time; and though it may be a question, by-and-bye, for a meeting to say that all this is wrong, yet I think that the Council are perfectly right in doing what they think is for the interest of the Society.

Mr. Hughes complained of the careless manner in which some remarks he had made at a previous meeting were reported in the Journal, and asked who was responsible for the performance of this duty? He objected that the report of what he had said was given in such a manner as to throw ridicule upon him, though his observations had been quite *à propos* to the subject under discussion. He was further dissatisfied, because a letter which he had written in deprecation of this treatment and elucidation of his statements, had not been inserted, and consequently, considered that there was certainly room for improvement.

The Secretary stated that an account of the discussions was prepared from the reporters' notes.

Mr. Malone had a similar complaint to make, viz., that he had been misreported in a very unsatisfactory manner. He considered that this might arise, in some measure, from the undue haste in the publication of the Journal after the meetings, not allowing time for the necessary corrections to be made, particularly when, as was frequently the case, the speakers themselves were the only persons capable of properly amending the reporters' notes. He considered that he had good grounds for his strictures, when he found in the pages of another journal, not the property of the Society, a far better and more accurate report of what took place at the meetings.

Mr. Fenton admitted that he had sometimes winced under the same infliction, for he occasionally found the reports gave as his sentiments something precisely of an opposite meaning to that which he had stated.

Mr. Herve had also a grievance to notice, connected with another department of the Journal — that of the advertisements. He had sent advertisements for insertion in particular numbers, that had been held over from time to time, until his patience was exhausted, and he had now ceased to advertise in it at all.

The Secretary stated that he had nothing whatever to do with the advertisement department, which was entirely in the hands of the publishers. They, in fact, conducted the whole of the business arrangements connected with the Journal.

A considerable amount of further desultory discussion upon this subject ensued, in which Mr. P. L. Neve Foster, Mr. Bishop, and several other members, besides the previous speakers, took part; after which

A Member asked what is the present number of the members?

The Chairman — At the end of the year, 421, which is an increase on those at the termination of the previous year.

Mr. Foster moved the adoption of the report, and the motion having been seconded,

Mr. Bishop moved, as an amendment, that the consideration of the report be adjourned until the next monthly meeting, which was duly seconded, and upon being put to the meeting, negatived.

The original motion was then put and carried.

The officers and new members of Council were then ballotted for, and the following elected:—*President*—Sir F. Pollock, F.R.S., Lord Chief Baron. *Vice-Presidents*—Peter Le Neve Foster, Esq., M.A.; C. B. Vignoles, Esq., F.R.S. *Treasurer*—Alfred Rosling, Esq. *Council*—T. G. Mackinlay, Esq., F.S.A.; C. Thurston Thompson, Esq.; Henry White, Esq.; J. D. Harding. Esq.; N. S. Maskelyne, Esq.; Edward Kater, Esq., F.R.S.; after which

Mr. Bishop, in a complimentary speech, moved a vote of thanks to the Chairman, which was seconded, put, and carried unanimously.

The Chairman expressed a sense of the compliment.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A meeting of the above Society was held at the Literary and Philosophical Society's Rooms, on Wednesday evening, the 2nd instant, Mr. J. Parry in the chair.

The Chairman called the attention of the meeting to the subject of the *Stereoscopic Magazine*, which was intended to be published by the Society and distributed to the members, and invited members to send to the Council, as early as possible, copies of stereoscopic pictures, from which a selection would be made for the publication.

The Secretary, Mr. E. Moon, stated that Mr. J. L. Davies had presented four photographs to the Society's portfolio; these were handed round and much admired for their tone and sharpness.

Upon the suggestion of the Chairman, a vote of thanks was passed to Mr. Davies for his present.

Mr. A. Brothers presented a print, taken by him two years ago; its interest consisted in the colour being retained although it had not undergone the usual process of washing, having been only once rapidly passed through water at the time it was taken, while others printed at the same time, and well washed, had faded.

Mr. Sidebotham read a letter received by him from Mr. Shadbolt respecting the subject of developing by daylight, which Mr. Shadbolt stated he considered to be of great importance, and expressing a wish that the members of the Society would communicate to him further information of the results of their experiments.

Mr. Dorrington explained the satisfactory results of his experience of the raspberry-syrup process; the only difficulty he had to contend with was the extreme tenderness of the film; but he was glad to say that he had now discovered a method by which this could be entirely overcome; he said that he and Mr. Neville had made numerous experiments relative to coating the glass with dilute albumen and other substances, previous to the application of the collodion, and he had at last discovered a plan which was everything that could be desired, rendering the film so firm upon the glass that it would bear any amount of washing without injury, even a water-spout would not remove it. He also thought it would entirely prevent the possibility of blisters in the collodio-albumen process. His plan was to coat the plate with a solution of gelatine in alcohol, and when dry, apply the collodion in the usual way. The solution of gelatine in alcohol, he said, was the same as that recommended by Dr. Hill Norris, the formula of which is given in the number of the *Journal of the Photographic Society*, of the 22nd December, 1856, page 179, and was used by Dr. Hill Norris for coating his dry collodion plates; but he (Mr. Dorrington) thought it more advantageous to use about one-half the quantity of gelatine there stated.

Mr. Sidebotham said he thought Mr. Dorrington's discovery very important; he had tried it with a collodio-albumen plate, and had found it impossible to get blisters. He had also rubbed the glass with his finger previously to the application of the gelatine, and had not been able to observe any trace of the same on developing, he therefore thought this plan would obviate the necessity of cleaning the glasses so carefully.

A general discussion took place upon the subject, the members agreeing that Mr. Dorrington's plan would be exceedingly valuable for all processes.

A number of stereoscopic prints, on glass, taken by Mr. Dorrington, by the raspberry-syrup process, the plates being previously treated with the gelatine solution, were exhibited to the members, and were considered very beautiful, being particularly bright and clear.

A vote of thanks was passed to Mr. Dorrington for his valuable communication.

The prints by Herr Paul Pretsch's process were distributed to the members present. Any member who has not obtained his copy, can have it, by applying at the Society's rooms.

CHORLTON PHOTOGRAPHIC SOCIETY.

The following is given without comment. The proprietor of this Journal feels sensibly the kindness which has prompted the resolution and the official letter which accompanied it. The observations made by the members on the resolution, when proposed, were too flattering to be given here:—

At a meeting of the Chorlton Photographic Society, held at the Chorlton Town Hall, February 9, 1859, it was resolved —

"That this Society highly approves of the change in size and title of the now called *Photographic Journal*, and sympathizes with its Proprietor in the uncalled-for interference on account of changing the name of the Journal to one more worthy of its character."

JOHN HEYWOOD, *Hon. Sec.*

THE PHOTOGRAPHIC SOCIETY OF SCOTLAND.

The usual Monthly meeting was held on Tuesday last, the 8th inst, in George Street Hall. The chair being occupied by Mr. H. Ross.

A few new members were admitted; but our Edinburgh representative was refused admission on the roll of members, under the circumstances detailed in another column.

After our reporter had withdrawn, the Society's Medals for the best two pictures in the Exhibition were awarded to the successful competitors. These were the first medals given by the Society. The medal given for competition amongst the members was awarded to the Rev. T. M. Raven, for his picture (marked No. 216) *Pierrefette: Pyrenees;* and the non-member's medal was given to Mr. Lyndon Smith, of Leeds, for his picture (No. 416) *The Rising Mist.* Both the successful pictures were noticed in our articles on the Exhibition in *The Photographic Journal* of January 1st and 15th.

After this portion of the business had been disposed of, Mr. J. M. Duncan, advocate, read a paper *On the Law of Copyright, as applied to Photographs.*

A gentleman who was present says:—

"This gentleman is not a member of the Society; but they are hard pushed for papers, and are glad to receive them from any *port.*

"It was a terrible infliction to listen to, being a mere repetition of lawyer *slang* or phrases, 'decanted' backwards and forwards, outwards and inwards, upwards and downwards, for the space of one hour, and was nothing when done, leaving the matter as dubious as ever. However, the usual complimentary vote of thanks was given to Mr. Duncan."

Our friend adds:—

"Mr. Tunny, a professional photographer, claims the merit of every discovery brought before the Society, from Archer's collodion process down to the last enumerated by yourselves — '*gin and water.*'"

Exhibition.

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF SCOTLAND.

The Portraits.

Edinburgh, February 8, 1859.

I observe you have very liberally admitted your correspondent "Sel d'Or" space for a pretty long critique on the Scottish Exhibition; but, in my opinion, he has ended where he ought to have begun, viz., with the *Portraits*, for these are the right arm of photography, after all. Where do you get your knowledge of manipulation — your exegetics of photography — but from the plodding, practical, hardworking operator, who has a double stimulant to urge him forward? How is he employed? In taking ten or even twenty landscapes in the course of the year—one this week and another that; or, it may be, half a dozen in April, and then, with a hop-step spring over several months, as many more in August or September, that he may have something for the quidnuncs to chatter about when exhibition time comes round, and get his name emblazoned in the *Journal of the Photographic Society*, or, it may be, embalmed in your own pages. No: it is the professional photographer's daily, hourly employment, to *pose* figures and map faces all the year round; and these are criticised tenfold more sharply by the fair owners than all the landscapes that ever were or ever will be taken. Hence, this is the field for practical discoveries of the excellence of this solution, the economy of that bath, the quickness of who's collodion — in short, every process, as it is developed, is put through the crucible of the professional, from that of Archer's collodion down to the latest discovered. A portrait is also a better criterion of the photographer's knowledge of art than a landscape; because in the latter the forms are fixed, and, if the operator chooses the point from which the subject composes best, and takes his view when the finest effect of light and shade suitable for that particular subject prevails, he cannot fail to give a pleasing transcript thereof. In taking a portrait, however, there is a wide field left open for the artist, who must not allow his sitter to squat down in any position that happens, and then take what he thinks the best view presented by that position; but he must try to adapt the position of the limbs, *pose* the head, and arrange the background, so as to bring out the most pleasing characteristic of each particular sitter, unless he means to rest satisfied with the sixpenny photographer's *pose*, viz., one hand resting upon a table, the other in the lap, with the eyes staring straight towards the camera! He must keep constantly wide awake, seize every circumstantial advantage, and vary his compositions with every new subject as necessity demands.

I quite agree with "Sel d'Or" in placing Mr. Rodger, of St. Andrew's, in the foreground, as regards portraiture. He evidently studies his subject, makes the most of it, seldom failing to bring out a bold and pleasing expression, with all needful accessory details — life in the eye and light in the countenance. No. 41, *Portrait of a Young Lady*, beautifully illustrates this point. No. 113, *Marquis of Bute*, in a graceful, easy, dignified *pose*, which could not fail to please the most fastidious critic. No. 627 is another *Young Lady* by this "Homer" of photography, and is the *acmê* of perfection.

Mr. Moffat sends some heads of well-known citizens — that of H. Ross, Esq. (No. 609), is perhaps the most remarkable as an exquisite likeness, in a graceful, easy, dignified attitude; though I would not be willing to vouch that it had not made acquaintance with the brush, which brings it into the category of painting rather than photography. No. 270, *Rev. Wm. Arnot*, Glasgow, is good; so is No. 272, *Robert Dymock, Esq.*, and No. 273, *Professor Aytoun*, No. 278, *Mr. Alexander Whyte*, is an unmistakeable profile; but none of the thirty-six exhibited by Mr. Moffat are at all to be compared with his portrait of Mr. Ross, which his is *chef d'œuvre.*

Nothing daunted by their former experience, the Messrs. Hay contribute forty-nine specimens, out of which number one might surely expect to gather some precious pearls. No. 266, *Portrait of a Lady and Gentleman*, is bright and sharp, though the gentleman's figure is somewhat stiff and formal. No. 298, another *Lady*, is better. No. 363, *An Officer in Uniform*, and No. 373, *A Naval Officer*, are good pictures, denoting progress; and what especially commends them to me is, that while they are soft and pleasing expressions in commanding attitudes as regards *pose*, they appear to be free from paint—except where that is acknowledged and manifestly visible.

Mr. Scott Elliot bids fair to become as distinguished as Dr. Mark and his forty "little men," whose fame, two years ago, daily stared one in the face in every news-room and newspaper throughout the country. Mr. Elliot's two-and-twenty *old men* are very peculiar and varied in feature — a strange collection, but exquisite studies of physiognomy.

Mr. Farmer's *Portrait of Mrs. Lyon* (No. 556) is quite in the late Mr. Szabo's style. Symoni, too, follows it very closely, introducing into every picture the same stiff, formal, curtain in hard, bold, straight lines—of which Nos. 777, 781, 794, and 811, are fair specimens.

The Messrs. Truefit have in all fifty pictures, only a small portion being portraits. They consist of quaint, humourous scenes illustrating sea-side and out-door amusements, in the Wilkie style, but without the *magic touch* of Wilkie.

Mr. Tunny's frame of portraits (No. 393–401), are not what they might be, and I think he does himself injustice in not sending better, which I am certain he possesses. A critic here "is always reminded when he sees one of Mr. Tunny's pictures of the sublime and dignified *pose* of *Sir John Watson Gordon:*" if this refers to that artist's photograph of Sir John, I would say the key note was too low; and if he refers to Sir John's paintings, it is vastly too high, when applied to the frame exhibited.

Mr. Downie, of St. Andrew's, is a new contributor, and sends twenty-eight specimens, the larger number being portraits, closely imitating Szabo. I am satisfied he has a superior master of the art, as a model, nearer home. Nos. 136 and 138 are fair specimens of this artist's abilities.

Mr. Kibble's portraits, by the collodio-albumen experimental process, are sharp, but hard and inclined to woolliness [see No. 232]. However, he may improve by practice.

Mr. Lamb, of Aberdeen, has some large portraits, which look as if enlarged from smaller ones. I think that in general all efforts at large pictures are unsuccessful, and less pleasing than small ones. The same artist's picture, *Castle Street, Aberdeen* (No. 743), is beautiful; and his view in Pitfodels (No. 77) good.

His co-townsman, Mr. Wilson, has several colored pictures of a smaller type, very tastefully touched. No. 860 is a pure photograph, the gentleman having a book in one hand and an eye-glass carelessly pendant from the other—an exceedingly happy and successful picture, in *pose*, expression, and accessories.

Messrs. Kirk, Truefitt, Smith, Hays, and Miss Taylor, all exhibit pictures on glass—well enough in their way, but to my eye they have a cold, hard, grim, leaden appearance, very different to the paper, which is to them as "wine is to water."

Mr. H. Ritchie's quota is not so voluminous. He exhibits only eight, of which Nos. 82 and 103 are fair examples.

Mr. Ramage sends three, enlarged to life size, which are very

hard and uncouth-looking, but might be greatly improved by being wrought up with chalk or colours.

Mr. Valentine, of Dundee, has a good frame of small portraits of medical gentlemen, neatly mounted in a circle, with apparently the "father of the faculty," much larger than the rest, in the centre. They are hung rather high for minute inspection.

Mr. Taylor exhibits a number of nice "nick nackets," with portraits of glass positives, illustrating the application of photography to lockets, rings, watch-keys, shirt-studs, brooches, &c. These are neatly mounted in gold, and are very suitable for presents to either sex.

Padre Secchi's views of the moon are very interesting subjects, exhibited by Mr. T. B. Johnston.

Mr. Bryson's microscopic photographs of portraits, and various other subjects, are in general favour with the public. When the rooms are full it is requisite to keep a sharp look-out in order to find an opportunity for examining them. No. 740 is a frame with fine microscopic subjects, giving an insect *(Sargus cuprarius)* in its natural size, with compound eye and foot greatly magnified; also a section of *Wangha Cane* and *Exogenous Root*, which form interesting studies to naturalists, by A. J. Macfarlane.

No. 62, by W. H. Bosley, is the only frame regarding which I would be willing to lodge a protest. It contains nine small pictures — good as photographs, but in some degree administering to the prurient taste of fast young men. This class of pictures was severely but very justly criticised recently by one of your contemporaries.

The stereoscopic slides, by Mr. Wilson, of Aberdeen, are what they have ever been, the finest out; and those exhibited now are better toned and printed (by a new method) than any ever previously shown in Scotland. Those of Messrs. Ogle and Edge are fine also, but not equal to Wilson's.

I stop here. I trust you will be able to find room in your next number for these few disjointed remarks on the portraits; and, if you think them worth it, I may have a word on landscapes also on some future occasion. LIMNER.

Letters to a Young Photographer.

No. IV.

My Dear Eusebius,

If you read the last number of this Journal attentively, you will have learned something, not only very curious and interesting to you, but also very important in your present stage of initiation to photography. I refer to the letter of the Paris Correspondent, where the writer describes a box, in which sensitised papers may be kept an indefinite time without becoming either discoloured or deteriorated in their sensibility. This is a real boon to photographers, and one which cannot be too highly commended or appreciated. On dull days, in rainy or foggy weather, when you cannot use your camera, you can busy yourself with making a good stock of sensitised paper, which, preserved from free contact of air and moisture in the magic box of M. Marion, will prove a great convenience as well as a great saving of time and materials. Had I possessed one of these boxes during the great heat of last summer, it would have saved me many pounds; for paper prepared during that hot season would not keep long enough to be printed. I presume, therefore, that you are already supplied with one of these paper-preserving boxes, and that you have a supply of sensitised paper carefully stored within it. You next essay to take a proof from each of the several negatives I have sent you. I suppose it is scarcely necessary for me to tell you how to proceed, as you have seen me perform the operation so many times, and one such inspection will save many pages of description. I will, therefore assume that the negative is within the printing frame; that the sensitised paper is superimposed, and the whole exposed to the light. From time to time you lift one portion of the hinged back of the printing-frame, to see how the proof is getting on. It will be advantageous to you to expose all the negatives to the light at one given moment, so that you may ascertain the relative amount of time each one takes to yield a strong picture; and having ascertained this, to carefully examine that particular negative, noting its colour, density, &c., by comparison with another negative that yields a strong proof more slowly. This comparison must be made thoughtfully and cautiously; for you will soon find, when you come to take negatives, that the great desideratum is just that medium point between density and thinness, if I may so express it, which yields a clear strong proof with a minimum amount of exposure. Most of the negatives that have come under my notice, are what is termed over-developed, that is, the high lights are so dense and opaque that it takes hours instead of minutes for the light to penetrate through them. A good negative is one that will yield a strong proof in ten or fifteen minutes in a tolerably clear day. In an over-developed negative, the contrast of chiaroscuro is too abrupt and harsh, the half tones are lost, and a heavy blotty picture is the result. Therefore, I repeat, examine well that negative which yields a *good* proof in the shortest space of time during which it is exposed to the light. The sensitised paper should be cut a little larger than the glass of the negative; the projecting margin will become dark much sooner than that portion of the paper under the picture. When it has become of a deep chocolate colour, and exhibits a prismatic array of colours on the margin, or what from its appearance is termed bronzing, you may conclude that your picture is getting on, that is, if the negative be not too dense. I like to print the proofs pretty strong. The intensity, if too great, may be reduced in the toning and fixing operations.

I will now suppose your proofs printed, and that you are about to proceed to toning and fixing them. If you cannot attend to that operation immediately, place the proofs in the air-tight box until you are ready.

Now, as to toning and fixing, these two operations may be performed in one bath, or they may be done separately. Mr. Hardwich's formula, as given in his *Photographic Chemistry*, is the one most generally in use during the last year or two; and it is doubtless a very excellent one in the hands of a photographer well acquainted with chemical philosophy; but in the hands of a beginner, its results are likely soon to become uncertain. It requires no inconsiderable amount of experience and discrimination to recognise that state of chemical change which has been aptly described as "a state of tottering equilibrium," and you will have to work your way up to it by patient study and constant practice.

The almost universal condition of "fading away" exhibited by photographic proofs, has led to the suggestion of alkaline toning baths, and various formulæ have been proposed of late, with a view of getting rid of the dangers attendant upon an acid condition of the bath, composed according to Mr. Hardwich's formula alluded to above. This chemist has himself proposed a new formula, which you will find on page 4 of this Journal. This formula, when properly attended to, answers very well. I have lately tried one recommended in the Paris Correspondent's Letter in page 11. This formula is the suggestion of M. Bayard, a very eminent photographer. I am well pleased with the results it gives; in fact, like it so well, that I shall probably continue to employ it until a better one is proposed. It gives very rich violet tones, and preserves the whites pure.

Whatever be the composition of the bath employed, the toning agent is generally chloride of gold, and the fixing agent hyposulphite of soda. I say generally, because good results can be obtained without the employment of these agents, and such as cannot be distinguished from those produced by them; but as the use of the substitutes demands a high degree of care and skill, I shall defer communicating the process until you are further advanced in the philosophy of our art.

Before I quit this part of my subject, I may call your attention to M. Le Gray's formula for a toning and fixing process, which you will find on page 39, in the Paris Letter. This I have also tried, and found it very good, but as it is much more troublesome than M. Bayard's, I have not adopted it.

I do not now speak of other methods of printing than those dependent upon the employment of the salts of silver, because they have not yet attained to a degree of excellence that can compare with the latter. It is not at all improbable, however, that a more economical process than that requiring the argentine salts may be perfected sooner or later, and I, for one, pray for the *sooner*.

If you will come to town next week I will assist you in selecting a camera, &c.—Yours, &c.

Photographic Glossary.

Daguerreotype — A heliographic process in which direct positive pictures are obtained upon silvered metallic plates; it is the invention of M. Daguerre. By exposing the silver plate to the vapour of iodine and bromine, a sensitive film of bromo-iodide of silver is formed. After exposure in the camera, the image is developed by the vapour of mercury; the iodide is then washed off with hyposulphite of soda, and the image is fixed by chloride of gold.

Dammar Resin — A white friable resin imported from Java, Borneo, Sumatra *(Dammar Orientalis)*, Australia *(Dammar Australis)*, and other places. It is used as a substitute for mastic in making picture varnish. Although frequently recommended for making a photographic varnish for negatives, it is not adapted for that purpose on account of its brittleness.

Decolouration — The depriving of colour. The solution of nitrate of silver used for sensitising albumenised paper is apt to acquire a deep blood-red colour, owing to a portion of albumen becoming dissolved in it. Various substances have been proposed as decolourisers, such as animal charcoal, pipe-clay, kaolin, and fuller's earth, but the best is a weak solution of chloride of sodium. *Vide* page 33.

Developement — This term is applied to the process of 'bringing out' the latent photographic image, after the sensitive surface has been impressed by the action of light in the camera. A printing process, dependant upon analogous principles, is called printing by developement.

Developing Agents — In the Daguerreotype process the developing agent is mercury in a state of vapour. In the collodion process the agent usually employed is pyrogallic acid; gallic acid is also a general developing agent in the albumen, waxed-paper, and also in the collodion processes. The salts of iron are important developing agents.

Dextrine — This substance, sometimes called 'British gum,' is roasted starch, which by the action of heat acquires new properties, becoming soluble in hot and cold water, and losing its gelatinous quality. Its name is due to the property it possesses when acted upon by polarised light of turning the plane of polarisation to the right. Dextrine may be obtained by the long continued action of acidulated water at high temperature upon starch, and also by the action of diastase. It is a useful substitute for gum-arabic, and is extensively employed in 'gumming' postage stamps.

Diaphragm — Diaphragms are pieces of brass, &c. perforated with holes of given diameters, placed in front or between compound lenses, to cut off the superfluous rays of light, and to produce greater intensity of the image as well as to correct aberration.

Diapositive — A diapositive picture is a positive picture intended to be viewed by transmitted light or as a transparency.

Dipper — A simple piece of apparatus for holding the glass plate while it is dipped in the nitrate of silver bath. It may be made of silver wire suitably bent, or of a strip of plate glass, with a cross piece cemented at the bottom to prevent the glass plate from slipping off.

Distortion—When the image produced on the focussing screen is not an exact counterpart of the object in respect to proportion, it is said to be distorted. It is difficult to construct a lens that shall yield an image free from distortion, owing to the spherical aberration inherent to their spherical form. The greatest skill of the optician is directed to the attainment of that object.

Double Iodide —A strong solution of iodide of potassium is capable of dissolving a minute quantity of iodide of potassium; the mixture is termed the double iodide of silver and potassium. It is used in the calotype process.

Diactinic — A transparent body, such as blue or white glass, which allows the actinic or chemical rays to pass through it, is said to be *diactinic*. For a lens, diactinic is a better term than achromatic. Yellow glass is *adiactinic*, as it is opaque to the chemical rays.

New Books.

A Manual of Photographic Chemistry. By T. F. Hardwich, Lecturer on Photography in King's College, London, &c. Fifth Edition.

(John Churchill, New Burlington Street.)

There is a good story that has often been told, of an antiquary who possessed a pocket-knife upon which he set great store, because it had been presented by Charles II., upon some memorable occasion, to one of the enthusiastic and credulous archæologist's ancestors. The knife was always carried about with him, was in constant use, and paraded upon every possible occasion — indeed, many a remarkable incident was connected by tradition with the knife, which had quite a little history of its own existence; amongst other things, of course, the exact date of the addition of a rivet, a new blade at such a time, a new handle at another — so that on reckoning them up, it was found that there had been forty-two new blades and fifteen new handles!

Now, we do not mean to say that the identity of Mr. Hardwich's fifth edition of his manual with the first, is quite so problematical as was the case with the antiquary's knife; yet the two, when compared, bear some such relation to one another as the promising lad to the well-developed intelligent man. We find that there are upwards of 120 additional pages as compared with the fourth edition; but this alone is not a measure of the new matter, as a considerable quantity more has been substituted for that which has become obsolete, in consequence of our increased knowledge of various facts and better comprehension of the phenomena connected with the practice of the art.

We know of no more conscientious guide than Mr. Hardwich, who is indefatigable in examining, collecting, and comparing stray scraps of knowledge, besides all the more important facts in any way bearing upon the scientific branch of photography — nor is he less active in putting to the test of actual experiment the various practical suggestions which he meets with, provided they offer even the probability (not to say possibility) of improvement. This in itself is no trifling qualification for a teacher, and must entail upon him an amount of labour infinitely greater than most persons are aware of. From his position as lecturer at King's College he naturally comes in contact with a large number of devotees to the photographic passion, all the more enthusiastic and eager in consequence of the intoxicating influence (if we may use such a term) that is usually experienced by all, who for the first time find they can produce a presentable picture.

One of the pre-eminent qualifications of a teacher is his own aptitude for learning and utilising the knowledge of others — and this qualification Mr. Hardwich possesses in a very considerable degree; hence it is that in each succeeding edition of his work, we not only obtain the benefit of the author's own contributions, which are large, but also the labours of other willing workers in the field of photographic research, and these refined from the previously adherent dross, being subsequently sifted and examined by the experimental tests dictated by the skill and acuteness of such an accomplished operator as this gentleman has proved himself to be.

In the present edition, amongst the alterations and additions, we find particulars, given in a popular style, of all the new forms of photographic lenses introduced into use during the past two years.

One of the most important novelties will be found in Chapter VI., on the production of pyroxyline, and on the chemistry of the nitrate bath; to those who make the production of collodion a matter of business, the mass of valuable information (we had almost said *in*valuable) contained in pages 95 to 110, will repay them many times the whole cost of the book, while to every photographer it is satisfactory to know how to do this work properly, even if he prefers to perform the operation by deputy.

In the pages we have quoted, the author has freely published the experience he has gained during the past two years in manufacturing collodion, not upon a small scale, but what is much more difficult to do with any thing like uniformity of result, in very large quantities, many hundreds of gallons having been prepared by him; and this fact of the increased difficulty of operating upon a large scale will be acknowledged by every maker of collodion.

There is new and valuable information relative to the production of collodion positives upon glass, as also with reference to the correct application of different developing agents, and the circumstances under which each is most useful.

A few pages are devoted to the various modes of paper printing, by aid of bichromate of potash and the organic and other substances lately associated with it, in order to avoid the use of silver salts.

There are hints on the construction of glass operating rooms, on taking instantaneous pictures, and some very useful ones on photography in hot climates, including advice upon packing apparatus and chemicals for long journeys.

In Chapter III. of Part II, we have the excellent method of toning, by alkaline chloride of gold, recently given in a paper by the author at the Photographic Society; and Chapter V. of the same part contains particulars of several preservative processes, amongst which that with collodio-albumenised plates finds most favour, and elaborate details are given for practising the same.

The above are mere indications of the good things to be found in Mr. Hardwich's *Manual*; and it is not too much to affirm, that no professional operator or amateur, desirous of pursuing the scientific branch of photography, can *afford* to go without a copy of the work in its present form.

Practical Photography on Glass and Paper. By Charles A. Long. Third Edition.

(Bland and Co., 153, Fleet Street.)

There is, perhaps, no greater proof of the general and increasing spread of the photographic *furor* than is evinced in the publication of a large number of elementary manuals, some of them extending to several editions.

It will not be necessary for us to enter particularly into any detailed description of the contents of the present work, seeing that as this is the

fourth edition the public must already be pretty well acquainted with it; we may, however, remark, that a chapter upon "colouring positives upon glass" has been added on the present occasion.

We regret to notice, that the system of toning paper positives by means of the old hyposulphite of soda bath—a system now almost exploded —is still recommended. This will probably make way for more recent improvements in the next edition; when we hope, also, to see the acetic acid left out of the chloride paper sensitising bath.

Of course, there are many points to which a practised manipulutor might object; but *manuals* are not intended for skilled operators, and certainly the novice will find much in this pamphlet that will be of service in initiating him into the mysteries of the "dark room," and the mode of conducting photographic incantations.

Foreign Correspondence.

Paris, February 10, 1859.

THE beautiful specimen of Herr Pretsch's photolithographic process, presented with the last number of your *Photographic Journal*, has excited a most vivid interest and intense curiosity among our photographic *savants*. I regret that you did not forward to your agent a larger supply of copies; I was literally besieged for mine, and could have sold it many hundred times over for what would have produced thrice its weight in gold. The one topic in photographic *salons* and *ateliers* is now "photographic engraving;" and although new processes are announced daily, "the cry is still they come." Photographers must consider themselves under great obligations to your enterprise and liberality, in thus providing them with so interesting a specimen of the applicablity of photography to book-illustration, &c.

Apropos of this subject, a communication from M. Jobard, made to the *Acadèmie des Sciences* so long ago as 1840, but only now divulged, of a method invented by him for obtaining lithographic impressions from heliographic images. As the process is very ingenious I shall quote it *verbatim*. He says, "In my first experiments with the daguerreotype, which art I introduced into Belgium, I recognised the possibility of lithographing heliographic images, by exposing a stone or plate of zinc coated with iodine. Being myself a lithographer, it was natural that it should occur to me among the first. The stone or zinc plate, instead of being developed by exposure to the vapour of mercury, must be immediately covered with a thick solution of gum-arabic, blackened with lampblack, and put away in the dark until the gum water becomes dry. The stone is then plunged into a bath of water to dissolve the gum, and washed. It is next placed on the printing press, and an inked roller passed over it. The portions of iodine which have been decomposed by the light are found to have been removed by the gum which has been placed upon it, which has, in fact, *prepared the stone* for printing from, that is to say, has communicated to it the property of repulsing the particles of oily ink, but which are attracted, and attach themselves to, the portions in which the iodine is undecomposed, whether the iodine be allowed to is remain or removed with a soft sponge. In this way we may obtain proofs perfect in every part, with the whites quite pure; but this is a very delicate operation, and can only be successfully performed by a very skilful lithographer. The zinc plate is treated in exactly the same way as the stone. The main point in obtaining a successful result consists in applying as little ink as possible to the roller." M. Jobard has kept his secret nearly twenty years, but with what motive it is not easy to divine, as his process is ingenious, and has not been anticipated entirely by others.

Like the other sciences, photography has its martyrs. I will relate the tragic fate of one who fell a martyr to photographic engraving. Whoever has moved within the magic circle of Art in this city, must have encountered one of its noblest and most devoted enthusiasts in Hurleman, the engraver with a wooden leg. How he gained this member history sayeth not; but neither he nor his friends would have parted with it, nor exchanged it for a better on any account. There was a wonderful power of expression in that amorphous wooden leg: it was the index of his feelings and emotions, the confidant and interpreter of his thoughts. It imparted a supernatural eloquence to the music of his steps. Was he happy? It rattled along the pavement in bounding steps, expressing the joy of the owner's heart in all sorts of fantastic curves and quirks. Was he sad or melancholy? Then it came upon the ear like the solemn sepulchral tread of the statue-ghost in Don Giovanni. Unfortunately, the latter phase was too often apparent: Hurleman was poor, miserably poor, in this world's goods, but rich, unspeakably rich, in genius and devotion to his art. He had one bosom friend as poor and as rich as himself—one Carl Muller, a true genius, but who fell an early victim to the assaults of poverty. Hurleman never truly felt his poverty excepting when it stood in the way of his enjoying good books and the treasures of the world of art, or the pleasures usually indulged in by artists. Gratuitous exhibitions were never missed by him; but only those that attacked his purse. As an engraver his talent was truly remarkable; no less so was his skill and delicacy of handling. In the manipulation of his art he had no equal; while the fertility of his inventive resources was unlimited. When, in 1846, photographic engraving engaged the attention of the learned, to whom should they so naturally apply as to poor Hurleman? Great was his delight when he received from M. Fizeau the commission of engraving a daguerreotype plate, with the congratulations of his friends upon his success in his delicate task. But when the *Acadèmie* decided upon intrusting M. Fizeau with the engraving of an important series of daguerrian plates, with a view of encouraging similar researches, and of giving the artist some testimony of the interest his labours had excited, then Hurleman's joy knew no bounds. On the day when Hurleman left the sitting of the *Acadèmie* charged with this important commission, he was like one demented. He could not remain in one place two minutes at a time, but rushed from one quarter of the city to another to announce his good fortune to his friends and to purchase materials. Then, truly, the wooden leg appeared to perform St. Vitus's dance; nothing else could describe its eccentric gyrations. It is supposed that he must have travelled on his unequal members some thirty miles in the latter half of the day. This was more than his frail nature could endure. Under a weight of fatigue, care and anxiety, he mounted to the top of the lofty staircase leading to his humble lodgings, and throwing himself exhausted on his bed, was soon attacked by typhus fever, and in a couple of days breathed his last sigh upon the bosom of his wife, with his only child, a son, clinging piteously to his side. The cemetery of Mount Parnassus was near by, and there they made his grave. But the tragedy was not yet concluded: his poor, loving wife, exhausted with the terrible woe and grief that had so suddenly fallen upon her, succumbed, in her turn, to the stroke of the disease. She sank into the bed from which the cold corpse of her husband had just been removed, with the conviction that her last hour had arrived. To the entreaties that she should be removed to a hospital, her reply was,—"No! let me die here, where he died!" On the following day she was interred by the side of her lost husband, and the same funereal cypress waves over their graves. In the room, so lately redolent with their humble joys and happiness, there remained, stupified with grief, their orphan son.

Hurleman was beloved by many who would have flown to his side at the first hour of his illness, had they known of it, but this sad drama was enacted only in the presence of the performers themselves. On the day succeeding the catastrophe, my friend Baldus thought he would call upon the poor engraver, to see how he was getting on with his work. He mounted up to the sixth storey and gaily jerked the bell. But in vain, no response! He continued to ring, until an old woman, who occupied a neighbouring apartment, attracted by the noise, came to offer an explanation, leading the little orphan by the hand. A few words explained all the sad story, and she opened the door of the deserted apartment. It was nearly empty: the poor artist had been obliged to part with every thing to sustain his family, save one — an engraving after Raffaelle's *Madonna*, which his poor friend Muller had given to him with his latest breath. M. Baldus took away this engraving, and made up a little lottery to dispose of it, by which means he raised a sum sufficient to bind the orphan apprentice to M. Lerebours, the optician.

Correspondence.

BOTTLE DIAPHRAGM.

To the EDITOR.

SIR,—Having tried the form of aperture in the diaphragm of a lens for landscapes, mentioned by Wm. Ross in your valuable *Journal*, I beg to state that the effect produced is a beautiful clearness over the whole picture. By placing the diaphragm within the lens, instead of externally, still greater clearness is, in my opinion, thus produced.

I am, yours, &c.

January 2, 1859. DAWSON CAMPBELL.

CLOSE PHOTOGRAPHIC SOCIETIES.

THE PRESS EXCLUDED.

To the Editor.

Sir,—As correspondent of your Journal from Edinburgh, I request a little space to make public the proceedings of the Photographic Society of Scotland, in connection with my presence at their monthly meetings —proceedings which I consider to be at variance with liberal and open conduct, and not calculated, by any means, to raise that Society in the estimation of the scientific public. The facts are briefly these —

Being requested by the publisher of your Journal to send up reports of the papers read at the meetings of the Photographic Society here, I attended the last meeting of the season, held in July, and that in November when the new session commenced; I took short-hand notes of the proceedings, which I transcribed in an abridged form, and duly forwarded to you for publication. At the close of the November meeting I was questioned by the Secretary as to the capacity in which I attended the meetings, and informed that gentleman that I was there as reporter for an Edinburgh newspaper and also for your Journal. The Secretary thereupon explained to me that he would be only too happy to see me present in the former capacity, but that in consequence of a special arrangement which the Society had entered into with the *Journal of the Photographic Society*, the presence of a reporter for another photographic newspaper was contrary to the wishes of the members generally. The arrangement alluded to he stated to be as follows:—that the *Journal of the Photographic Society* had agreed, in return for an *exclusive* and official report of the Society's proceedings furnished to their paper, to supply the members of the Society with copies of the Journal at prime cost or at a reduced rate. He went on to state, that if my presence at the meeting was under the sanction of the managers of the *Journal of the Photographic Society*, the Society would not object to my taking notes, but as matters stood, the presence of any reporter for a rival journal was objected to.

In a few days after the November meeting, I called upon the Secretary at his office, and after a lengthy conversation, requested that he would insert my name on the business circular for the December meeting of the Society as a candidate for admission as a member, in which character I considered I would have an undeniable right to take notes of whatever transpired at the meetings. This course, Sir, appeared to me to be my only alternative, after hearing, personally, the opinions of the Secretary. Through some informalities, my name was not inserted in the circulars either of the December or January meetings, but it appeared in the programme of the last meeting held on Tuesday. I thought it my duty to attend that meeting to see how matters turned, and the result I will briefly narrate. In answer to a question by a member, as to how my presence would affect the special arrangement with the London Journal, the Secretary, after reviewing the circumstances of the case, and the conversation which passed between us, intimated, that if the Society did not adhere to the arrangement with the London people, the copies of the Journal would of course not be supplied at the reduced rate in future, and moreover, the Society would not have acted in an honourable manner with the other parties to the agreement. A discussion afterwards ensued, and the result of the ballot was, that twenty-three black balls were thrown in against my admission to the Society, and two white ones in my favour. The President, in acquainting me with this condition of things, gave me an assurance, on the part of the Society, that in proceeding as they had done, the members acted solely on the principle of the aforesaid agreement, without any consideration whatever of a personal nature.

This exclusion from the Society I consider to be both unfair and impolitic. In the first place, I will venture to assert that there are many members who, up till the last meeting of the Society, were entirely ignorant of the agreement referred to. That all persons joining the Society should, without intimation of any kind, be bound down under an arrangement of which they know nothing, appears to me to be a system of secret tyranny. Why should not the members of a society — formed for the purpose of forwarding a certain art — have the privilege of taking whatever notes they please in their private capacity, and transmitting them to any quarter? Are they to be prohibited from exercising this right? If so, it is manifest injustice. If an arrangement such as this really exists, why is there no mention of it in the Society's laws, so that members joining may fully understand, before sending in their names, the peculiar conditions under which they attach themselves to the Society. Several gentlemen on Tuesday evening expressed themselves strongly against a reporter being allowed to take *verbatim* notes of every paper read at their meetings; upon which I thought it well to state openly that such was not my intention, and would not be my practice if admitted on the roll, and that I should restrict myself to sending condensed notices — though not limiting them to any specified extent— of the business that transpired. Now, how is it that the Society has so strong an objection to any report sent up to other than their patron journal? Simply because they receive copies of the paper "at a reduced rate." For a few pence, then, saved per week or fortnight, here is a leading scientific society placing itself, body and spirit, under the sway and guidance of the organ of a distinct association, located four hundred miles away. Do they gain by it? Yes, assuredly, by the pence in question. Is there any sacrifice to the "filthy lucre?" is there any loss of independent action? I leave you, sir, to judge — I leave you to weigh in the scale, against the coppers, the result of this mean motive, for the exclusion of the public press. But it is an agreement, and it would be dishonourable to break through it! Is it, I ask, an agreement on any real solid principle? By no means. The Society send their papers to one public scientific journal. Is not publicity a benefit to all well-organised associations? The Society admits this, by the very fact of sacrificing so much to print. In what respect, then, would the Society not gain by wider publicity? Really the Photographic Society of Scotland must have been (to use a popular phrase) "bamboozled" by their friends in London — their ingenuousness must have been largely imposed upon. Surely it would be more honourable to cancel so absurd an arrangement than to preserve it — more advantageous to the science they seek to make known — more just to themselves as a society, if scarely so profitable as otherwise to their pockets. As it is, the mysterious agreement comes to an end on the 1st proximo. May I ask the obliging Secretary whether the interesting event will be recorded on the minutes, or endorsed on the back of the *parchment certificate of compact*, so that the hundred or more members may have some idea of the approaching crisis? That it is an important event who can doubt? The Secretary himself took the trouble to inform the forty or fifty gentlemen present on Tuesday night, that by the arrangement no less a sum than *Twelve Shillings per annum* was saved to each of them. Undoubtedly these worthy gentlemen never before supposed that their balance sheets were so largely affected by their membership. Were it not for distressing the Secretary, I think, sir, I could show that the twelve shillings is a shilling or two *beyond* the mark. Perhaps the Society will, after March, raise its terms with the *Journal of the Photographic Society*, and get the cost per copy of that paper further lowered by one penny or twopence. What an immense influx of members would the Society then experience! Why, sir, it would surely induce some thirty out of the forty professional photographers of Edinburgh to join it, instead of the miserable, but "dauntless *three*," who at present represent the profession in "Modern Athens" on the Society's roll. It may possibly be *principle* which keeps these thirty-seven professional gentlemen aloof from the Society—not principle on *their* part, sir, but on the part of the Society; for, if you recollect, it was principle that induced the "committee of bachelors," last year, to discard Rejlander's glorious work, *The Two Ways of Life*, which would have carried everything before it in any exhibition, and set up in its stead—strictly on *principle*, mind—a *nude* Niobe, who, assuredly, must have been "all tears" on the occasion!

Now, sir, I do not intend to take up space by recounting how the matter of my exclusion has been "worked" by the Secretary, or by noticing the preliminary "meetings of council" to get up the brief for the prosecution—these immense efforts being so well represented in the attendance on Tuesday night, which was much larger than usual. I am content to believe that the black clique of "twenty-three" is only the majority of a meeting, and not of a Society. The members could not have objected to my admission on the ground of not being a professional photographer or an amateur; for, like many other members who have never divided the Society in submitting their names as candidates for entrance, I am simply an "admirer of the art." I do not know, sir, what the rules in such questions are with other kindred societies; but I am bold to affirm, that few would adopt the course which the Scottish Photographic Society has taken in this instance. The society is "close" and exclusive—beyond the periodical "paragraphs" they forward to local journals here, and beyond the lengthy MS. they forward monthly to their fostering mother,— *The Journal of the Photographic Society*. Members must not take notes and use them at discretion — or at *indiscretion* — on pain of blackballs and exclusion!

Let the scientific public, then, shun an association which is dependent and so excessively "honourable" to its agreements; for it never can, while existing under the trammels of an opposition society, and working under such mean conditions — conditions too mean to figure in the laws and regulations — secure that respect to which otherwise its eminent position might lay claim.— I am, yours, &c. P. M. F.

Edinburgh, February 8, 1859.

[We think our correspondent errs in his selection of the vulnerable point:— the Society has made a *defensive* treaty; there is no reason why it should also be *offensive*. — Ed.]

HONEY PROCESS, &c.

To the Editor.

Sir,—I am extremely obliged to you for the kind way you have helped me out of numerous difficulties. The only way I have of showing my gratitude to you, is in advocating your very ably written and valuable Journal to my friends, both amateur and professional, which I do with my utmost power. I have met, I am sorry to say, with some failures in your simple and beautiful honey process which has succeeded so well in other hands. I find, on developing, that the picture acquires a disagreeable *red* tone, and is covered with minute holes. I do not know where to find a detailed account of the process, which would remedy the evil complained of, and give me some idea of the length of exposure required in comparison with the humid collodion process. There is an account of your process in Mr. Sparling's book, in "*Orr's Circles*," succeeded by a paper on the same subject, by Dr. Mansell, of Guernsey, which I suppose you know. Do you consider his modification of your process as good as the original?

Accept my apology for trespassing on your time, and, with sincere thanks, believe me to be yours, &c., ELY.

P.S.—Will you also please to tell me how I could get sufficient intensity with iron developer.

[We thank you heartily for your kind expressions.

The red tone in the negative is rather an indication of over-exposure. If the collodion be suitable, that is, moderately *old* and spongy in structure, and the syrup well filtered, you ought not to have the minute holes. Dr. Mansell's modifications are good, especially the use of steam before developing, and the pictures taken by that gentleman bear undeniable evidence of his success.

For *ordinary* dry plates we prefer Dr. Norris's or collodio-albumen, that is, if we have to prepare for use at an *indefinite time;* but if for use the following day, we still stick to our old *sticky mess,* as we have seen it designated. For interiors we know it to be first-rate, better even than wet collodion.

We find that, at this season of the year, the iron developing solution recommended by Mr. Hardwich is also good for syruped collodion, viz., distilled water six and a-half drachms, Beaufoy's acetic acid one and a-half drachms, protosulphate of iron fifteen grains—dissolve; then add acetate of soda ten grains. After exposure (lens fourteen inches focus, aperture five-eighths of an inch) for four minutes, steam the plate by holding it over a dish of hot water, then pour on the above-named developer; the image will appear rather slowly and very likely in patches, but this is of no consequence; keep the solution gently flowing backwards and forwards until the whole is *evenly* developed, and as soon as this has come about, *immediately* wash away the iron solution, no matter how weak the picture may be. Fix with hyposulphite of soda, wash well with common water, drain slightly, and then wash with a *few ounces of distilled water*, again drain, and pour on some of the following, namely, distilled water one ounce, pyrogallic acid two grains, citric acid one grain, to which you must add about twenty drops of pure solution of nitrate of silver (about thirty grains to the ounce), but *not that which has previously been used for baths* or any other purpose.

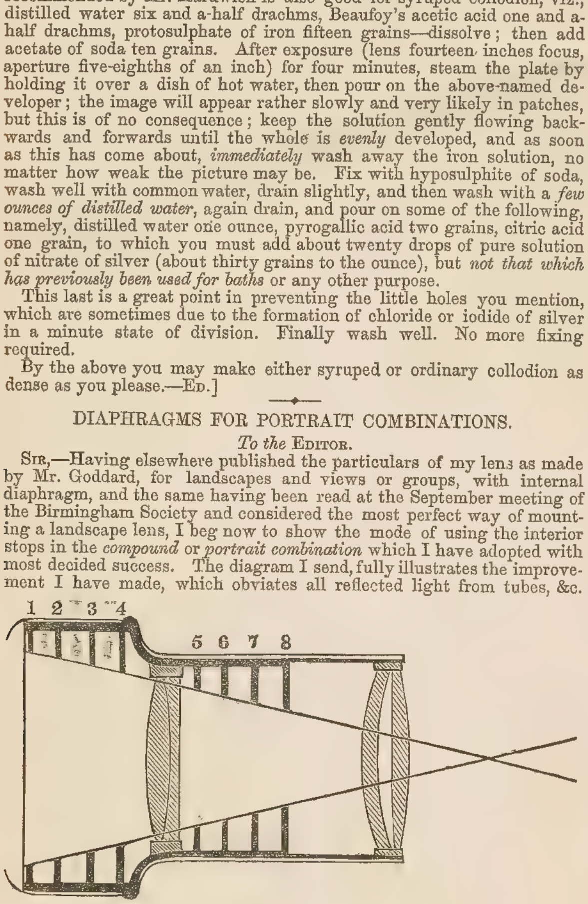
This last is a great point in preventing the little holes you mention, which are sometimes due to the formation of chloride or iodide of silver in a minute state of division. Finally wash well. No more fixing required.

By the above you may make either syruped or ordinary collodion as dense as you please.—Ed.]

DIAPHRAGMS FOR PORTRAIT COMBINATIONS.

To the Editor.

Sir,—Having elsewhere published the particulars of my lens as made by Mr. Goddard, for landscapes and views or groups, with internal diaphragm, and the same having been read at the September meeting of the Birmingham Society and considered the most perfect way of mounting a landscape lens, I beg now to show the mode of using the interior stops in the *compound* or *portrait combination* which I have adopted with most decided success. The diagram I send, fully illustrates the improvement I have made, which obviates all reflected light from tubes, &c.



The figure shows the stops as Nos. 1, 2, 3, 4, in the funnel or projecting front, 5, 6, 7 in the tube, and 8 the central diaphragm, which for $3\frac{1}{4}$ lenses may be $2\frac{1}{4}$ without any loss of active light or of definition, which will be greatly assisted by the whole. All false glare will be removed, and any one may easily make the addition with cardboard, well blackened; it can be made to draw out, a tube being constructed of cardboard first, then the stops fixed in by rings of cardboard glued between each, which holds them fast in.—I am yours, &c.

69, Blenheim Street, Newcastle-on-Tyne. JOHN BROWN.

For a $3\frac{1}{4}$ lens No.	5, is $2\frac{3}{4}$ in opening.	The front,	or No.	4,	is $3\frac{1}{4}$	in opening
„	„	6, „ $2\frac{1}{2}$	„	„	„	3, „ $3\frac{3}{4}$	„
„	„	7, „ $2\frac{1}{4}$	„	„	„	2, „ 4	„

AN OPEN QUESTION.

To the Editor.

Dear Sir,—I think that if the Photographic Society has another exhibition next year there should be some arrangement so as to evince an aim beyond mere show and sale. Classify and specify, if you like, and keep each class in a separate division or compartment. For instance:—

1. Portraits.
2. Sea and landscapes.
3. Architecture.
4. Still life representations.
5. Scientific illustrations and machinery.
6. Studies from cattle—all sorts (no studies from man or woman allowed, unless in becoming habiliments !).
7. Made-up groups and manufactured pictures.
8. New methods of printing, or different manipulations for silver prints from those in ordinary use.
9. Novel applications improvised during the year.
10. Copies of prints or pictures, or sculpture (altogether, for I see no more difficulty in copying a good print than a bad one).
11. Instruments.

It might then yet be a novelty and rest to the mind, since there would be less confusion.—I am, yours, &c.

Wolverhampton. O. G. REJLANDER.

PASTE-BOARD CAMERA BACKS.

To the Editor.

Sir,—From the report, contained in your last number, of Mr. Rogerson's observations on the subject of paste-board camera backs, at the last meeting of the Chorlton Photographic Association, your readers are at liberty to infer, that the Macclesfield Photographic Society has been the means of bringing forward the article to which he alluded. Permit me to say, that although this form of back was introduced, probably for the first time, at the meeting of the Macclesfield Society in June last, and has since met with considerable favour amongst its members, the credit of the idea is due to Mr. W. B. Osborn, treasurer of the Birmingham Photographic Society, who will, doubtless, be able to give any information your readers may desire respecting it. I trouble you with these remarks, in consequence of inquiries having been made from us as to the slide, as well as from a sense of what is due to the gentleman just named.—I am, yours, &c.

C. R. JESPER,
Treasurer to the Macclesfield Photographic Society.

Macclesfield, February 9, 1859.

VALLANTIN'S LENSES.

To the Editor.

Sir,—In answer to a query of your correspondent, "Dublinensis," in your last number, regarding M. Vallantin's lenses, I notice you say that you have never heard of them.

As agent in Scotland for M. Vallantin, will you allow me to inform you, that he has been a manufacturing optician for thirty-five years, and that he has received two medals for his lenses—one (of the first class) at the Paris Exhibition in 1855; and all my experience goes to prove, that his lenses are uniformly very good.—I am, yours, &c.

Glasgow, February 4, 1859. JOHN SPENCER.

WANTED—A SOCIETY.

To the Editor.

Sir,—I wish you would give the Glasgow photographers and amateurs a hint that they are not up to the times—that they, like those in other large cities, should have an extensive Photographic Society and occasionally an Exhibition. I am aware that there is a Photographic Society in Glasgow; but it is a very quiet one. I know, also, that there is the Photographic Society of Scotland; but its head-quarters are at Edinburgh, and few photographers can afford to lose a day, and spend about ten shillings, to see the Annual Exhibition. Hoping that my suggestion will meet with approval, I am, yours, &c. J. R. A.

Glasgow, Feb. 8, 1859.

ANSWERS TO CORRESPONDENTS.

K. R.—Thank you for the news.

James Burns—Have an adjustable front to your camera by all means. We have a scheme for a cheap swinging-back that we may very likely publish shortly—also one for a very steady folding tripod.

T. S. S.—We have never tried lenses by the maker you name—but *report* does not speak very favourably thereof. We think you must be somewhat confused in your ideas about Petzval's new form, which is *not a portrait* combination, as your remarks about the diaphragms seem to imply you imagine it to be.

A Young Beginner—Ammonio-ferric-oxalate is better known as the *ammonio-oxalate of iron;* it is a double salt of a crystalline nature, and of a light yellow colour. It is analogous in composition to the *ammonio-citrate of iron*, which is kept by most druggists, and which latter for photographic purposes may be generally substituted for the former. *Ammonio-oxalate of iron* can be obtained from most good operative chemists, *not druggists*, or may be made as follows:—Into a solution of oxalic acid, pour some per-chloride of iron (kept by druggists), when a yellow precipitate will be formed; pour off the fluid and dissolve the yellow powder in liquor-ammoniæ; evaporate and crystallise.

"R. T. W."—"A hater of Personalities"—"W. Housley"—"Veritas"—"D. W Hill"—"Doubtful," &c., in our next.

THE PHOTOGRAPHIC JOURNAL.

No. 89, Vol. VI.—MARCH 1, 1859.

It is with no small amount of regret that we feel called upon to repudiate the responsibility for anything that appears in these columns; but as regards the last report of the meeting of the Photographic Society of Scotland, given at page 47, we are constrained to do so most emphatically, a portion of it having been couched in language that we cannot at all approve, and would most certainly have declined to sanction for publication under any conceivable circumstances, had the same been submitted to us as usual. Fortunately we were in Edinburgh on the day of publication, and going into the shop of our agent in that city the same evening, we discovered the inadvertence, and lost no time in *immediately* calling upon the gentlemen whose proceedings are commented upon so unceremoniously, in order to express our regret for the occurrence, and to explain how it had taken place. Although the gentlemen alluded to were good enough to accept our explanation as satisfactory to them, we feel that our readers also are entitled to know how the matter occurred, as we should be very sorry to allow it to be supposed that any one with whom we have relations should be liable to similar contumelious treatment, the recurrence of which we have taken stringent measures to prevent in future.

The facts are as follow:—In consequence of what we must still regard as the ill-advised exclusion of our reporter from the meeting of the Society, a member who was present and who dissented from the policy pursued, furnished us with a statement of the proceedings, with comments thereon in the light in which they were regarded by him, but intending the facts only to form the basis for our report.

It unfortunately happened that at the time when the communication came into the hands of our printer (a few hours only before going to press), *we* were wandering in the "Land o'Cakes," and our movements were unavoidably somewhat eccentric, so that no proof for correction reached our hands. Knowing that reports of meetings are valueless unless published within a moderate time after the meetings are held, our printer, with more zeal than discretion, inserted it just as he had set it up and without any editorial supervision at all—hence the somewhat startling form in which it appeared.

There are few matters that have not their comic side, and this is no exception:—so to show how differently the same thing strikes the various parties concerned, we may instance that the culprit in the offence above noticed coolly remarks, that he sees no objection to describing the expressions used by an advocate as "lawyer's slang," *and thinks it not half so bad as calling his assistant a* Printer's Devil. This ought to be conclusive.

In our report of the last meeting of the Manchester Photographic Society, some observations will be found from Mr. Dorrington, relative to the advantage of employing a thin film of albumen or gelatine upon glasses previously to coating the same with collodion.

It is somewhat singular, that on the very day on which we received our copy of that report, being then at Glasgow, we were informed by a local professional photographer, that he had for nearly a year and a half been in the habit of coating all his plates with albumen, whether intended for positives or negatives, upon collodion; and this was without our having previously named to him the communication to the meeting at Manchester. On the following evening, we again met with similar information from an amateur photographer. So that, although in each case a considerable difference in the manipulatory details was recommended, the *principle* was identical; and the concurrent testimony to its value occurring in three different directions appears to us as highly satisfactory.

The Manchester report speaks for itself. Of our two Glasgow friends, the first named, Mr. McNab, described his method of operating as follows:—The glasses being cleaned, some albumen from a new-laid egg having been first mixed with about five or six times its volume of water, is to be lightly rubbed all over one side of the glass by means of a small piece of thoroughly clean sponge, then a quantity of the dilute albumen poured on and off again (the previous sponging being to cause the albumen to flow readily when poured on); and having been drained pretty closely, assisting off the superfluous quantity at the lower angle with blotting paper, the glasses are to be immediately dried in front of a brisk fire, which operation is accomplished in a few minutes' time. The plates can be stored away in racked boxes, and are then ready for the collodion. The film is so thin and brilliant, that it is difficult to ascertain which side has been coated; it is therefore advisable to place them in the boxes with the coated side always turned in one particular direction.

Mr. Church, our other friend, proceeds in a different manner as regards the preliminary operations; and he states, that some dilute albumen with which he coats the plates has been in use for *many months.* To a quantity of white of egg, say one ounce, half a drachm of liquor ammoniæ and six ounces of water are added, and the whole shaken together. The glasses are cleaned with a little dilute nitric acid (acid one part, water three parts), rinsed under a tap, slightly drained, and immediately, while still wet, coated with the dilute albumen, and then dried as above described. By this plan, in course of time, the albumen becomes a trifle more diluted; this, however, causes no inconvenience, and the strength is easily restored by the occasional addition of a small quantity of undiluted albumen.

In the exhibition of the Photographic Society of Scotland, now open at George Street, Edinburgh, we noticed some pictures by Mr. Kibble, of a character very much out of the common way, some being portraits and others landscapes, but all taken with a single combination lens of long focus, and all in a very short space of time, upon dry plates; the exposure varying from the one-fortieth part of a second of time to five seconds for some of the views, in which the ripple on the water, the clouds, the houses, and trees, are all included; the portraits ranging from five to fifteen seconds of exposure. These productions are not without some faults, the landscapes being scarcely as sharply focussed as we should like, for instance, but are highly interesting and valuable, as indicative of accomplishing a great desideratum—the introduction of living objects into our landscape subjects, and that, too, upon dry plates.

We had the pleasure of an interview with Mr. Kibble, but are not at liberty to state more at present, than that his success in this direction is chiefly owing to long-continued and careful developement of the impressed film, well protected from light of

any kind. Mr. Kibble is still actively engaged in the prosecution of his experiments, and as soon as they are completed he has promised to publish the results.

Mr. Kibble's productions are unlike most instantaneous pictures in one very important particular, being of large dimensions; and some idea of the labour undertaken by him may be conceived when we mention that he has coated plates five feet in length, and in one instance has occupied *ninety hours* in the developement of a single picture, the solutions requiring frequent renewal.

We think that the last few months have been prolific in the publication of important points in connection with the dry processes.

We have so many inquiries just now in connection with the toning of paper positives, partly in consequence of a remark we made lately, "that we had considered the use of the *old* hyposulphite bath for that purpose quite exploded," that we presume a few remarks upon the subject may prove acceptable to some of our readers.

Our reason for the supposition expressed arose from the fact that we feel convinced the majority of our professional photographers are desirous of producing proofs that are *permanent* in their character; and as it has been demonstrated beyond a question that proofs toned with gold instead of with sulphur are undeniably more stable, and the manipulation thereof moreover by no means more difficult, we presumed that none knowing the better course would resort to the worse. It appears, however, from the letters we receive, that there are some who are not familiar with the more approved methods of toning with gold.

This material was first employed for the purpose in an acid condition by M. Le Gray; the chief inconvenience experienced being the necessity for an enormous amount of over-printing in order to preserve the proofs from total destruction of the half tones. Mr. Sutton recommended the substitution of sel d'or, or double hyposulphite of gold and sodium, and this avoided the great destruction of the half tints; but, as was demonstrated by Mr. Hardwich, the reduction of the gold was due to the formation of sulphide of silver, and thus the lights sometimes suffered and became of an unpleasant yellowish hue. In order to obviate this yellowness we employed a bath of carbonate of soda between that of the sel d'or and hyposulphite of soda. Subsequently our friend Mr. Forrest, of Liverpool, gave a formula for the use of chloride of gold with an excess of carbonate of soda in one bath, to be applied to the proofs with a brush. In the *Journal of the Photographic Society*, for 22nd of November, 1858, page 88, we find the Editor quoting a bath, suggested by Mr. Waterhouse, in which the addition of citric acid to the preceding is recommended.

On the 7th December last, Mr. Hardwich read a paper, at the Photographic Society, *On Toning with an alkaline chloride of Gold*, an abstract of which appeared in our No. 85, p. 4. We may remark that a typical error (subsequently corrected) there quotes the strength of the gold solution at one grain to the *ounce* of water, instead of to the drachm. The principal novelty introduced is the elevation of the temperature until commencement of reduction of the gold is indicated by a bluish tinge in the solution, in which condition it is exceedingly active. After toning, the proofs are fixed in an alkaline solution of hyposulphite of soda, in order to prevent the chance of liberating sulphur. This is a process that cannot be too strongly recommended as efficient, permanent, and certain in its results; neither is it more troublesome than other methods, especially if performed, as employed by Mr. Church, as follows, viz.:— Take of solution of chloride of gold (eight grains to the ounce of water) one fluid drachm, sesqui-carbonate of soda (commonly called bi-carbonate) one drachm, citric acid twenty grains, water six ounces, and dissolve. Then add to the preceding six ounces of boiling water, and use it immediately. After all redness, when viewed by transmitted light, has disappeared, rinse the prints in common water, and fix in a bath of hyposulphite of soda six ounces, carbonate of soda half an ounce, water one pint — wash as usual after about ten minutes immersion.

We believe that by this process gold is substituted entirely for silver in the formation of the image.

Another very excellent method has been published by Mr. F. Maxwell Lyte, which is very analogous to the preceding, and also produces beautiful results. Ten grains of neutralised chloride of gold, with three drachms of pure phosphate of soda, are to be dissolved in one pint of distilled water. The mixture should be neutral to blue litmus paper; if not, a little soda must be added. In this, as in Mr. Hardwich's method, all free nitrate of silver must be washed away, and the proofs immersed in a weak solution of salt and water before submitting them to the toning bath. Bi-borate of soda (borax) 108 grains, may be substituted for the three drachms of phosphate above indicated. Any quantity of this bath may be prepared and kept in stock, as it does not deteriorate; but only so much of it as is requisite should be employed for toning any prints, and the residue *not* returned to the stock bottle, but any remaining gold, &c., precipitated by any convenient method. The toned prints may be fixed in the bath previously recommended, or in one having a little chalk diffused throughout it — the latter preferred by Mr. Lyte. Either of the above processes is applicable to albumenised as well as to plain paper proofs, and we are convinced that photographers will find much advantage in their use.

We have been favoured by an inspection of specimens of Mr. Hooper's turpentine waxed-paper pictures, which are clear, sharp, intense, and full of half-tone; the process will be found in another column.

Mr. Forrest has also sent for our examination some of the cardboard dark slides alluded to in his note, published in the present number; they are very ingenious, and, in our opinion, so convenient, that we purpose adopting them, with some trifling modification, for dry collodionised plates.

We are informed by M. Martin Laulerie, Acting Secretary of the French Photographic Society, that an extension of twelve days for sending in specimens for exhibition at the forthcoming Exposition at the Palais de l'Industrie will be accorded in favour of foreign contributors, who give notice of their intention to exhibit on or before the 20th instant. Communications to be addressed to M. Laulerie, No. 11, Rue Drouet, à Paris.

OBSERVATIONS ON THE DRY COLLODION PROCESS.

By Charles Heisch, F.C.S.

I am not about to bring forward another new process, and possibly not to say any thing new; but I think one of the objects of societies like our own is, that each member should give the others the benefit of any observations he may make.

During the past seasons I have been working at dry processes; and, like most others, spoiled many plates before I got any good results, and it is the hope of preventing other beginners from spoiling so many, which has induced me, in the absence of any more important paper, to make a few observations this evening. Until last season I had never tried any of the dry processes, because I had not seen any pictures from dry plates which were not hard black or white things, as compared with those from wet plates;* but at the beginning of last summer, Mr. Heath showed me some pictures taken by the Rev. Mr. Cleaver, which equalled any thing I had seen from wet collodion negatives. Mr. Heath kindly procured for me particulars of the process employed by Mr. Cleaver, which I found to be Maxwell Lyte's metagelatine process, with the addition of a little honey and citric acid to the gelatine solution; but the collodion contains a large proportion of bromide, and in this I believe the beauty of his results depends. In No. 76 of the *Journal of the Photographic Society*, Mr. C. has published his process, which differs in one or two points from that he originally sent to Mr. Heath.

* I do not under the head of dry processes include the honey, as that is rather used as a means of preventing the plate from drying.

You are all aware that I advocate the use of two equivalents of iodide to one equivalent of bromide of ammonium, for landscape collodion, wet or dry. I believe the condition of things to be just about this:—that you may take six views on a wet collodion with only iodide, and by a proper arrangement of stops, &c., five out of the six will be very good, but the sixth will not, though by the use of a proper proportion of bromide it may be taken well and easily; while on a dry collodion, if it contain only iodide, for one view that you can take you will find five that you cannot—that is, if you look for any thing like delicacy of half-tone and proper effect. I now always employ the same collodion for dry plates which I before described to this Society, using nothing but iodide and bromide of ammonium.

Some difference of opinion exists as to the kind of collodion best suited for dry plates—some advocating a pyroxyline made at a high temperature, others as expressly directing a low temperature to be employed. My own experience is in favour of a pyroxyline, made at as high a temperature as possible, without producing an explosion, and using plenty of it in the collodion. It is but little use giving formulæ for making pyroxyline, as many very good ones are already published; but it is impossible to communicate the one great requisite—experience; and every one must make up his mind to produce a good deal of bad pyroxyline before he makes any uniformly good. I make my collodion as follows:—

Pyroxyline	8 grains.
Ether	5 drachms.
* Alcohol	1 ditto.

Iodising solution:—

Iodide of ammonium	18 grains.
Bromide ditto	6 do.
Alcohol	1 ounce.

Two drachms of this solution to six of the collodion. This makes a very strong and highly iodised collodion, and requires a bath of proportionate strength; for, in collodion, as in paper, if the bath be weak in proportion to the collodion, the iodide is not firm in the film. This is the case to even a greater extent when bromides are employed than with a simply iodised collodion. The bath I find to work the best is made thus:—dissolve one ounce of nitrate of silver in three of distilled water; to two ounces of this add about three grains of iodide and one grain of bromide of ammonium, previously dissolved in a little water, making the whole up to nine ounces by the addition of water and half-an-ounce of spirit of wine; filtering, and finally adding the remaining ounce of solution of nitrate of silver. It will be observed, that the iodide and bromide are added to the bath in the same relative proportion as to the collodion. I have tried using them in different proportions, but never then got the bath to work so satisfactorily. It is just possible that this may be accidental, but so it is.

The salts of potassium may be substituted for those of ammonium in the bath, preserving the same relative equivalent proportions. I have been led to enter into these details concerning bromised collodion, because some of my friends have been troubled with streaky plates, &c., when endeavouring to use it; and as I believe it to be the proper thing for dry plates, they are not altogether out of place here.

With respect to the various substances that have been proposed for coating the plates, I do not know that, as far as the results are concerned, any one is very superior to the others. The great points seem to be to use it as thin as possible, so as to form a coating at all, and to put it on the plate in a proper manner. I prefer the use of metagelatine, because of its convenience. It will keep any time when well prepared, which renders it superior to albumen, which must be used pretty fresh, and it may be employed cold, which makes it much more convenient than gelatine.

What I have used was according to Lyte's formula, only with the addition of more spirit. It consists of one ounce of gelatine, eighteen of water, and two of spirit of wine. This ensures the keeping of the solution, and makes it run very limpid. The addition of citric acid I am inclined to think no improvement; it appears to have a tendency to produce that excessive intensity which is the great evil of dry plates. With respect to the addition of a little honey, I can hardly yet make up my mind; but I think it may give increased sensibility.

For washing I have used the vertical bath, as recommended by Mr. Cleaver, and believe that it is better not to wash the plates too much: a quart of water will wash a dozen stereoscopic plates quite well.

* The alcohol is distilled first from chloride of calcium, and then from potash, and the ether from potash, so that both are anhydrous, and free from all products of oxidation. They should be preserved in small bottles, quite full.

Much has been said on the necessity of drying the plates in an oven before coating them with the collodion, to prevent blistering. I have no doubt it is a good plan for those who have convenience for it; but if the collodion be kept for some little time after iodising, and the metagelatine be thin enough, I have not found it necessary. I have found the collodion work well after keeping a fortnight or so.

The coating the plate with the metagelatine is the most important part of the process, and it is the proper management of this that enables one to dispense with so much washing. When I first began I did as is usually directed—drained the plate after washing, poured on the preservative solution, and worked it backwards and forwards on the plate for some time before draining it off—and nine-tenths of my plates turned out bad. The preservative solution has, of course, a much higher specific gravity than the film of water on the plate, and when thus mixed with it, makes those whirling sort of marks which always accompany the mixing of solutions of different degrees of density; and even if the movement of the plate be continued till all these whirls cease to be visible, the sensitive coat is often marked indelibly; moreover, whatever nitrate of silver may remain in the film of water on the plate, is thus mixed with the preservative solution, which renders it necessary that the washing of the plate should be very perfect before the said solution is applied. By proceeding in the following manner I have never had a marked plate:—

After the plate is removed from the water bath, let it drain well with its lower edge on some blotting paper, and dry the back of the plate also with blotting paper. When well drained, hold it quite horizontal (a pneumatic plate-holder is the best thing for this purpose), and pour some of the metagelatine all along one of the shorter edges of the plate (about two drachms does for a stereoscopic plate); then tilt the plate very slightly, so as to make the solution flow in one slow even wave to the other end of the plate—not slanting across it. The solution being more dense than the water on the plate, forces the latter before it, and leaves only what is actually in the pores of the collodion; it is quite curious to see the quantity of water thus pumped out, as it were, from a plate which seemed perfectly drained. When the solution has all collected at the lower edge of the plate, tilt it very slightly towards one corner, and allow the excess to flow off; then pour on a second quantity of the metagelatine in precisely the same way, and at the same end of the plate as the first, and let it flow off in the same manner. This second quantity does over again for the first coating of another plate. The plate should then be placed up on end to dry, when it is ready for use. The only other point on which I have anything to remark is the developing, and much depends on doing this sufficiently slow. First make a developer as follows:—

Pyrogallic acid	6 grains.
Spirit of wine	½ ounce.
Glacial acetic acid	½ drachm.
Water	5½ ounces.

After the plate has been well wetted with distilled water, pour over it a solution, made by mixing half an ounce of the above, with half an ounce of water, and two drops of a thirty-grains solution of nitrate of silver. This developes the picture very slowly, and of a feeble light brown colour, but the developement may be continued till all the details are brought out in the deepest shadows. When this is the case, wash the plate and cover it with the undiluted developer, with four drops of silver solution to the ounce; with this any degree of intensity may be obtained, but a rather feeble looking negative prints best, as the peculiar colour of these dry negatives arrests the chemical rays very perfectly—much more so than would be supposed from their appearance. If you begin developing with a stronger solution, or one containing more silver, the high lights develope so much more rapidly than the rest of the picture, that they become quite opaque before the detail is half out. The plates are, of course, washed and fixed in the usual way.

TURPENTINE WAXED PAPER PROCESS.

By W. Hooper.

The paper should be thoroughly dried before it is immersed in the following solution:—

I.

Turpentine or camphene	20 ounces.
White wax	1 ounce.
Iodine	2 drachms.

Dissolve by the aid of heat, placing the bottle containing the above

mixture in a vessel of water kept warm. When the wax is completely dissolved, filter through bibulous paper.

The paper may be left in this solution from five minutes to as many hours, without any difference being perceptible in the result. When it appears thoroughly saturated, it may be taken out and hung up to dry. Make a second solution as follows:—

II.

Water	20	ounces.
Iodide of potassium	300	grains.
Bromide of potassium	50	"
Chloride of sodium	30	"
Sugar of milk	200	"
Iodine......Sufficient to tinge the mixture of a deep sherry colour.		

Or this formula may be varied as follows:—

III.

Serum of milk	20	ounces.
Iodide of potassium	300	grains.
Bromide of potassium	50	"
Chloride of sodium	30	"
Iodine	qu. suf.	

Immerse in either of the above as many sheets of the paper, prepared according to the first formula, as the solution will cover, and allow them to remain about an hour. Let them drain, dry between blotting paper, and then hang them up to dry.

The sensitising solution is composed of—

IV.

Water	10	ounces.
Nitrate of silver	300	grains.
Acetic acid	5	drops.
Citric acid	5	grains.

and the mixture saturated with iodide of silver.

Float the papers on this solution in the usual manner; then wash them in water, in the proportion of *three ounces of water* to each quarter sheet of paper, and preserve the washing water for subsequent use. Make a saturated solution of gallic acid, and take

V.

Gallic acid solution	2	ounces.
Water	1	ounce.
Washing water	1	"

This forms the developing solution.

Any convenient quantity of papers may be placed at one time in this solution, which must be in the proportion of three ounces of solution to every sheet 11 × 9, adding fresh solution in that proportion when every new sheet is immersed in it. Fix in hyposulphite of soda of the usual strength.

As compared with the ordinary collodion process, the time required in the camera is, of course, much greater, say five to ten minutes, with a lens of sixteen inches focus and half-inch stop; but it is much quicker than the ordinary waxed-paper process. The rapidity of the turpentine waxed-paper process depends mainly on the washing.

The only objection to this process lies in the smell of turpentine, which to many persons is particularly disagreeable; but this inconvenience may be partially avoided by the use of camphene.

Printing with this paper may be done by gas-light; in about five minutes the details come out, if the light is sufficiently strong.

In washing the sensitised papers the water employed for the first lot, in proportion as above given, may be *added* to an equal quantity of fresh water for the second lot of papers, thus gaining the convenience of a larger quantity to manipulate with; while the *strength* of the dilute nitrate of silver, thus washed off the papers, *remains the same*—an important feature in obtaining uniform results. A third and any subsequent number of additions to the first quantity of water may be added in a similar manner; hence one of the objects of preserving the washing waters.

Too great a proportion of bromide reduces the intensity of the skies.

I have never kept my papers more than two days, so cannot speak as to their quality in this respect; but by immersing any not used in the solutions II. or III., they are restored to a condition ready to sensitise on a future occasion, and I fancy they then give even better results.

HINTS ON THE FOTHERGILL PROCESS.

By John Glover.

I have for some time worked this process with great satisfaction, and have just developed a negative on a plate prepared about eighteen weeks ago, giving proof of not the least deterioration from keeping. I am, therefore, constrained to add my quota of experience in favour of this beautiful and certain process; the more so, as I conceive I have simplified the means of preparation and fathomed to the very bottom the causes of failure. I shall therefore enumerate the main points to be most carefully and undeviatingly attended to, and the reason for each.

First, on removing the plate from the bath, *allow it to well drain, and lie on the levelling stand half a minute before pouring on the washing water.* This will allow the æther to evaporate, and the film will be in a condition *not to repel the water*, the pouring on of which is the most delicate part of the operation, and unless done as above, the negative will be liable to patches more or less sensitive than others.

Secondly, *drain off the washing water most thoroughly at one end of the plate,* using blotting paper to absorb the last portion; then pour on the albumen *at the contrary end to the one at which the plate was drained,* slightly inclining, so as to flow steadily across. When it reaches the opposite end, *allow one-half to run gently over into the waste dish;* this carries away the last portion of the weak silver solution, which, if allowed to mix with the albumen in quantity, would coagulate and *be carried back over the other portions of the plate,* tenaciously adhering to the film, and preventing the subsequent action of the developer: semi-transparent, wavy markings, are the result.

And now comes the washing away of the albumen, which must be completely done.

The simplest and quickest mode is as follows:—have ready a large vessel of common water, and a good sized bottle of distilled water; into each, drop a quarter-inch india-rubber syphon, weighted so as to be held near the bottom. Near the opposite ends of the syphons place clips to stop the running at will, and insert glass tubes, three inches long, and five-sixteenths of an inch in diameter, into the extreme ends through which the water makes its exit; these being larger than the bore of the body of the syphons diminish the velocity of the stream. To wash away the albumen, lay the plate across the mouth of any earthenware jar, the whole standing in an empty wash basin, the roundness of the bottom of which allows the plate to be inclined in any position. Elevate the bottoms of the water-containers to the level of the plate to be washed, the syphons being sufficiently long to reach every part. Commence washing with the common water, the plate being slightly inclined, beginning at the uppermost edge. Bring the glass tubes as near the film as is consistent with safety, liberating the water with a movement from side to side, gradually advancing towards the lowermost edge; this takes about ten seconds for a stereoscopic plate. Stop the water and lift up the plate to drain for a moment, and repeat the washing, this time elevating the end last washed; again drain a moment, incline the plate at a considerable angle, and flush with distilled water from the other syphon, then rear up on blotting paper to dry spontaneously.

Contrary to the theory already propounded, I find that whether this last washing be continued for a long or short period the sensitiveness is not affected, nor do I perceive any difference between the plates washed in the dish as directed by Mr. Keene or as above, only that the latter is most certain to remove the surplus albumen and is sooner and easier accomplished. It is obvious that washing with a stream in the first instance, on removal from the bath, would interfere with the sensitiveness; but from my experiments I find that the compound of silver and albumen is not easily disturbed, unless undue mechanical action is allowed to take place in the washing. This is a fact well worth knowing and I hope will prove useful to many who are now perplexed as to the amount of labour to expend upon the plates.

The print I enclose is from the plate eighteen weeks old, exposed on the 28th of January, two minutes, Ross's four-and-a-half-inch focus lens, usual stop. I was anxious to know what it would turn out, and like most other photographers, in a frenzy, I am sorry to add, and sometimes photographers in earnest too, rushed at the first subject that presented, the point of sight chosen being the balcony of the back kitchen. King Fog was holding one of his levees; a yellow January sunlight was peeping over the houses behind, leaving the foreground in shadow and scantily lighting up the principal object, viz., an unbroken line of broken railings geometrically parallel to the horizon. The distant tenements were merging on obscurity, all but enshrouded in the garments of his majesty aforesaid, and if it were possible to look beyond the veil, your editorial eye would revel in the mysteries of the Mersey and the great ships on her bosom; so that my picture, as the knowing artist would say, "leaves a deal to the imagination," and his brother exhibition critic might exclaim at the same time, "altogether presenting a charming composition."

[Notwithstanding the drawback of a subject chosen as described, the result is decidedly favourable to the *modus operandi.*—Ed.]

HINTS ON THE FORMATION OF PHOTOGRAPHIC SOCIETIES.

Scarcely a place on the map of Great Britain but what can boast of its photographer, amateur or professional; and where one true disciple of the art exists, others by the force of his persuasion or example may become such. In all small towns the elements of a photographic society, association, or union, may be said to be lying dormant, and only require the quickening spirit of an enthusiast to bring them together. To such an one the task is simple and easy. Let him first give a popular lecture on the subject, explaining the principles of the art, in as simple and as non-technical language as possible, adding a brief sketch of its history, and illustrating the subject with as many varied specimens as he can make, beg, or borrow for the occasion. Lecture over, let him contrive something of a *conversazioné*, or get up a little discussion, so as to "bring out" the latent photographers, and when the proper degree of interest is excited, then will be the time to propose the formation of a "Society."

The Society formed — How shall it work? We must beware of making it too formal or too cumbrous in its working machinery. At first its business may be limited to weekly or other periodical social meeting, at which each member may contribute his quota to the evening's entertainment, either by carrying photographs for exhibition, by raising some useful point of discussion, or by undertaking to explain certain features in the art with which he may be best acquainted, or in which an unusual degree of interest may be excited. It is very probable that the brunt of the labour may at first rest upon the shoulders of the enthusiastic promoter of the society; but if he possess tact and patience, he may soon shift a portion of his burden to other shoulders. If several societies were to form a "Union," and exchange periodically their photographs, the interest and usefulness of the individual societies would be greatly increased. It is important for the success of such infant societies, that the promoter be a well-informed practical photographer, and he will be the fit person to appoint Secretary. As there may in many cases be a difficulty in the way of forming a governing body of President, Vice-President, Treasurer, &c., these may be advantageously dispensed with — a good working Secretary is worth them all, as they too often prove only "pompous nobodies." The subscriptions from the members may be regulated according to circumstances, from five shillings to a guinea per annum; and if it can be contrived that they shall get something for their money in the way of a photograph so much the better. The expense of rent may in most cases be avoided: for if the Society consists at first only of a few choice spirits, let them meet at each other's houses, and discuss actinism over their tea and toast. It must not be forgotten that photography includes many clever ladies amongst its votaries, and their aid and countenance must on no account be overlooked.

The error committed in forming many Photographic Societies that now exist, or have existed, consists in modelling them on the pattern of regular scientific societies, in which it is expected that original papers shall be read on the evenings of meeting. Now photography is not a subject that admits of that mode of treatment: its real discoveries, such as prove of general interest, are few and far between each other; the little modifications and variations of processes are of interest only to the photographer, who is "deep in for it" in the black art. A much more useful course of proceeding would be, for the Secretary to make up a summary of the progress of photography, which he might collect from the various photographic and scientific journals, and so keep the members *au courant* with the advances made in the art. This would afford an opportunity for interesting discussion, and serve to keep an interest that might otherwise flag. These photographic journals should be subscribed for by the Society, and after they are examined and used by the Secretary for the purpose indicated, might circulate among the members.

In large towns, the business of societies of this kind might assume wider proportions; still, it would be better, in the first instance, to engraft them on some existing literary or scientific asciation, and when they have gained sufficient strength to "go alone," to do so. The social and æsthetical elements, rather than the scientific, are those most likely to conduce to success; all may however be judiciously combined, but the feature most necessary to success and progress is that which secures a distribution of photographs amongst its members, after the fashion of many book societies.

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

At an ordinary monthly meeting, held at Myddelton Hall, Islington, on the 23rd ultimo, George Shadbolt, Esq., Vice-President, in the Chair, after the minutes of the previous meeting had been read and confirmed, notice was given that the following alterations and additions to the rules would be submitted for confirmation at the Annual Meeting, in March:—

1. In Rule 6, there be inserted—"That at the ordinary meeting, in February, the officers for the ensuing year be nominated, any member being at liberty to propose names."
2. In Rule 4 — "That instead of one, two Vice-Presidents shall be elected."
3. "That the payment of Five Guineas in one sum shall constitute a Life Member."

Officers for the ensuing year were then nominated for election at the next meeting.

Mr. Hannaford practically demonstrated his iron printing process, and a vote of thanks was accorded to him.

A discussion then ensued.

Mr. Hislop doubted if iron prints *were* permament, as he had a few days ago seen some written papers where the ink had decidedly faded and turned yellow.

Mr. Hannaford was of opinion that this might have been owing to the presence of sulphur, which need not occur by the iron process.

Messrs. C. J. Hughes. J. Spencer, G. Shadbolt, and other members, took part in the discussion on printing and toning generally which ensued.

Mr. Shadbolt exhibited some paper transparent positives and negatives, taken by the turpentine waxed-paper process, by Mr. Hooper, of Manchester, giving very excellent results.

Mr. Shadbolt also exhibited some card-board single and double backs, designed by Mr. Forrest, of Liverpool, and improved by Mr. Hooper, of Manchester.

Mr. C. J. Hughes called the attention of members to vulcanite as a substance preferable to wood or paper for the like purpose, and would wish to know if it had been or could be introduced into use.

Mr. W. Hislop, F.R.A.S., exhibited and explained the use and working of a portable stereoscopic apparatus, made by Mr. Rayne, having a dark box containing a dozen plates, to which the back of of the camera was fitted, and by means of a slide and spring the plates could be transferred from the box to the back, and, after exposure, from the back to the box again, each plate being transferred in rotation. The weight, including the iron top of the stand, plates, and case, being only seven and a quarter pounds, and the price about £3 10s.

Mr. Hill exhibited a beautiful glass transparency, produced by Fothergill's process, by Mr. E. Heseltine.

Mr. Legg presented a card of admirably executed photographs of microscopic objects for the portfolio of the Association.

At the next meeting, on the 30th instant, Mr. W. Hislop has promised to exhibit his lantern for photographic diagrams and pictures.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

A meeting of the above Society was held at the Golf Club House, on January 17th, 1859; the President, J. Glaisher, Esq., F.R.S., in the chair.

After the usual business had been disposed of, a paper was read by Charles Heisch, Esq., F.C.S., on *Observations on the Dry Collodion Process.* [See page 54.]

CHORLTON PHOTOGRAPHIC ASSOCIATION.

[In our last we omitted full particulars of the following report, from motives of delicacy, in consequence of the complimentary nature of some of the remarks; but, finding from a communication that our forbearance has been regarded as a slight upon our kind supporters (an offence of which we certainly had no intention of being guilty), we have no option but to insert the whole, as furnished to us.—Ed.]

The usual monthly meeting of the above Association was held at the Chorlton Town Hall, on the 9th February, 1859, the Vice-President, Mr. J. A. Deane, in the chair.

Mr. Hooper exhibited to the meeting the syphon that he employed for rapidly changing the water when washing prints

thereby thoroughly removing the hyposulphite of soda from them in a short time.

Mr. Wardley stated, that a print washed quickly by a continual changing of the water is more likely to be a good one than when the washing is continued for a long space of time; but that different samples of hyposulphite of soda have different effects on the print, even when toned by the same process.

Mr. Deane highly approved of the method of washing recommended in *The Photographic Journal*, and had, some time ago, taken his prints out of the water to drain and again washed them, as he considered they required, say about six hours in all, and none had yet faded.

Mr. Rogerson was precluded by indisposition from attending to read a paper he had prepared for the meeting.

Mr. Whaite called the attention of the members to what he considered the very unfair treatment which Mr. Greenwood, the proprietor of the late *Liverpool and Manchester Photographic Journal*, had experienced at the hands of the London Photographic Society. He briefly stated the facts of the case, and added, that he thought it a question which concerned photographers generally, and one on which the Society might properly express its opinion. He therefore begged to move —

"That this Association highly approves of the change in the size and title of the now called *Photographic Journal*, and sympathises with its Proprietor in the uncalled-for interference to which he has been subjected on account of changing the name of the Journal to one more worthy of its character."

Mr. Hooper said that photographers were much indebted to Mr. Greenwood for the enterprise and ability displayed in his Journal, and he thought they should lend him their moral support when he had been unjustly interfered with.

Mr. Nicholson hoped some modification might be made in the motion before it was put to the meeting. It embodied two distinct propositions: first — an approval of the change made in the size and title of the Journal; second — an expression of sympathy with Mr. Greenwood under the treatment he had met with. To the latter he made no demur whatever, considering that Mr. Greenwood, in the exercise of his undoubted right to select any unappropriated name for his Journal that he might think proper, had been somewhat hardly dealt with; but he thought it would be imprudent of the Society to commit itself to any expression of opinion on the title which Mr. Greenwood had selected. One was a question of a public nature, which they might very properly deal with; the other was one proper enough for the exercise of individual opinion, but which a public body had nothing whatever to do with.

Mr. Fawcett did not see the force of Mr. Nicholson's objection. He thought they could not properly express their sympathy with Mr. Greenwood, unless they were convinced that he had acted rightly in the change which he had made.

Several members spoke to the excellence of the Journal, and thought the Proprietor was quite justified in adopting his present title.

Mr. Nicholson said that he had no desire to withhold his testimony to the value of the Journal; he believed it was not inferior to any of the photographic serials in point of usefulness or respectability. *He did not even call in question the propriety of the change in title;* it might be good or it might be bad; it was simply a matter for Mr. Greenwood to exercise his own judgment upon, and he thought that the Society, instead of expressing its approval of the particular title which Mr. Greenwood had selected, would exhibit greater wisdom and better taste by limiting its expression of opinion to a *disapproval* of the course pursued by the London Photographic Society. As he could not support the motion, he should submit the following amendment:—

"That this meeting, without expressing any opinion as to the appropriateness of the change made in the title of the *Liverpool and Manchester Photographic Journal*, desires to express its warm sympathy with Mr. Greenwood in what it conceives to be an unwarrantable interference on the part of the London Photographic Society."

Mr. Heywood thought the question of the title a very unimportant matter. What they had to consider was—Had Mr. Greenwood reason to complain of the way in which he had been treated? The members seemed to be agreed on this point, and as the amendment expressed that opinion without entering upon matter which in no way affected the case, he should second it.

The Chairman thought the amendment expressed a very lukewarm sympathy indeed with Mr. Greenwood. For his part, he felt that a great wrong had been put upon him, and if legal proceedings were commenced against him as threatened, he, for one would willingly subscribe his guinea to a defence fund.

Mr. Wardley expressed the same sentiments, and said the Journal was not surpassed by any for valuable information.

After some further discussion,

The Chairman remarked that it would be very desirable that the expression of opinion which emanated from the meeting should be unanimous, and as there was no difference amongst the members as to the unjust proceedings of the London Society, he hoped Mr. Nicholson would withdraw his amendment.

Mr. Nicholson was sorry to put himself in opposition to the Chairman and many members whom he greatly respected; but he looked upon the point at issue between them to be a very important one. He said it was very remarkable that not one of the speakers to whom he was opposed had addressed themselves to the question which he had raised, but had confined their remarks to a point on which his opinion did not differ from theirs; he therefore felt that he had no objection to answer. As his amendment contained nothing to which an objection had been offered, and the original motion did, he should feel it to be his duty to press the matter to a division.

The amendment was accordingly put, and subsequently the original motion, when the latter was declared to be carried.

A vote of thanks to the Chairman was carried by acclamation, which concluded the business of the meeting.

LIVERPOOL LITERARY AND PHILOSOPHICAL SOCIETY.

At the usual fortnightly meeting of this Society, held at the Royal Institution, Colquitt Street, on Monday last, the 21st ultimo, Mr. William Keith read the following paper:—

Photography: Past, Present, and Prospective.

In treating upon the subject of "Photography: past, present, and prospective," he said he proposed to consider, first, the early discoveries in this science, which had paved the way to its present state; secondly, its present position; and thirdly, the probable future application, and the assistance we might reasonably expect from its more extensive application. We did not now regard the productions of the camera with that curiosity and astonishment which were bestowed upon its earlier efforts, on account of the daily and intimate acquaintance which we now had with its results. The most indifferent of its productions were not, however, without their value in the diffusion of knowledge, and an increased appreciation of the beauties of nature and art. We might reasonably infer that the old alchymists, in their search after the philosopher's stone, became acquainted with the fact that some of the preparations of silver were darkened by the action of light. The earliest date, however, which we found was 1777, when the illustrious Scheele made the first philosophical examination of the decomposing action of light upon compounds containing silver, and pointed out what we might consider one of the fundamental principles of photography, without which all our knowledge would be capable of producing very little practical result, namely, the fact that chloride of silver was most sensibly acted upon by the blue ray, while the red and yellow rays produced comparatively little result. His experiments were repeated in 1801 by Ritter, of Jena, who discovered the existence of powerful actinic ray beyond the visible spectrum; and about 1802, Wedgewood and Sir H. Davy attempted the first practical application of photography, and published "a description of a method of copying paintings upon glass, and making profiles by the action of light upon nitrate of silver;" but although these and similar experiments appeared at the outset to promise so well, they were checked by the experimentalists being unable to discover any means of fixing the pictures so obtained. In 1814, M. Nièpce, of Chalons, discovered that certain resins were acted upon by light, in such a manner that they became hardened and insoluble. He coated a metal plate with a solution of bitumen, and exposed it to the action of the light; the parts acted upon became insoluble, and the parts representing the shadows were then dissolved out. Ten years afterwards he entered into a partnership with Daguerre, who, in 1839, published the details of the daguerreotype process upon silver plates, which, however, was not perfected until the subsequent discovery, by Goddard, of the accelerating action of bromine.

The fixing processes employed up to this time were very imperfect, and the matter was not set at rest until the publication of a paper by Sir John Herschel, on the use of liquid hyposulphites for fixing the photographic impressions. In 1840, Mr. Fox Talbot published a paper in the *Philosophical Magazine*, in which he gave directions for the production of both negative and positive pictures upon paper prepared with chloride of silver, and in February, 1841, he took out his patent for the calotype or talbotype process. To Sir John Herschel we were indebted for the first employment of glass plates to receive sensitive films, although he (Mr. Keith) believed it might, with equal justice, be attributed to Mr. Towson, of this town. In the present advanced state of the science of photography, it might be urged that all these processes are obsolete, but in them they might trace the germs of all the processes

at present practised. Without the knowledge of the different actions of the various coloured rays, we could not avail ourselves of the processes which required developement in a chemically dark room. The chloride of silver, the first substance experimented upon, was still used for nearly all the printing processes; and in the later discoveries of Daguerre and Talbot, we had the processes which depend upon the property which certain substances possessed of receiving a latent image, to be subsequently developed. In the bitumen process of Nièpce, and the chromotype of Ponton, we had the basis of carbon printing, and also the known processes of photoglyphy and photolithography. Having described the various kinds of apparatus employed by photographers, Mr. Keith proceeded to say, that the discovery in 1851, of the application of collodion to photography, might, he thought, be considered to commence the present era. The daguerreotype could not be applied with advantage to small portraits.

The talbotype was not sufficiently sensitive, and was, in addition, wanting in delicacy and fine detail, while the collodion was found in practice to combine the excellencies of all previous methods, and to possess besides some peculiarly its own. It had more rapidity of action than even Daguerre's process. It was applicable to pictures of a much larger size, and capable of almost unlimited reproduction; and it surpassed Mr. Talbot's, not only in sensitiveness, but also in superior descrimination of texture and minuteness of detail. There had been considerable difference of opinion as to whether Archer or Le Gray was entitled to the merit of the discovery. Le Gray certainly proposed its use in 1849 or 1850; but to Mr. Archer we were indebted for the first details of the practical mode of using it. The improvements since that time had been very rapid, and its extensive application might be inferred from the fact, that in a recent exhibition, out of 700 subjects, 600 were due to collodion. By its aid we were enabled to look upon the face, as it were, of all that was great, good, and noble, in this and other lands; the stupendous monuments of antiquity were brought to our own firesides. It really almost did away with the necessity of travelling. India, China, Egypt, Palestine, France, Germany, Italy, and Switzerland, had been ransacked, and we were no longer left in doubt as to the accuracy of the artist's pencil, for we knew that photography could not lie.

In considering the various uses to which photography could be applied, Mr. Keith gave some interesting instances of its practical value. During the building of the bridge of Kieff, photographs were taken every week for the information of the late Emperor Nicholas; in the Ordnance Survey Department of the Sappers and Miners, all the maps are reduced by photography, thus effecting a saving of about £2000 per annum; and it was also extensively used in the Royal Military Repository at Woolwich. In fact, there is scarcely a business or science to which photography might not render valuable aid. To the naturalist and botanist, how valuable must the faithful transcripts of nature be? To the astronomer it offers a ready method of mapping the starry firmament. Photographs of the moon had been taken, which showed very clearly the mountains and valleys which marked her surface; Jupiter, with his belts and satellites, had also been taken, and a series of very interesting experiments, to ascertain the comparative illuminating power of the various planets, had been instituted by, he believed, Mr. Warren de la Rue, and there was no doubt that our knowledge of the wonders of the celestial world would be materially increased by its use.

The transfer of the photographic picture upon stone or metal, for the purpose of ready and cheap multiplication, had occupied the minds of some of the greatest men of the day. M. Fizeau attempted to etch daguerreotypes with a mixture of nitric, nitrous, and hydrochloric acid. The white portions resisted the action of the acids, and the black portions were bitten in. It was then inked, and the surface covered with a thin film of gold, deposited by the galvanic battery. The ink was then dissolved with a caustic alkali, and the plate again bitten in either with acids or by being made the positive pole in a battery arrangement. Mr. Talbot patented, in 1856, a process for engraving on steel, in which he used a mixture of gelatine and bichromate of potash, subsequently improved and further patented in 1858. By his new process the plate was prepared as in his former specification. After exposure to light, an aquatint ground was laid upon it, and it was then bitten in with a solution of perchloride of iron. The photogalvanographic process of Herr Pretsch was capable of producing very beautiful results, although, from the number of repetitions, the cost was considerable. He also used the bichromate of potash and gelatine, but spread upon a glass plate. After exposure the plate was wetted, when the parts unacted upon swelled up sufficiently to admit of a mould being taken in gutta percha. This was placed in the battery as a mould, and copper deposited upon it, which served as a matrix from which the working plate was obtained. In a specimen recently issued by Mr. Greenwood, the process was still further lengthened out, by printing from the copper plate upon transfer paper, and printing from the stone. Photolithography had also its votaries. Mr. Macphearson, of Rome, coated the stone with a solution of bitumen in ether. Exposed to the light under a negative, the bitumen was rendered insoluble, and a wash of ether removed the unchanged portion. The latest and most promising process was that of Messrs. Cutting and Bradford, patented in the United States and England, which consists in preparing the stone with a mixture of gum-arabic, sugar, and bichromate of potash. It was then "lighted," and washed with a solution of soap, which attacked the stone, removing the coating, and fixing itself, or an insoluble soap formed by the mutual decomposition of the soap and the stone upon the stone, in place of the coating removed. Where the gummed surface had been entirely protected from the light, the gum was easily removed, and the soap had free access to the stone. The consequence was a thorough union of the soap with the surface. Where, on the contrary, the lights were strong, the gum having been rendered much more insoluble, was protected from the action of the soap, and at all intermediate points the effect of the soap upon the stone was inversely proportionate to the extent to which the gum had been affected by the light.

The uncertainty attending the old methods of silver printing had set many experimenters upon the process of carbon printing. Of these, two were before the public — that of Messrs. Salmon and Garnier, who prepared their paper with a strong solution of citrate of iron, exposed, and then applied the carbon, by means of a pledget of cotton wool; and that of Mr. Pouncy, in which finely-prepared carbon was mixed with gum-water and bichromate of potash. After exposure the unaltered carbon was washed out, but neither of these processes have yet produced pictures equal to the silver process. M. Sella and Mr. Perry had also brought out a process of printing, in which the picture was formed of the ordinary colouring matter of writing ink, gallate of iron. It had been improved upon by Mr. Hannaford, who had made public a proces of ink printing which promised well. He mixed albumen with bichromate of potash and ammonio-citrate of iron, with which he coated his paper. It was then exposed to the light, and after exposure washed in water to remove the unchanged bichromate. It was then immersed in a weak solution of ammonia, and afterwards in a weak solution of chloride of gold. It was then developed with gallic acid. Mr. Burnett had furnished us with a number of highly suggestive experiments in printing with the salts of cobalt, copper, uranium, and other metals, which would no doubt before long bring forth their fruit. As regarded the future of photography, he had not much to say. Its application to calico printing, and to all the arts and sciences, were numerous, and likely to become more so every day.

Professor Archer, though not a practical photographer, had been much surprised that manganese had never been used as a photographic agent. The effect produced by light on glass containing manganese was very powerful, rendering it a deep purple. In consequence of this, every particle of glass had had to be removed from the roof of the Chester railway station. Where the glass had been covered by putty it was found still unchanged.

Mr. Keith said, experiments were being made relative to this part of the subject, and so far they had been attended with very satisfactory results. In his new room he had employed glass coloured with cobalt, which had been found quite unchangeable under the influence of light.

Professor Elliot drew attention to some curious facts illustrative of natural photographic processes. In taking a picture to pieces which had been exposed to a strong light, he had found a perfect photographic impression of the subject imprinted on the panel underneath. Trout, it had been observed, on being transferred from one stream to another, accommodated themselves to the different colour of the water in the course of four or five hours. He had read some interesting remarks on this subject by the gamekeeper to the Duke of Buccleugh.

Mr. Foard remarked that it had been mentioned in *Notes and Queries*, and instances given in which trout had taken a photographic image of leaves, &c., with which they had been in contact while lying on the bank.

The Chairman thought this might be explained by the fact that the colour of the whole body of the fish had changed in dying with the exception of the parts which had been in contact with the leaves.

Professor Elliot said, still it was the action of light; but in the living trout the effect was more striking. In Scotland, on one side of a lake red trout would be caught, and on the other side black, and people supposed they were different species; but the difference was no doubt owing to the colour of the stones at the bottom.

Mr. Bell observed that there was such a thing as bottling-up light. Water absorbed a large portion of light, and it was very possible that being thus retained it might act powerfully upon the trout, and produce the changes that had been described.

Dr. Collingwood, in allusion to the specimens of chromo-photography which were said to have been produced, expressed his opinion that the future of photography was the taking of pictures in natural colours. The author of "Two Years Ago" had spoken very strongly on the subject.

Mr. Keith did not feel very sanguine as to this part of the future of photography. If the products of metals which in burning gave fourth coloured flames, such as strontian, sulphur, &c., were deposited by the galvanic battery on metallic plates, those plates might give the power of reproducing the same colours.

Mr. Bell had worked for many years with the daguerreotype, and had frequently had the plates with all the natural colours upon them; but with the slightest action of light, or a little increased vapour of mercury, they were all gone.

Mr. Foard considered it altogether an accidental circumstance. All such statements must be received with considerable doubt. It was easy for those who were not very correct in their observations to make mistakes of this kind. Persons had come to him, and told him they had succeeded in producing a blue sky, which was nothing more than a defect in the picture, occasioned by decomposition under the action of light. Others believed that they had produced green foliage; but these effects

were not at all to be attributed to the pictures being transferred in their natural colours.

Professor ARCHER spoke of the effect produced by placing in the dark two highly polished silver plates, one engraved and the other not. The result would be, that the engraving would be transferred to the unengraved plate, which, by being exposed to the fumes of iodine or bromine, would exhibit a picture having all the character of a photograph. This experiment had been produced by our own countryman, Möser, to show the effect of latent light.

The CHAIRMAN asked what was supposed to be on the surface of the unengraved plate to produce the effect?

Mr. BELL would call it a film of light.

Professor ELLIOT, speaking of photographs of the moon, said, it had struck him as possible that another curious result might be attained by the employment of photography in connection with astronomy. There might be stars giving out only actinic rays, and, consequently, not visible by our present means of observation; but by presenting to them different coloured plates, they might be discovered.

In reply to an observation by the Chairman,

Mr. KEITH said, many substances besides cotton had been used for the purpose of producing collodion, but none appeared to answer so well. It was an interesting fact that Mr. Hardwich, in the last edition of his "photography," stated that cotton was the material first tried, and after experimenting upon many other substances, he had come back to cotton.

Professor ARCHER said, the experiments had proceeded in a wrong direction. Instead of going from a finer to a coarser substance, the object should have been to go from the coarser to the finer. There was silk-cotton and various other products, which were too fine to spin, because they had not that ridge on the edge of the fibre which cotton had, and consequently they would untwist again; but they would probably answer admirably for collodion. They were very cheap, and easily obtained; they were almost all finer than cotton, and transparent, which cotton was not. Consequently, they were well worth experimenting upon.

Mr. BELL said, what was wanted was something that the ether would take up without leaving a residuum.

The thanks of the Society were voted to Mr Keith.

Exhibition.

MACCLESFIELD PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Exhibition of Photographic productions which was noticed in our number for January 1st, as being about to be held in connection with the Macclesfield Society, has since taken place. We then observed, that the Society thought well not to occupy a thoroughly independent position, but to join another institution; and although this course involved some inconveniences, as for instance a considerable curtailment of the time allowed for viewing the pictures, yet under the peculiar circumstances of the case, it appears to have been the best, and indeed the only one that could have been pursued.

The opening took place on Monday, the 17th of January, and although it had been intended, in the first instance, to continue the Exhibition for two or three weeks, it was found necessary to bring it to a close on the evening of the 21st ult. A good deal of local interest appears to have been aroused, and by the assistance of the catalogue of the photographic department, we are enabled to place the more noteworthy features of the collection before our readers.

It was hardly to be expected that a new Society, entirely free from patronage, and only depending on the energy of workers and that liberal spirit which characterises the followers of our art, should have been able to collect into its first Exhibition much that should be new to the photographic world; even though its aim was not so much to test the progress and photographic status of its own members, as to give them and their townsmen an opportunity of judging, by comparison, of different processes, and of the present capabilities of the art when skilfully employed. Accordingly, we are not surprised to meet again with the often-shown but not on that account less beautiful sea and cloud pieces by Le Gray, Nos. 136, 146, &c., whose *Fortifications of Brest* (155), and two pictures of *Brest Harbour, with French and Russian Fleets* (182 and 184), are also not less excellent.

The Society of Arts contributed about thirty pictures, upon a varied range of subjects, many of which afforded ample materials for study.

Mr. Fenton's series of *Views from Welsh Scenery* was well represented; though we are informed that it was found impossible to show all that were contributed, some strikingly beautiful ones being brought forward for the first time for the inspection of the Society at its February meeting. Of those exhibited, perhaps *Pont-y-Pant* (185), and *Miner's Bridge over the Llugwy* (158), may be named as the most striking.

Of photographs of paintings, engravings, &c., we may note a number from pictures in the late Art Treasures Exhibtion at Manchester, contributed by Mrs. Legh, Lyme Hall, being Nos. 93, 98, 118, 120—3, 125, 129, 132, 133, 152; a large frame of beatifully copied engravings (22), by Mr. A. Brothers, Manchester; also a copy, *The Three Apostles* (56), by Mr. F. M. Mercer.

Another series of *Welsh Views* were contributed by Messrs. Mudd, Manchester, of which Nos. 41, *Pont-y-Lledr*, and 38, *A Mill near Trefriw*, elicited general commendation; the former from the beautiful rendering of the gradations of distance, the latter from its artistic effect. No. 41, *Pont-y-Pant*, however, contributed by the same gentleman, was less effective than Mr. Fenton's picture taken from the same point. We may also make honourable mention of Mr. Osborne's *Views of the Interior of Aston Hall, near Birmingham*; of *Carnarvon Castle*, from a negative by Mr. W. Jackson (84); and especially of the *Views of Whitby Abbey* (Nos. 134 and 139), from negatives, by Mr. W. Pumphrey, York.

Of views of local interest, chiefly contributed by the Society's own members, the best were—*Old Moreton Hall, near Congleton* (106), the negative by Dr. Hill Norris's dry process; and *Chorley Hall, Cheshire* (45,) by Messrs. Mudd; as well as several very beautiful scenes from the neighbourhood of the Earl of Shrewsbury's seat at Alton, contributed by the Rev. W. F. Ribbans, of Leek, and printed by developement from waxed-paper negatives. The pictures of *The Fountains* (92 and 102), speak well for the capabilities of this process.

There were also good specimens in stereoscopic views and copies from statuary, but none calling for notice from us. In portraiture we observe a copy, enlarged with good effect, by Mr. John Eastham, of Manchester, from one taken in India, of Captain Stanley. Many other specimens were also not without merit.

If there be such a thing as antiquity in photography, we fancy it is approached by No. 1 of the collection, a talbotype print of *The Seine at Paris*, contributed by Mr. Wilson, of Preston; and ample means were afforded for appreciating the progress which the photographic art has made since these were the order of the day, by inspection of the photoglyphs by Fox Talbot, 74 and 75, the photogalvanographs, 165, &c., and the new carbon prints by Mr. Pouncy, Nos. 85, 89, &c., one of the latter of which, an *Abbey View*, was minutely criticised in one of our recent numbers.

We cannot but regret that the Exhibition was so speedily closed; but doubtless the Macclesfield Society will have learned much by this their first lesson that may be of use to them in future years: all that we have to do, therefore, is to encourage them to make progress, really and not pretentiously, in the path which they are already treading.

Letters to a Young Photographer.

No. V.

MY DEAR EUSEBIUS,

Who shall decide when doctors differ? Photography has as many knotty points as medicine, and the ways of unravelling them both are devious and uncertain. In my communications to you I carefully avoid speculative suggestions, and endeavour to limit myself to the fruits of my own experience. You say you find much discrepancy in toning and fixing processes: we have to modify our practice by experience. Experience has clearly shown to me that the toning bath made according to Mr. Hardwich's original formula, is unsafe if used after the gold is eliminated from it by more proofs than it can colour. When this condition arrives, the proofs are toned by sulphur instead of gold: hence their instability. It is a mere matter of calculation how many proofs of a given size a given quantity of chloride of gold will tone. Every picture 9 × 7 consumes about one grain of chloride of gold in the process of toning, and yet, when one such picture is burned in a crucible, the residue yields only 0·12 grain of chloride of gold, showing a loss of 88 parts out of every 100 employed. This fact shows the necessity for looking after the residues of baths, washings, &c. Now, the quantity of so expensive a commodity as chloride of gold required for toning, induces amateurs to pursue a false economy; and they frequently continue to use a bath long after all the gold is abstracted, being satisfied with their proofs becoming coloured, no matter how. Herein lies the danger and uncertainty of the compound toning and fixing bath. If it be allowed to stand exposed to the atmosphere a few days undisturbed, the gold may be observed floating on the surface in a bright metallic film, showing complete decomposition; and still such a bath will tone as well as ever. The de-

teriorating influence of this decomposed bath upon proofs toned in it, is thought to be due to the presence of free acid, which liberates the sulphur from the hypo, and toning the proofs by converting the chloride of silver into the sulphide of that metal. Now, to show you that sulphur-toned prints are not entitled to sweeping condemnation, I may as well tell you at once that I have toned and fixed many hundreds of proofs by sulphur alone, without the use of chloride of gold at all. I proceed in the following manner:—

I first wash my proofs to remove the free nitrate of silver, and then immerse them for about half an hour in a bath of hyposulphite of soda, of the strength of sixteen ounces of hypo to five pints of water. Upon removal from this bath the proofs are carefully rinsed, and then placed, for a few seconds, only in the following:—

Water	40 ounces.
Hyposulphite of soda	9 drachms.
Sulphuric acid	36 minims.

Stir the mixture with a glass rod; it soon becomes milky and disengages the odour of burning sulphur. The washed proofs are immersed in it, one at a time, and very carefully watched. The red hue quickly disappears, and violet, purple, and black tones supersede each other in rapid succession; but as the tones are much deeper when the proofs are dried, they must be removed before they acquire that depth of tone it is desired they should ultimately possess. When taken out of this bath, the proofs must be immediately immersed in clean water and well rinsed. The only precautions to be taken in adopting this method of toning are, to strictly limit the quantity of sulphuric acid to the proportion of hypo indicated; and not to allow the proofs to remain an instant longer in the bath than is necessary to impart the desired colour. The bath soon loses its property of toning, and proofs immersed in it after it has been prepared for an hour, become yellow and grey in the lights and shadows. This method is as sound in theory as it is good in practice; but I shall not afflict you with philosophical explanations at present. You may take my word for it, that proofs toned in this manner are just as brilliant and permanent as those toned by any other process in general use, and are moreover quite undistinguishable from those toned in the ordinary gold bath. I have no idle fears in the employment of acids in the process of toning, the point to hit is to apply it at the right time.

When we employ separate baths for fixing and toning there is but little risk that the proofs will be toned by sulphur instead of gold. You may easily discover when the bath is exhausted of its gold. In the bath composed according to M. Bayard's formula, decomposition sets up in a few days if the solution is left exposed to the air, the gold floats in a thin pellicle on the surface; but I obviate this inconvenience, by keeping the bath when not in use in a bottle filled up to the stopper the atmosphere being excluded, the liquid is preserved unchanged. I do not think it necessary to lay much stress upon the advantages of an alkaline bath; it is certainly safer than an acid one; the danger appears to consist in the liberation of free acid in the presence of so unstable a compound as hyposulphite of soda. And yet this would appear to be contradicted by what takes place in the method by acid hypo indicated above, when sulphur is set free and does the work of toning. The danger may be in the protracted time of immersion; for this method requires but a few seconds contact with the free acid and sulphur. I have found its quick action very advantageous when there has been many proofs to tone at one time; and although there may be a great consumption of hypo, there is a corresponding saving in time

Photographic Glossary.

Dry Collodion Process — A modification of the ordinary collodion process, in which the sensitive film is exposed in the camera in the dry state. It is sometimes confounded with *preservative processes*, from which it differs somewhat, as the object of some of the *preservers* is to keep the collodion in a moist condition.

Dynactinometer — An instrument invented by M. Claudet for measuring the intensity of the actinic power, and for comparing the relative quickness of lenses.

Efflorescence — Certain salts, such as sulphate of soda, when exposed to a dry atmosphere, part with their water of crystallisation, and fall into a state of powder, or effloresce. Others absorb moisture from the atmosphere, and become liquid; these are said to *deliquesce*.

Elliotype — An application of the property possessed by chloride of silver of darkening by exposure to light. It cannot be called a photographic process, as it acts without the use of the camera. A painting is made in transparent and opaque body colours upon a piece of plate glass, which is then placed in the ordinary printing frame, and pictures are obtained which may be produced in outline or in *chiaroscuro*, and are fac-similes of the drawing. This invention is guarded by a patent!

Engraving — Heliographic engraving consists in the preparation of a sensitive surface on a steel, copper, or zinc plate, or on lithographic stone, which, when acted upon by light, allows an etching or inking effect to take place, so as to admit of impressions on paper being taken from the plate or stone, as when they are engraved in the ordinary manner. Various processes have been invented by Mr. Talbot, M. Poitevin, Herr Pretsch, Mr. Newton, and others, for full details of which see various articles in the pages of this *Journal*.

Energiatype — A photographic process possessing very great sensibility, invented by Mr. Robert Hunt, which is better known under the name he has substituted for it — *Ferrotype*.

Ethers — Ethers are named after the acids by whose action on alcohol they are produced. When ether is prescribed in photography, sulphuric ether is indicated. There are nitric, acetic, hydrochloric, oxalic, and other ethers. Sulphuric ether is a very volatile, fragrant, colourless, combustible fluid. Its vapour is exceedingly heavy; it may be poured from one vessel into another like water; it forms a very dangerous explosive mixture when mingled with atmospheric air and ignited, and should be handled with extreme caution in the presence of an open light. Ether is extensively used in photography as a solvent of gun-cotton in the preparation of collodion. The specific gravity of pure ether at 60° is 0·724. The chemical expression for ether is oxide of ethyl. It is of the same composition as alcohol, minus one equivalent of water.

Equivalents — Chemical equivalents are those relative quantities in which bodies combine to form new compounds. All substances combine with each other in definite proportions, or in multiples of a given number, thus the proportion in which oxygen unites with other elementary bodies is 8, or its multiples, 16, 24, 32, &c. The equivalent of sulphur is 16. When this quantity of sulphur is combined with two equivalents of oxygen, 16, there is produced one equivalent of sulphurous acid (32). When the same quantity of sulphur is combined with three equivalents of oxygen (24), one of sulphuric acid is produced (40), therefore the numbers 32 and 40 respectively, are the equivalents of sulphurous and sulphuric acids. These equivalent numbers may represent any given quantities, such as grains, ounces, or pounds, so that the proportions continue the same. The law of combining proportions is as important to the chemist as the loadstone is to the mariner.

Foreign & Colonial Correspondence.

Paris, February 22, 1859.

THE time for receiving photographs intended for our next Exhibition is fast approaching, and will extend only from the 1st to the 15th of March. I hope, therefore, that your readers will bestir themselves, and not allow their pictures to arrive here too late, as happened to many on a previous occasion. The Exhibition will continue open from the 1st of April until the 15th of June, and rumour is already very busy in announcing what gems of art and evidences of industry we may expect to behold. There would be some advantage resulting to the Committee of the Exhibition if artists would at once notify them of the pictures they intend to send, without waiting until they are actually despatched. A concession has just been made in favour of foreign exhibitors, whose productions will be received twelve days later than those of native artists— that is, up to the 27th of March — provided notice be given prior to the 20th proximo. The names of the jury include many of the most distinguished professors and amateurs of photography; and, as it may interest you to know them, I will enumerate them here:— There is the Count Aguado, M. Bayard, Bertsch, Cousin, Delessert, Davanne, Foucault, Hulot, Jean-Renaud, Lemaitre, Count Leon Laborde, Le Gray, Moreau, Peligot, and Robert, besides the officers of the French Photographic Society. I must explain, that all the names enumerated are not photographers, but some are artists, and

others are scientific professors. There is a good mixture of varied talent, that must go far to secure a competent and impartial jury.

At the last meeting of our Society some proofs were exhibited, sent by M. Asser, of Amsterdam; but as he does not communicate his method of producing them, I can only notify you of the fact of their appearance. M. Brebisson explained his method of carbon printing, which includes some points worthy of notice. He prefers to make use of a highly glazed paper, floated on a mixture of bichromate of potass and gelatine. This paper, although kept in the dark, will not preserve its sensibility longer than two or three days. The gelatine appears to lose its solubility, and the proofs taken on it lack vigour. The exposure in the pressure-frame he states to be required is one-fourth more than given to paper sensitised with chloride of silver. The proof is removed as soon as the deepest shadows come out of a light red colour. We must not wait for the appearance of the half-tones and minor details. Taken into a dark room, the proof is fastened at the corners by gum to a glass plate, and then the powder is dusted over it with a piece of cotton wool. He employs blacklead, lamp black, or red chalk, all in a state of impalpable powder; but he prefers a black pigment prepared by M. Delahaye, which I suspect to be the fine carbon produced by the combustion of coal gas. When the black is spread evenly over the surface of the proof by means of a slight friction, the sheet is placed blackened side uppermost in a dish, and a stream of boiling water poured over it, gently agitating the dish. The water dissolves the greater part of the bichromate of potass. A fresh quantity of water is then poured over the proof, so as to clear the picture: this operation must be performed with a soft brush, or a pencil may be made with a piece of fine muslin rag. The layer of gelatine unacted upon by the light is easily removed; but this operation is very delicate, and must be guided by the nature of the design, so as not to remove the delicate parts by too much friction. If the exposure has been too prolonged, the adherence of the carbon is diminished, and the deep shadows will have a disagreeable red tint. On the other hand, if the exposure has been insufficient, the gelatine comes off in large flakes, and the picture loses its chiaroscuro. A cloudy but light sky is is more favourable to exposure than strong sunlight. It will be remarked of this method that the carbon is applied to the gelatine after exposure to light. A complicated machine for cleaning glass plates, invented by M. Richardin, was exhibited. It will admit of as many as five hundred plates being cleaned with it in one day; but, from its dimensions and complexity, it must be regarded in the light of a curiosity.

I have seen a stereoscope constructed with a double frame at the part where the picture is placed, for the admission of pieces of coloured glass, which impart a tone of colour to the transparent slides. Our photographic world is very much astonished to find the reasearches of M. Nièpce so coldly received in England, being, in fact, almost ignored. They console themselves by thinking, that as the sun seldom shines upon London, no opportunity has occurred for repeating the experiment of storing up light. M. Nièpce lately invited Mr. Wheatstone to his laboratory to witness the experiment of producing a photograph by the agency of light stored up in a tin canister. Mr. Wheatstone accepted the invitation, when M. Nièpce took a piece of card, previously impregnated with tartaric acid and rolled up since last June, in a tube hermetically closed. In company with Mr. Wheatstone, M. Nièpce proceeded to a dark room: he then took a piece of paper sensitised with nitrate of silver, upon which he placed another to serve as a positive, merely a piece of paper inscribed with large characters; he then opened the tube held vertically, with the open end downwards, then placing this orifice upon the positive which covered the sensitised paper, and left the tube in this position for about ten minutes, then removed it. The paper became blackened in a circle in the parts corresponding with the opening of the tube, and the letters of the positive were distinctly traced in white on a black ground. Mr. Wheatstone will take some specimens with him to London, and exhibit them there. J. P.

Geelong, Australia, Dec. 14*th*. 1858.

I HAVE been making some experiments with an old plan of Fox Talbot's, which he used for paper, and which is, I believe, in his first specification, but I have never heard of its being applied to collodion; it is to produce a positive instead of a negative by the first operation in the camera.

I took a positive collodion and prepared the glass plate in the usual way, and after immersion in the bath, well washed it and exposed it for half-a-minute to the direct light* of the sun (if now developed it would blacken all over). I then take a solution of iodide of potassium, thirty grains to the ounce of water, and let it flow over the plate several times, returning it to the bottle, expose in the camera, and give it rather longer than usual that the light and hydriodate may *bleach* the part previously acted on by the light.

* It may be exposed first and washed after.

I now return to the dark room and well wash the plate under the tap, immerse in the bath and drain, then pour on the positive iron developer, when the picture comes out as a transmitted positive (negative superficially), and from it any number of negatives can be made.

Sometimes, however, I find the bleaching has not acted enough, and a negative is produced. Here is a wide field open to us to find the quickest bleacher; this will perhaps surpass in celerity the quickest exciter.

I have made several experiments on varnishes for positives. I have used Mr. E. T. Hobson's and Mr. Maddison's, and find Maddison's the best, but his recipe makes it too thick and it cracks; it is better made thus:—

In a two ounce bottle, put

Gum Juniper .... $1\frac{1}{2}$ drachms.
Gum Thus .... 1 drachm.
Fill up with spirits of wine.

It will now be plenty thick enough; it is much whiter and brighter than Mr. Hobson's. The plate must be warmed before it is applied or it chills.

I expect that from five to ten grains of mastic would bind it and prevent it cracking, this being a soft gum and used as a binder by varnish makers; but the above I have tried and it answers. I have found out a varnish that protects the positive picture from air and water, and is *invisible*, slightly improving the blacks by cleaning them, the whites *not* turned grey or altered (the picture can be tinted first), then the skies and draperies coloured (dusted in) in *dense* colour (it is highly adhesive), or painted in oil if required on *it*, and it will have the appearance of an ivory miniature in a remarkable degree (no spots ever occur). It can then if required by the customer be made vitrious by the use of the ordinary white varnish. I have sent the recipe to my wife, Mrs. Sparke, 50, Chapel Street, Devonport, and if any of the trade likes to arrange with her they can bring it out. I have tried long to get it, as the small quantity of free nitrate, or cyanide of silver, after a time absorbs water and produces black spots in our strong light here.

A. K. SPARKE.

Jersey City, New Jersey, United States of America, January 20*th*, 1859.

CAN you, in the plenitude of your wisdom, or from the abundant sources of information you have access to, inform me if any of the *bromides* were used in *collodion* previous to July, 1854? This question is of the gravest importance to all the photographers of the United States of America. You are aware, that a patent was granted to one Cutting, of Boston, for improvements in photography, one improvement being the use of *bromide of potassium* in the collodion. This patent has been tried and sustained in a court of law; not, however, by argument but by default, the defendant choosing rather to pay a penalty than litigate the matter.

Now it does appear monstrous that after the liberal manner in which both English and French philosophers have given their discoveries in this art to the world, a man in the United States of America should be so lost to generosity as to trammel the art by patents for what may fairly be doubted he ever discovered.

I need not ask you to aid our fettered art. I am sure your heart is open to every solicitation, and that you will set the ball in motion to gather as it rolls the information required.

Who was the first to use bromide in collodion? or was it used previous to July, 1854?

W. CAMPBELL.

[The evidence is as clear as daylight that bromides were used *before 2nd June*, 1853, as on the evening of that day papers were read at the Photographic Society (at the Rooms of the Society of Arts, Adelphi, London), one by Sir John Herschel, *On the substitution of Bromine for Iodine in Photographic Processes*; and a second by Mr. Crookes, in which he details the results of experiments he had made with *bromised collodion*, in consequence of the suggestion of Sir J. Herschel. Mr. J. B. Hockin, of Duke Street, Manchester Square, London, is stated to have made the collodion alluded to by Mr. Crookes. These papers were *published* 21st June, 1853, in the *Journal of the Photographic Society*, pages 70 and 71, and in the succeeding number for 21st July, 1853, Mr. Crookes published, page 86, a formula for the bromised collodion which he had employed.—ED.]

Correspondence.

TONING, &c.

To the Editor.

Sir,—I was very much pleased to see in your "Letter to a Young Photographer," a recommendation to use M. Bayard's mode of toning, for strange to say, I picked it out to tone some prints I was about to present to our Society's folio, and in your report you will read the opinion of our members with regard to their *tone* and sharpness; it was what I am fond of—an experiment, and I am glad to find my choice backed by yourself. I am told that it is but a neutral bath, and not *alkaline*, what do you say? Do you think it permanent? It is certainly very quick and simple, and I find that if I fix or finish the prints in a new hypo and gold bath, I obtain even finer results; will this, in your opinion, affect their permanency? How long do you find that you can keep the bath in working order? I find after two days a red prismatic scum covers the surface, and indelibly stains a print where a particle touches it. There is, I think, a large proportion of gold in it, and should tone more than an amateur can do in two days, otherwise it is not an economical toning bath.

I should be glad of your opinion and assistance in your next on this matter, as many of our members, after seeing my pictures, are trying it. Would you also kindly inform me where I may find a description *(practical)* of card-board backs for holding dry plates; for a long journey they would be lighter and cheaper than the wooden ones. Can they be purchased? I am, yours, &c.

Manchester, February 16*th*, 1859. JOHN L. DAVIES.

[The article mentioned is not our own, but from the pen of a co-adjutor, a practical hand at photographic printing. The bath is not *alkaline*, and the red hue first produced on mixing the ingredients is indicative of the presence of free acid, or at least of a compound, acid to test paper. The permanency of the prints we should consider unquestionable if toned in a *new* bath, but problematical in an old one. The scum is an indication of the bath being exhausted. See our leader, also Mr. Forrest's letter in the current number.—Ed.]

CARDBOARD BACKS, &c.

To the Editor.

Sir,—I noticed in your last *Journal* a letter from Mr. Jesper, claiming for Mr. Osborn, of Birmingham, the credit of inventing card-board slides for cameras. If you will refer to THE *Journal* for 1854, you will find I brought forward the same thing five years ago, and that Mr. Atkinson of this town made card-board cameras about the same period.

An improvement has been made in my slide by my friend Mr. Hooper, of Manchester. I send you both plans for inspection, and take this opportunity of sending you several communications I have received from him on the turpentine waxed-paper process, with illustrations. He is so throughly practical in all he does, that I am confident my brother photographers will find his statements to be exactly correct. The portability of waxed-paper is certainly greatly in its favour.—I am, yours, &c.

Liverpool, February 18*th*, 1858. J. A. FORREST.

GOOD TASTE.

To the Editor.

Sir,—I have just now read, in an over-the-sea contemporary of yours, a bitter attack on you, on sundry grounds, but primarily because you have seen fit to modify the title of your periodical. What, however, I especially remark in the article in question, is his daring impertinence in calling your "good taste" and "gentlemanly courtesy" in question, as if he possessed the smallest share of those qualities himself, or had any idea what constituted either the one or the other. Anybody who happened to read the unwarrantable personal attack he made on the editor of a contemporary in his paper, a little more than a month ago, will have formed an opinion of his taste and courteous feeling not likely to be effaced; and it is absolutely disgusting to find such a man presuming to lecture another on the want of qualities of which he himself can have no more conception than a Gorilla.

What makes his attack on the gentleman I have mentioned still worse, is the fact, that he not only published a letter from a man boasting that he had by a falsehood successfully imposed upon the former, but headed it by some observations of his own, proving that his moral perceptions were as blunted as those of his correspondent.

As a specimen of what this individual considers "good taste," I quote a passage from the last number of the periodical under his direction. After enumerating a lot of articles, which he chooses to call novelties, he goes on—"We (I) shall always be happy to back the efforts of any firm in bringing forward a useful novelty, by calling attention to it in this Journal—*provided always that a specimen of the article be forwarded for our inspection.*"

Begging that you will do a constant reader of your Journal the favour to publish this letter, I beg to subscribe myself as

A HATER OF PERSONALITIES.

RE BOTTLE DIAPHRAGMS.

To the Editor.

Sir,—Southey has written in his "Doctor" a motto that I would commend specially to photographers—

"May my candle go out in a stink if I refuse to confess from whom I lighted it."

I have no desire to discourage the *revival* of old inventions *acknowledged as such*, which certainly may be useful, or to render any amateur accountable for all that has been done or invented in the subject he takes up as his hobby, and still less do I expect him to read all that has been written on this particular pursuit; but I would simply suggest a little research.

The above diaphragms, claimed by Mr. Ross, were invented by Martin, of Paris, for obtaining clouds in his panorama camera, one of which I purchased certainly twelve years ago.—I am, yours, &c.

222, *Regent Street.* W. E. KILBURN.

[We are always glad to have an opportunity of rendering credit to the originator of any thing useful, and thank our correspondent for his intimation; but, at the same time, we must express our conviction, that Mr. Ross was equally an inventor of the arrangement. We had never met with it before, and it is, therefore, not at all surprising that it was unknown in the United States of America.—Ed.]

MAGIC LANTERN SLIDES.

To the Editor.

Sir,—Being desirous of obtaining information on the following, of a reliable character, I take the liberty of requesting replies in your valuable Journal—

1st. Wanted, formula for the best negative process for portraiture, including collodion.

2nd. Wanted, formula for the best process for the production of magic lantern slides.

3rd. A friend of mine recommends the introduction of a small piece of nitre into the developing solution for positives *on glass*, for the production of brilliant whites. Do you think it calculated to effect the object? If so, what quantity will answer?

4th. Wanted to know how to prepare paper positives for the reception of oil paint; also, please inform me the diameter of quarter, half, and whole plate lenses, and oblige, yours, &c. R. T. W.

Liverpool, February 10, 1859.

[1. For this we must refer you to Hardwich's *Manual of Photographic Chemistry*, or to Horne and Thornthwaite's, Hennah's, Squire & Co.'s, or Bland & Co.'s shilling pamphlets. It would take far too much space to reply to this query in detail.

2. Any of the dry processes will give this desideratum, or you can copy from a negative in the camera. Remember, however, that in any case the pictures should be slightly *over-exposed* and *under-developed*, to give transparency.

3. Yes. Protosulphate of iron fifteen grains, water one ounce, nitrate of potash (nitre) ten grains.

4. Immerse the proofs in a solution of isinglass, three or four grains to each oz. of water; the solution should be quite warm—hang up to dry.

You do not state whether you mean portrait or landscape lenses; but in either case there is no *definite* size for the diameters; the size of picture depends more, but not solely, upon the focal length of the lens.—Ed.]

PRINTING DIFFICULTIES.

To the Editor.

Ssr,—Allow me as a reader of your *Journal* from the first, to trouble you for aid in some photographic difficulties. As I pursue this art only for pleasure, I have been too ready in following the recipes of various operators, only to spoil my chemicals.

I take much pleasure in the printing of positives, using albumenised paper, say 10 grains chloride of ammonium, and nitrate of silver 60 grain solution, three drops of acetic acid to each ounce of the latter; but of late my views have been rendered doubtful by a communication in your last No., addressed to a Young Photographer, recommending 5 per cent. of the chloride of ammonium, and that no acetic acid be added to the silver solution.

As I understand, 5 per cent. is ten grains of a chloride to a fifty-grain solution of silver, also that the addition of acetic acid to the silver solution tended to keep the whites of the print pure. Your opinion is earnestly wished for on these points:—

1. What is really the best chloride, sodium, barium, or ammonium, for salting albumenised paper?

2. Is 5 per cent. ten grains to fifty-grain silver solution?

3. Is the addition of acetic acid, say three drops to the ounce of the nitrate of silver solution, advisable or not?—I am, yours, &c.

Glasgow, February 9*th*, 1859. DOUBTFUL.

[Chloride of sodium for albumenised paper is that which we prefer, but for the plain paper, chloride of ammonium. 2. Five per cent. of chloride means thirty grains to the ounce of albumen, or albumen and water. If the albumen be *undiluted* we think twenty grains enough, as the film will be thicker. The letters you name are written by a skilled practical photographer. The per centage is not intended to apply to the sensitising solution. 3. The addition of an acid to the silver bath *retards* the action of the light, but otherwise does no harm. If the lights remain pure without it, leave it out; but some kinds of paper imperatively demand it, owing to an impurity in the manufacture.—Ed.]

VALLANTIN'S LENSES. TONING PROOFS.

To the Editor.

Sir,—In the last number of *The Photographic Journal*, a correspondent wished for your opinion of "Vallantin's" Lenses, of which you had not heard. Having tried several, I find them all that can be desired; they quite equal Lerebours, and have the advantage of being much cheaper. Mr. Bolton, of Holborn Bars, is the agent.

I differ from you respecting Hardwich's toning process; the prints should be slightly over-printed, as the toning bath reduces them a little, and if *not* sufficiently toned, they will lose considerably in the hypo, which I think one cause of "Dublinensis'" failure, and the lights not being clear was owing to the paper having become discoloured from keeping before it was toned.—I am, yours, &c.

Islington, February 9th, 1859. D. W. HILL.

COVERING MICROP-HOTOGRAPHS.

To the Editor.

Sir,—You have always shown in your *Journal* such great liberality in making known your methods of micro-manipulation, that I am induced to ask you to favour me in your next number, with the best method of fixing the small glass disc upon the micro-photograph. My plan has been, to dilute the Canada balsam with an equal part of spirit of turpentine, then drop from the point of a pin one drop over the photograph, and bake for some time on a copper-plate over a spirit lamp. The objections to this plan I find to be—

1. If not baked long enough, the disc does not set firm. If too long, it discolours the photograph, and air bubbles appear underneath.

If this is the only method of doing it, how am I to know the exact time to allow, or is there a better mode?

2. What is the best material to employ, in order to clean large plates that have photographs upon them, that have been varnished with the American ambrotype varnish.

3. What do you consider the best developer for very small locket portraits, for giving firmness combined with density?

Trusting you will not consider I am taxing your kindness too much,

I am, yours, &c. VERITAS.

London, February 8th, 1859.

[1. You can procure Canada balsam sufficiently fluid for the purpose of mounting without the addition of turpentine; it should be about the consistence of molasses. It is better without than with the turpentine, though the latter can be used. Proceed thus:—take a spirit-lamp, and cut the wick *very short and conical in form*, which will cause it when lit to produce a short small blue flame, which consumes but little spirit and is very manageable. Hold your glass slide over the flame and in contact with it, so as to flatten out the flame a little, and keep the glass moving in a circular direction so as to warm about a *circular inch* of the glass, otherwise it will probably break: the heat should be about as hot as can be borne by the back of the hand without flinching, *then* drop from a pin a little of the balsam, and allow it to evaporate until nearly solid, warm the *thin* glass over the flame and apply it to the balsam, not flat, but a little slanting; it will generally settle itself at once and drive out any bubbles of air, but if any be enclosed, a little heat cautiously applied by the aid of a spirit-lamp will drive them out.

2. We do not know the varnish you mention, but expect that soaking in solution of soda and water for a few days will soften it. Try also benzole as a solvent.

3. Do you mean for positives or negatives? If the former see answer to *R. T. W.;* if the latter, pyrogallic acid three grains, citric acid one grain, water one ounce, at this time of the year; but in Spring use two grains of the pyrogallic acid instead of three.—Ed.]

COLLODIO-ALBUMEN PROCESS.

To the Editor.

Sir,—As I find I am not up to the mark in the collodio-albumen process, I shall be glad of your valuable assistance—that is, if you think a reply to this will be useful to others as well as myself.

1. In several formulæ for the process, I have seen a large quantity of glacial acetic acid recommended in the baths. I should like to know if this is necessary, and why?

Mr. Robinson, in the *Journal of the Photographic Society* for May, 1857, recommends only one minim to the ounce of bath, and only uses one bath; and he says in the same Journal for July, that his bath is, after six months' use, as colourless as when first made.

2. I scarcely understand Mr. Riley's letter, in your Journal of July 15. Does he float the plate with uniodised albumen? and if so, is it better than if iodised? and are the pictures as good as by the old process, as they seem to be taken in a deal less time?

3. I think if you would give a formula that you know to be good, it would be useful; and, for my own part, I shall be glad of any advice on the subject you please to give. If there is anything in back numbers, please say in which, and I will get them, as I have only been a subscriber since June last.

4. I should like your advice respecting the buying of a half-plate portrait lens; I want one to take landscapes as well. Do you think I may reasonably expect the front lens to take pictures 9×7 good to the edges? Are French lenses worse than English, as I find they are sold for less? I shall be obliged for any information on the subject you please to give.

I am, yours, &c.

Bakewell, Feb. 9, 1858. WILLIAM HOUSLEY.

[1. The acetic acid is intended to prevent discolouration of plates in darkness.—Mr. Robinson is, however, a skilful photographer.

2. Uniodised albumen. Two specimens exhibited to us by Mr. Riley were very good. We have some doubts, however, about the length of time his plates would keep before being exposed.

3. You will find in our volume for 1857 full particulars, at pages 58, by Mr. Sidebotham; 137 and 145, by Mr. Ackland; 209 and 222, by Mr. Draffin.

4. You cannot have a landscape and portrait combination in one, without sacrificing some excellence in one capacity. We could not, with fairness, recommend any particular maker, but may safely say, that as a *rule*, English lenses are better than foreign ones; but this is by no means without exception.—Ed.]

ANSWERS TO CORRESPONDENTS.

Wilhelm — We have carefully examined the photographs, by the late Robert Howlett, to which you allude, taken with the orthographic lens, and certainly must admit that they are as sharp and perfect as can possibly be desired, but we have no means of knowing the size of the aperture employed.

T. B., Leeds — For information about Vallantin's lenses, see letter of John Spencer, in our last, and D. W. Hill, in the present number.—Those of Derogy we have never tried, but we examined one recently at Glasgow, and were informed that it worked satisfactorily. The bayonet joint, instead of a screw, we like; but some sort of *spring* is wanted to prevent a slight amonnt of "shaking" at present existing.

K. B. B. — Chloride of lime is a misnomer, as there is no such chemical compound; the substance known by that name is simply lime, impregnated mechanically with chlorine gas. The compound would be chloride of *calcium*, the metallic base of lime.

One in a Fix — Like many others who use dry plates, you have forgotten to add some nitrate of silver solution to the developer before pouring it on to your plate, and, consequently, there is nothing to form the expected picture — "*ex nihil nihilo fit*." Remember that the picture is formed out of the nitrate of silver alone, by the agency of the insolated iodide, and as dry plates have the nitrate washed away, it must be restored before, or at the time of, developement.

Thos. Markham — See replies to Wilhelm and T. B.

Medicus — 1. To make a bath of sel d'or, take eight grains of terchloride of gold, and dissolve in half an ounce of water; add to it solution of carbonate of soda, stirring well after each addition, until all effervescence ceases, and litmus paper is no longer reddened when immersed therein; make up with water the quantity wanting to measure *one fluid ounce* in all. You will now have a solution of the double salt, known as chloride of gold and sodium, containing one grain of the gold salt in each fluid drachm of liquid. (Should a precipitate be formed, it is in consequence of a slight excess of soda, and the defect may be rectified by the addition of a drop of hydrochloric acid). Next make a solution of hyposulphite of soda twenty-four grains, water one ounce. To prepare your bath proceed as follows:—Add one fluid drachm of the gold solution to two ounces of water, and one drachm of the hyposulphite solution in a *separate vessel* to another two ounces of water; pour the former (the gold), into the latter, stirring all the time; the sel d'or bath will then be ready for immediate use.

2. Quite possible to take stereoscopic pictures with a half-plate square camera, but it would require to have a front piece for the lens specially adapted to *shift its position*, and the dark slide would want a plate frame to take glasses, $6\frac{3}{4} \times 3\frac{1}{4}$.

3. Plenty of half-tone is easily obtained if the exposure be sufficient in the camera; if the collodion be too dense, add about half a grain of bromide of ammonium or cadmium to each ounce.

4. Glacial acetic acid is not *absolutely* necessary for a positive iron developer, but it is better to use that than any of a lower strength for this purpose, as it generally contains fewer impurities.

Stereoscope — You will find Burfield and Rouch's dark box for manipulating in the open air all you can desire. A bi-lens camera by all means; we are not so sure that it is really more expensive than the other arrangement named. You can give any amount of distance when you desire it with a bi-lens camera, as well as with a single lens one, by simply using one lens at a time. See pages 130 and 169 of our last volume.

A. K. Sparke — At page 206 of our last volume, you will find the process given by Sir William J. Newton, for transferring the collodion film to paper.

London — See our leader.

A Constant Reader — Your diaphragm is identical in principle with that of Mr. Sykes Ward, described in our last, but not so simple in construction.

R. B. R., Simon, Emma Knight, T. P., and Lux — You will find replies to your queries in our Leader.

T. C. D., and several other correspondents we are constrained to postpone until our next.

THE PHOTOGRAPHIC JOURNAL.

No. 90, Vol. VI.—MARCH 15, 1859.

During our recent visit to Edinburgh, we had, by the courtesy of Mr. Kinnear, the Secretary of the Photographic Society of Scotland, an opportunity of inspecting the silver medals recently awarded by that Society to the Rev. Mr. Raven and Mr. Lyndon Smith, as prizes for the best photographs exhibited by members and strangers respectively. If we were to state that the awards had given universal or even general satisfaction, we should be making an assertion that would tax rather severely the credulity at least of those who have had any, even the smallest experience in such matters; but in the instance before us, the mode of selection adopted (by general vote of the members) is peculiarly open to the liability of causing dissatisfaction.

We express no opinion upon the merits of the productions selected: the donors are of course the best judges of what they wish to encourage; but if they must give prizes, a proceeding which we by no means recommend, we strongly advise that for the future the votes of the general body of members be taken, for the purpose of determining, not the pictures entitled to obtain the reward, but the individual to whose judgment the selection shall be left; or, if preferred, three arbitrators might be chosen. At the first glance this arrangement may appear to amount nearly to the same thing, but it is not so in fact. It is easier far for the uninitiated in science or art to select a person in whose judgment they can place confidence, than it is for them to exercise discrimination upon points respecting which they themselves are only imperfectly informed. Moreover, competitors are more likely to be satisfied, as they have more certainty regarding the special points upon which they are called on to contest.

In a mixed assembly like any photographic society, many members will be found to give a vote upon the most extraordinary grounds; for instance, one gives it for what he considers the "sharpest" picture, without reference to subject, point of view, or in fact anything else; while another, having a great notion of size in a photograph, because he finds the manipulation of large plates troublesome, accords his vote to the picture covering the most extended surface. A third, having an eye *only* for artistic selection of subject, chooses one good in that respect, but perhaps having every fault possible in a photograph excepting that one avoided; whilst a fourth, having an antiquarian propensity, is so taken with the fidelity of representation as regards some coveted specimen, that he cannot conceive the possibility of anything of a higher character existing. Now, by the plan we propose, these dilemmas and absurdities are avoided, while by voting for the arbitrators each member has a voice in the matter.

An arbitrator or arbitrators being appointed, the selection of the pictures can be made, and at the same time the *reasons given* for the choice decided on. Successful candidates will then know the points in which their special excellence is supposed to consist, and unsuccessful ones will at least have the satisfaction of being made acquainted with the cause of their failure.

It appears to us that this method of proceeding would be far more likely to encourage that which is deemed desirable of attainment in our art, than the rather haphazard one adopted in the present instance.

We trust that these remarks will not be regarded in the light of fault-finding interference; they are addressed to our readers generally, to whom we feel bound to express an opinion upon all matters photographic that we have carefully considered; and as the giving of prizes for photographic skill appears to be a practice coming into vogue, we consider it is our duty to offer such suggestions as we think likely to further the progress of photographic science and art.

There is a matter of serious importance to the interests of photographers generally, but to professionals especially, that calls for speedy attention; we mean the daily increasing propensity amongst a certain class to impose restrictive limitations to the free use of various processes and materials in connection with photographic pursuits. This is an evil of much greater magnitude than appears at the first blush, and one likely to interfere materially with the progress of our art. The Council of the Photographic Society would do well to take into consideration whether any legitimate means might be adopted to obviate the continuance of a practice likely to prove seriously obstructive.

If any person, by patience, perseverance, and industry, succeeds in introducing an improvement, either in a process or piece of apparatus, although it may be brought about in consequence of suggestions unreservedly communicated to the public by others, he may, if he be so minded, secure to himself the exclusive privilege of its enjoyment by means of a patent; and although we may not in such a case approve of his illiberality, we cannot question his *right* to act as he may please with what is undoubtedly his own; but what we do complain of, and what photographers will do well strenuously to resist, is the now too frequent attempt to secure by patent that to which the pseudo-patentee *has no right whatever*. That this evil is a daily increasing one we have abundant evidence before us; and we will, by way of illustration, call attention to a few cases in point.

In our last impression we published a letter from a correspondent in the United States, desiring information relative to the period when bromides were first used in collodion in this country, as a patent had been obtained in America in July, 1854, to secure amongst other matters the exclusive use of this class of material, which supposed right has recently been enforced by legal proceedings. Now we cannot say exactly how long prior to the date mentioned, bromides had been used in collodion in this country; but the fact of their having been used both by Sir John Herschel and Mr. William Crookes, was made public not less than *thirteen months prior* to the date of the patent, and within a month or two of that announcement, bromized collodion was extensively employed in London, Liverpool, and elsewhere.

We have noticed that the same parties lately obtained a patent in this country for a photolithographic process, and this brings us to another observation: how is it possible, considering the number of patents granted in which the use of bichromate of potash with organic matter forms the essential principle of action, that more than one of them can be good; and if this be the case, why are applicants for letters patent involving the principle mentioned allowed to obtain them? Again, if the use of bichromate of potash with organic matter be not the exclusive

right of any one, then it follows that the most trifling variation in the *modus operandi* is sufficient to evade the infringement of a patent.

A third instance we may cite, in a patent recently obtained, viz., in June, 1857, by Messrs. Glover and Bold, of Liverpool, for what they please to term "the extended uses of photography as applied to dials, tablets, and pictures," these said "extended uses," consisting in the employment of *opal glass*, instead of the ordinary colourless kind, and the rendering the surface slightly dulled by the use of fluoric acid. Now if such obvious trivial variations can be the subject of a patent, it is by no means difficult to show how any infringement may be avoided while the same end is attained; but what renders the matter still more ridiculous is the fact that a patent was granted for *precisely the same thing* to Mr. John Ure, of Glasgow, in 1854.

It may be contended, that if a person obtain a patent improperly, he is liable to have it rendered void, and thus suffer damage; but granting this to be the case, what reparation is made to the public? If a photographer, knowing that the subject of a patent is and has been for some time public property, determines to act upon that knowledge and use the privilege, he renders himself liable to an action, to which he would not have been subject but for the improper concession of letters patent. It is not to the purpose whether he gains his cause or not eventually, he ought not to be placed in such a position by the wrong doing of another.

We cannot but entertain the opinion, that it would be well worth the while of photographers generally to attempt to devise some kind of supervision relative to the granting of patents upon all matters photographic.

We are rejoiced to find that our photographic friends in Glasgow have determined upon holding an exhibition in that city in April next, and we have much pleasure in affording space for the regulations adopted, which will be found in another column.

There are many earnest workers in Glasgow, and it is a thousand pities that the Photographic Society there should have been dormant for so long a time as has been the case. We trust that it will however now rouse itself like a giant refreshed. We recommend our professional brethren especially to respond to the invitation of the Glasgow Society, as we feel assured that their works will be duly appreciated.

We have been asked to give a description of the box recently brought out by M. Marion, of Regent Street, for the preservation of sensitised photographic paper without deterioration.

It will be as well to state all that we know of the subject. At one of the meetings of the French Photographic Society, a gentleman exhibited a box for which he claimed the quality of preserving, unaltered, the sensitised printing papers, but as he proposed to obtain a patent for the same, declined to give any information relative to its construction and mode of operation.

MM. Davanne and Girard, whose labours with regard to the investigation of the phenomena connected with photographic printing are so well known, in the course of their experiments, sought for a solution of the problem of the rapid deterioration of sensitised paper even when not exposed to the light, and found it due principally to the presence of moisture, favouring chemical action between the organic matter contained in the paper and the free nitrate of silver, with which it was impregnated. Under these circumstances, they very naturally concluded, that if the paper were properly protected from the access of moisture, it would keep good, if not for an indefinite, for a very long time at least.

In order to attain the end in view, these gentlemen recommended the use of tin boxes with closely fitting lids, and with the insertion of some substance greedy of moisture, in order to absorb even the small quantity enclosed with the air in the said box. The material selected in preference for this object is the *chloride of calcium*, one analagous in composition with the well known photographic chemical—the chloride of barium. For the purpose of dessicating the atmosphere contained in the box, the salt should be previously fused, which renders it more absorbent of moisture. It is easily prepared by the action of hydrochloric acid upon marble, and crystallising the compound formed, subsequently subjecting the crystals to a high temperature to drive out the contained water of crystallisation.

Acting upon the hints thrown out by the eminent French chemists above indicated, M. Marion has constructed a rectangular box of tinned iron, that shown to us being of sufficient capacity to contain many half sheets of Canson's or Marion's paper without being folded. Its dimensions were therefore about twenty inches long, twelve inches broad, and one-and-a-half inches thick. The lid is at *one end*, hinged to the box, and made to fit over tightly, and internally one of the large sides is seen to be covered with a kind of canvas, held in place by a fillet of tin soldered to the box itself—the purpose of the canvas is doubtless to confine the chloride of calcium, and yet allow it to exert an effect upon the air contained in the box.

We have heard that the form of box first adopted was cylindrical, having a loose smaller cylinder of perforated zinc, to contain the chloride of calcium, around which the excited papers were rolled.

We think that for amateurs a japanned cylindrical box would be most convenient, the length of which should be about an inch or so greater than the breadth of the papers desired to be preserved. The lid may be hinged or not, but must fit closely. *In the lid* a store of chloride of calcium may be readily confined, by a ring covered with some textile fabric, and the chemical can thus be easily renowed from time to time. Of course the papers must be loosely rolled up before insertion.

It is not improbable that with a little care the tin box without any chemical whatever, may be sufficient to preserve the sensitive papers sufficiently long for all practical purposes.

At the last meeting of the Photographic Society, we were shown by Mr. Rippingham an interesting specimen, produced by that gentleman, of a *transmitted positive* upon glass, taken direct in the camera from an engraving. It was of large dimensions, about twelve inches by ten inches, and seemed to possess due gradation of tone. The production of direct transparent positives of this kind was mentioned in our last number by our Australian correspondent, but whether the one shown by Mr. Rippingham was effected in a similar manner to that then described we are not aware, as the gentleman alluded to acted upon "strict conservative principles."

We believe, however, that he is of opinion that the process, whatever it is, may prove valuable as a means of glass ornamentation for windows, &c., and also for the production of stereoscopic transparencies without the necessity for printing of any kind.

We have little doubt, that if desirable, this feat may be accomplished without any more labour than necessary in taking negatives.

We learn from the *Shields Gazette* that, upon the occasion of the opening of the Jarrow Docks, Messrs. W. and D. Downey, of Market Place, South Shields, took a series of interesting photographs of the ceremonial, at the request of the contractors for the construction of the docks, by whom they had been employed previously in taking views of parts of the works from time to time during their progress. We are informed that these records of the opening ceremonial were taken by means of a *dry* collodion process, but for some of the plates with an exposure only of *three or four seconds of time*.

Our object in drawing attention to the facts above stated, is to show the steady advance which we appear to be making in bringing to perfection *dry* processes, a point of such importance to the art that it can hardly be overrated. It is but recently

we had to notice the feats of Mr. Kibble, of Glasgow, whom we regard as the apostle of instantaneous exposure with dry plates: his labours have evidently not been in vain; for though he has not yet communicated his ideas upon the subject, a simple display of what he has accomplished has been sufficient to set others at work in the same direction.

There are several obvious advantages in the use of dry plates for instantaneous pictures, namely,—1st, No necessity to expose them until the *exact* moment desired, as there is not any fear of their losing sensitiveness, as is the case with humid collodion. 2nd, No necessity for an assistant, as one person can do all that is required until convenient to develope. 3rd, Many more dry plates can be exposed in a given time than it would be possible to do with moist ones, and thus a larger number of records obtained of any interesting event of short duration.

We are most heartily sick of personal matters, and so far as concerns ourself individually, intend entirely to ignore such as may be directed against us for the future. We have, however, received from the Birmingham Photographic Society, a copy of a "resolution" for insertion that demands some notice at our hands. In the "resolution" alluded to we are accused of having made "an attack" upon the editor of the official organ of that Society, and then proceeds as follows, viz.:—

"This Society having always entertained the most friendly feeling towards Mr. Sutton, indignantly denies the imputation contained in the said attack (!), viz., that the Council had any intention of transferring the reports of the meetings from the 'Notes' to the 'Liverpool Journal.'"

Truly some people have a singular notion of what constitutes an "attack"— we were under the impression that our remarks were but a mild protest against "an attack" made upon *us* by the individual named by the Council. We made no such statement as is attributed to us, nor intended any such insinuation. We simply asserted, in terms somewhat vague it may be, that the "withdrawal of his objections" was a *wise proceeding*, seeing that, as he could not help himself, it was scarcely worth while his retaining them.

There are several other inaccuracies embodied in the "resolution" with which our readers will not care to be troubled, any more than they do about that noticed, but as the object of the Birmingham Photographic Society appears to be to exhibit cordiality of feeling on the part of its members towards the gentleman named, and their "antagonism" to ourself personally, much as we regret the existence of the latter circumstance, we do our best to carry out the views of the Birmingham gentlemen by publishing their remarks.

POSITIVE PRINTING.

Mr. Maxwell Lyte's Gold Toning Formula.

This formula answers equally well for plain or for albumenised paper; but it is more especially suited for the latter, which is sometimes difficult to tone by ordinary methods. The proofs, printed darker than they are required to appear when finished, are first laid to soak in a dish of clean water, then removed to a dish of salt and water, in which they must lie at least five minutes, with the view of converting any free nitrate remaining in them into chloride. The degree of strength and time of immersion in this bath are unimportant. An ounce or two of common salt to a pint of water will answer. This bath is essential to preserving the gold bath from decomposition. The latter is prepared as follows:—

Chloride of gold	10 grains.
Phosphate of soda	3 drachms.
Distilled water	1 pint.

This mixture should be neutral to blue litmus paper. The proof, so soon as it is placed in this bath, changes colour, and passes rapidly from red, through various hues of purple, to a rich black or rather grey; while the green solarised parts darken and develope their half tones in a surprising manner. The toning may be stopped at any particular point: if at the purple hue, the picture, when dry and finished, will be of a rich deep sepia; if at the black, the picture will be more inclining to black and grey. Upon removal from this bath, the proof is placed in pure water, and afterwards in a fresh solution of hyposulphite of soda, twenty per cent., where it should be allowed to remain an hour at least, then washed as usual. It loses but little of its strength in the hypo, but becomes clearer and better defined.

The principal advantages of this method appear to consist in the colouring bath being perfectly neutral, and consequently it produces no decomposing effect upon the hyposulphite, thereby ensuring greater stability for the proofs. The colour is produced solely by the gold without the aid of sulphur or other deleterious agents; and moreover, no organic matter being present in the bath, spontaneous decomposition, causing the gold to become precipitated, is avoided. The gold bath may be prepared in any quantity; the portion used must not be returned to the stock-bottle.

For proofs which require to be over-printed, a few drops of syrupy phosphoric acid, if added to the above bath, will bring out the details of the deeply solarised parts: but then more than ordinary care is required in washing the proof before it is put into the hypo, to which a little carbonate of soda or chalk is a useful addition. The phosphate of soda in the above formula may be replaced by one drachm of bi-borate of soda—common borax.

DARK SLIDES *versus* LATENT LIGHT.

By John Glover.

There are, without doubt, greater enemies to the photographer than are ever dreamt of in his philosophy, but I dare venture to assert that the subtle agent by which all his results are obtained is one that presents the greatest variety of phases, and is the most dangerous because least understood. It therefore behoves us, who wish to advance the interests of our art, to take up this most difficult and delicate subject, to investigate the facts in all their bearings.

A few months ago, the startling theories of M. Nièpce de St. Victor, and still more wondrous results, took the world by surprise, but we now hear whispers of failures in other hands but his, and by some, experiments in "bottled up light" have been placed in the category with the bottle tricks of other conjurors. Probably, if it had not been for an accidental stumble which precipitated the writer into the well, at the bottom of which truth is said to be concealed, the reader would not have had his patience tested by scanning over the attempt to embody these ideas.

The directions given by the fathers of photography, were, "take every precaution to shut out every ray of white light from your operating rooms, cameras, dark boxes, &c., and in manipulating use very little of the yellow," but since the astounding discoveries previously alluded to, our caution should extend still further than that of our predecessors when light is in question. Take care that in an unguarded moment he does not enter your apparatus, and lurk in a dark corner, to play fairy-like pranks, dashing out with his invisible brush the pencillings of his visible brother on the outside. Perhaps our scientific friends may think that the writer is *drawing* on their imaginations, but to speak in language very commercial, but very unphotographic, to make the draft *valid* I will at once *endorse* it with something practical.

My experience during the past season was principally in dry collodion, which in my humble opinion is *the* process for the professional tourist or persevering amateur. In working with dry plates, it was my custom to prepare them in the evening, and when dry to place them in separate dark slides, expose them during my rambles on the following morning, the plates remaining in the slides till the evening, when I developed them; and now I come to the remarkable phenomenon which it is my present object to describe.

On most of my negatives, a dark but regular line could be observed, running from end to end, not far from the upper edge of the plate; this was most distinguishable when foliage or other shadowy substance came within its range. For a long time I was unable to trace this to its source, looking in vain for some minute crevice in my slides or camera, till at last it struck me that the appearance was due to *latent light*, and my suspicions, as I shall presently prove, were not groundless. The dark slides were new and the same as are commonly used, having a lifting shutter with a hinge to fall flat on the top of the camera during exposure. The hinge in this instance was constructed of light-coloured leather, and being lifted entirely out of the slide, would be exposed to the full glare of the sunlight, and again drop unto its former position close to the sensitive surface, though of course not in contact, giving off the latent light which it had just absorbed. On

developing some hours afterwards, the first deposit of reduced silver was along that portion of the plate that had been in a line with the light-charged hinge, showing that of the two influences the action of the latent light had been the more energetic.

Let me ask, how many dry plates have been ruined, and perhaps processes discarded, from want of proper precautions being taken in keeping out or carelessness in admitting this invader? Perhaps we have drained our plates against a whitewashed wall, or other light-absorbing substance, or rested them on white blotting paper, which before the intervention of our yellow medium had been subjected to the continued influence of actinic light. May we not legitimately look in a new direction for many of those additions, not improvements, to our pictures, to which the most skilful manipulator is liable and for which he has never been able to account?

I would urge in conclusion, that every one who has time and talent at his disposal, should continue the research that M. Nièpce has opened up, and with such an instance as that I have described before us, let us not form hasty conclusions and discard theories, which have been the result of well directed experiment, because they do not at once prove successful in our hands. I had nearly omitted to state, that some of my negatives have a peculiar circular transparent mark, which could always be traced to one particular slide, and corresponded with the head of an iron screw in the shutter. I satisfied myself there was no contact, and, strange to say, the screw head is in such a position as never to be exposed to the light. I am at present at a loss for a solution of this phenomenon.

PHOTOGRAPHY ON PAPER.—QUICK PROCESS.

By M. Vernier, Jun.

Photography on paper has gone somewhat out of fashion since the introduction of collodion, and for very good reasons. Collodion is quicker and yields sharper pictures. Still, if we compare two positive proofs of the same landscape, of large dimensions, the one taken on collodion, the other on negative paper, we shall perceive that the latter is richer, softer, more aerial, and with more depth; in fact, more artistic than the first. This difference in results has induced me to make new experiments with paper, with the view of obtaining the sharpness and rapidity of collodion.

The method which I now submit to the attention of your readers will, I hope, fill up that gap, and restore negative paper to the high place it once occupied in photographic processes.

As a basis for my new experiments, I have selected the gelatine employed by M. Baldus, one of our most accomplished artists. This substance does not produce any change in the nitrate of silver bath, nor impair its limpidity. In following his method I obtain greater finish by sizing the paper before iodising it, and greater rapidity by immersing it in an ethero-alcoholic iodide bath before sensitising; besides these two operations, which are not in M. Baldus's process, I develope the image with sulphate of iron, which, as is well-known, is the most energetic developing agent.

I select a paper of very equal texture, marking one side with a pencil, then float it on the following for about two minutes:—

Rain water	12 ounces.
Gelatine	80 grains.

When removed from this bath, the sheets of paper are suspended by an angle and allowed to drain and dry; then placed in a portfolio and pressed flat.

Iodising — Take of the above gelatine solution 12 ounces.

Iodide of potassium	3 drachms.
Bromide of potassium	36 grains.

Warm the mixture, and when the ingredients are dissolved, filter through muslin into a dish kept warm on a water bath. In floating the paper on this solution, the usual care must be taken to avoid bubbles, and the placing the gelatined surfaces in contact. When dry, they must be kept in a box in a dry place.

This double preparation gives a greater fineness to the proofs, renders the paper unchangeable, preserves its whiteness, and keeps it free from spots, because the iodine is not in contact with the paper, which often contains substances that neutralise its action, and produce spots upon developing, which injure the proof irreparably. The preliminary sizing is then of undoubted utility.

Sensitising — To sensitise this paper I take it by a corner with a pair of horn forceps, and immerse it in the following solution:—

Ether	1 ounce.
Alcohol	3 ounces.
Iodide of potassium	130 grains.

The paper imbibes this solution. If I intend to use it *wet*, I float it immediately on a collodion negative bath; after a contact of two or three minutes I remove the paper at once to the camera slide. If I use the paper when dry, it is only necessary to suspend it in the dark, and preserve it out of contact of the atmosphere.

Exposure — The time of exposure in the camera is nearly the same as with collodion. I have observed that when the sensitising bath is acidulated with acetic acid, the paper becomes more sensitive. In every other process the presence of acid retards the luminous action, while in this it has a contrary effect. The acid opens the pores of the gelatine, causes it to swell, and consequently renders it more permeable to the chemical action of light.

Developing — Upon removing the paper from the camera I immerse it in a mixture of alcohol and water; then pour over it a filtered solution of sulphate of iron, which has already been used with collodion. The image appears immediately in all its details. If from too little exposure it is deficient in vigour, I let the paper drain, then lay it upon a glass plate, and pour over it, from an upper corner, a weak solution of nitrate of silver, and then apply, for the second time, sulphate of iron. This simple method of strengthening an image will give all the intensity desired.

With a good stock of iodised papers the manipulation of this process is very simple, requiring but little time, and no new complication of baths; but its chief recommendation consists in the facility it offers for obtaining very good proofs by the dry method. With reference to what I have said above, relating to drying the iodised papers by suspending them in the air upon removal from the iodising solution, I may remark that it is not absolutely necessary for the dry process. I prescribed it because I found it convenient to operate in that manner. Usually, I prepare eight to ten sheets at once, and by the time I have floated the last, the first is sufficiently drained to admit of its being placed on the nitrate of silver bath. After the two washings that must follow the sensitising of the papers, the other operations are the same as with the wet method.

One day I took two pictures of the same object, and treated one with sulphate of iron and the other with gallic acid. The proof treated with sulphate of iron developed rapidly, and yielded a very good picture, as usual; that put into the reducing bath of gallic acid gave, after the lapse of half an hour, no signs of a picture; yet I was sure the paper was properly exposed in the camera, and with exactly the same time as with the other proof developed with sulphate of iron. To accelerate the development of the image I added some drops of nitrate of silver to the gallic acid, and waited another hour without obtaining any results. At length, impatient with waiting so long for a picture, I took a bottle containing an old bath of nitrate of silver, which had served for many experiments, and contained ether, alcohol, iodides, acids, and a little sulphate of iron. I decanted the clear portion of the liquid, and then poured a quantity of it into the gallic acid solution. My attention being engaged, I left the proof to itself, as an experiment from which I did not expect much. Upon looking at it an hour afterwards, I was surprised to see the picture completely developed; but what surprised me still more was, that the developing bath had undergone no change.

I ask my fellow photographers and chemists, what substance in the old bath was it that kept the gallic acid in good condition? and I beg also to submit other questions.

Why is collodion the most rapid of all photographic agents?

Is this rapidity due to the pyroxyline which enters into the composition of collodion, or is it due merely to the two substances dissolved in it?

Without presuming to decide upon these questions, I venture to atttribute to the ether and alcohol combined this accelerating property. In the method described above it is shown that the ether and alcohol, being imbibed by the paper instantaneously, facilitate the combination of the photogenic products, and consequently opens a freer access to the chemical action of light. These substances are, therefore, two powerful agents in photography.—*La Lumière.*

GLASGOW PHOTOGRAPHIC SOCIETY.

Exhibition Regulations.

The following Regulations have been laid down for intending Exhibitors at the forthcoming Photographic Exhibition, to be held in the Gallery, No. 67, Buchanan Street, Glasgow, during the month of April, 1859.

1. Every description of Photographic Pictures will be admissible, but not more than twenty portrait specimens to be admitted from any one exhibitor. It is recommended that all pictures be framed and glazed. The name of the subject, the process, the artist, the owner, and if for sale, the price, to be marked upon the back of each picture.

2. A list of the photographs sent must be enclosed in the case, and a duplicate list forwarded by post to Mr. Barr, the Acting Secretary, No. 1, Renfield Street, Glasgow.

3. Pictures touched by the brush to be so described.

4. A commission of ten per cent. will be charged upon all sales of pictures.

5. It is requested that all works intended for Exhibition, be sent carriage paid, to the Rooms, No. 67, Buchanan Street, on FRIDAY the 25th, or SATURDAY the 26th March; and, at the close of the Exhibition, they will be carefully repacked and returned carriage free.

Meetings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A MEETING of the above Society was held at the Literary and Philosophical Society's Rooms, on Wednesday, the 2nd instant, Mr. NIELD in the chair.

A large collection of photogalvanic engravings, by Mr. Paul Pretsch, were exhibited to the meeting by the SECRETARY.

Mr. SIDEBOTHAM exhibited one of Captain Foulkes's compact cameras for taking pictures 9 × 7.

Mr. PARRY exhibited a very compact and simply constructed camera, designed by himself.

Mr. KERSHAW exibited a stereoscopic camera, and dark box for plates, containing a yellow glass window, so that the plates might be seen without injury from light.

Mr. SIDEBOTHAM called the attention of the meeting to this arrangement, as he thought it would be of great importance when passing the custom-houses, and said he should adopt the idea, having previously thought of the subject. He said he had been several times annoyed by the custom-house authorities wishing to open his dark box.

The CHAIRMAN called the attention of the meeting to a very satisfactory negative, taken by Mr. Patterson, simply with dry collodion on the coating of gelatine, as recommended by Mr. Dorrington.

Mr. SIDEBOTHAM read a letter he had received from Mr. Hardwich, who stated that he had succeeded in making a very suitable collodion for the dry process. Mr. Sidebotham also remarked that he had lately been through the London Exhibition, and was much disappointed to find a great scarcity of collodio-albumen pictures, and few of those exhibited being good ones.

Mr. WARDLEY, however, stated that he had seen the Exhibition, and had observed some very good collodio-albumen pictures.

Mr. SIDEBOTHAM made a suggestion to the meeting that an album should be procured, and that each of the members of the Society should send his portrait for insertion, as he thought it would form a very interesting record. The suggestion was approved of by the meeting, and a resolution passed that the Honorary Secretary be authorised to obtain a suitable book for the purpose.

Mr. BROTHERS promised to send a copy of the portrait of the Lord Bishop, the President of the Society, and volunteered to take the portraits of any members gratuitously who would call upon him at his rooms, and it was proposed that a portrait be obtained of the late Mr. Archer and other eminent photographers.

Mr. SIDEBOTHAM exhibited a large lens, by De Rogni, which possessed several advantages: it was possible, by changing some of the glasses, to arrange the foci to various lengths, and instead of the troublesome screws, bayonet joints were supplied, which were highly approved of by the members.

After a vote of thanks to the Chairman, the proceedings closed.

LONDON PHOTOGRAPHIC SOCIETY.

THE ordinary general meeting of the above Society was held on Tuesday, the 1st inst., P. LE NEVE FORSTER, Esq., V.P., in the chair.

The minutes of the last meeting were read and confirmed.

Mr. BISHOP tendered a notice of motion, that the Council should be required to send to every member a printed copy of the accounts of the Society, and a statement of the names in which the funds of the Society are invested.

The CHAIRMAN decided that Mr. Bishop's motion could only be made at an annual general meeting of the Society, or at a special general meeting, convened in pursuance of a requisition signed by twenty members; the only business of the ordinary meetings being simply the discussion of matters connected with the art and practice of photography.

Mr. RIPPINGHAM, on the part of the Council, denied any desire to conceal the accounts; they were laid before the members present at an annual general meeting, and an extract printed in the Journal of so much as is generally considered sufficient. An application by any member to the Council for permission to inspect the books had never been, or ever would be, refused.

Major COOPER, after a few prefatory observations, read a paper on *The use of Malate of Silver in Photographic Printing*, illustrating the same with specimens.

Mr. HARDWICH was exceedingly glad of opportunities for the discussion of new printing processes. It struck him, however, that there would be a difficulty in Major Cooper's; because, even if one employed *pure* bicarbonate of potash or soda, he would not secure the absence of chloride of silver, owing to the presence of chlorides in the fabric of the paper; and in attempting to get out the malate of silver, by simple malic acid, the chloride of silver would be left behind. He thought all processes for fixing albumenised proofs without the use of hyposulphite of soda radically defective. He had tried ammonia, and did not succeed in perfectly fixing a picture upon albumenised paper, although he had accomplished it upon plain paper.

Sometime since, he had spent a great deal of time, and took great trouble, with malic acid, and found it liable to be contaminated with other substances—there was a difficulty in obtaining it free from oxalic acid, and acids of a similar kind, which pervade vegetable substances.

He (Mr. H.) was not prepared to understand, that the reduction by light by the Major's process would be sufficiently rapid; for although there is a certain amount of sensibility in his compounds, especially when the amount of free nitrate of silver is large, still the process must be slow and the prints rather faulty. He (Mr. H.) usually found that without the aid of chloride of silver he could not obtain a rapid and intense reduction on the parts exposed to the sun's rays; and, therefore, did not at present imagine that Major Cooper's process could be successfully carried out as described.

Major COOPER called attention to the first part of the process—viz., the floating in *distilled* water, to prevent the formation of any chlorides in the paper. He admitted his printing was rather slower than the usual processes, although no one of the prints upon the Society's table had been exposed more than an hour or an hour and a-half.

Mr. HANNAFORD handed to the Chairman some slips of paper as bearing upon some of the remarks made by Mr. Hardwich, and stated that they were printed by the ordinary process upon albumenised paper, with the exception of the omission of the salt, and consequently the absence of chloride.

Mr. SHADBOLT stated that Mr. Hannaford had overlooked the simple fact, that no paper could be obtained which was perfectly free from chloride, and that, consequently, some portion of chloride of silver must be formed. He thought that Mr. Hardwich was a little too fearful that ammonia would not dissolve out all the chloride of silver. He (Mr. Shadbolt), as a member of the printing committee, made many experiments in that direction, and went to the extent of subsequently soaking a print so fixed in a weak solution of hydrosulphate of ammonia, which did not blacken in the lights, proving unquestionably that all the chloride of silver had been removed. The only real objection to the use of ammonia, was its suffocating effluvium; but if it be a *sine qua non* to get rid of hyposulphite of soda, the means of so doing are in our power. It struck Mr. Shadbolt, that by using bicarbonate of ammonia, the ammoniacal fumes would be avoided. By bicarbonate of ammonia he meant the sesqui-carbonate after exposure to the air, which thus lost its pungent quality. He should like to know whether chloride of silver is soluble in a solution of this salt.

Mr. HARDWICH stated that it was not the chloride of silver but the oxide of silver which he feared. The oxide of silver associated with the albumen, or with the animal matters in the paper.

Mr. SHADBOLT begged to be allowed to make the further remark, that Major Cooper was a little out in his chemistry, when he stated that carbonate of silver is soluble in malic acid. It was not that the carbonate of silver is soluble, but simply that the malic acid displaces the carbonic acid; and hence malate of silver is formed.

Major COOPER stated that the carbonate of silver remained in suspension a considerable time, and that the whole was eventually perfectly dissolved, and that what remained in the paper was perfectly soluble in boiling water. The Major then read a memorandum which he had made, to the effect that malic acid must not contain tartaric acid, lead, nor colouring matter; that malic acid does not precipitate bright metallic silver from the nitrate, as had been stated, but bright, highly refractive crystals, so brilliant that they might easily be mistaken for metallic silver spangles; but

they could easily be dissolved in boiling water. The Major stated, that he had precipitated some nitrate of silver by malic acid, and observed that which at first sight he considered metallic silver falling; but upon close inspection, he found it to be a precipitation of crystals, which he afterwards boiled, in a Florence flask, with some water, and the solution was perfect. He thought when the carbonate of silver was dissolved, though a malate of silver remained in the paper, it was removed by boiling.

Mr. SHADBOLT thought that Major COOPER had mistaken the point which he (Mr. Shadbolt) had alluded to. The Major had stated that *carbonate of silver* was soluble in malic acid; but he must have meant, not that carbonate of silver, as a carbonate was soluble in malic acid, but that the malic acid displaced the carbonic acid, forming a malate of silver, which is soluble in water.

Major COOPER: "Just so."

The thanks of the meeting were then accorded to Major Cooper.

The SECRETARY then read a letter from Mr. Hardwich, asking for a committee of examination to inquire into the doubtful points in connection with the manufacture of collodion, and offering, if it were accorded, to lay before it, unreservedly, all the minute details of his experience in its preparation.

The SECRETARY stated that the council had considered Mr. Hardwich's proposition, and resolved that a committe of the Society should be appointed to examine and report on the various formulæ for making collodion, and that members of the Society and makers of collodion be invited to send samples of collodion, such samples to be accompanied, unconditionally, by a full statement of the manner of its manufacture.

The SECRETARY then read a letter from Mr. Penney, of Cheltenham, accompanying some specimens of carbon printing by Mr. Pouncy's process, in which sepia, indigo, and other pigments were substituted for carbon in a state of mechanical division.

Mr. FRITH stated that he had tried the carbon printing, as had also several of his friends, without any success, and they had all given it up as comparatively hopeless for general purposes.

Mr. SHADBOLT had not before heard of Mr. Hardwich's suggestion, and did not quite understand exactly what had been decided upon. The French Photographic Society had long been in the habit of referring to a sub-committee, certain questions upon which it was thought advisable to pronounce an opinion, the names of the members of the sub-committee being published, and that system had worked well. If he did not misunderstand Mr. Hardwich's suggestion, it was, that a committee should be formed for the purpose of testing collodion by different manufacturers, who might be willing to subject their collodion to the test, and give unreservedly their formulæ for its production to the committee. The proposition appeared likely to be beneficial to the photographic art, as it would probably clear up several obscure points connected with collodion; for instance, he might mention, that some persons entertained the opinion, that collodion, containing a great mass of pyroxyline, is most sensitive, while others consider, that in order to be extremely sensitive, it must be exceedingly thin; and it may turn out that both parties are right under certain circumstances.

There was another very great difference of opinion existing of very considerable importance, now that the dry processes were, as it were, upon their trial; and the difference arose upon the question, whether the collodion made with acids at a high or a low temperature is the best. Mr. Shadbolt's object in alluding to this matter was because it very frequently went abroad, that if a committee were formed to investigate any particular point, it was apt to be thought that everything connected therewith, submitted to the Society, must of necessity be tested by the sub-committee. The committee should confine itself to testing those samples which the makers requested to be tested.

Mr. HARDWICH confessed he did not precisely understand Mr. Shadbolt's observations; but if he had intended to have said that the committee should examine the great number of specimens of collodion that may be sent to them, he (Mr. Hardwich) thought that it would be utterly impossible for the committee to do the work; but he, having experimented upon collodion for two years, and collected a mass of information which had never been published, had by degrees, and by the assistance of many friends, arrived at one formula, which was on the whole a sound working formula. He did not think it an unfair proceeding to ask the Society to appoint a committee of practical men to examine it, and to say whether it will do what it is professed to do. He would withhold nothing, and would describe exactly how his collodion is to be made, and what precautions are to be used to secure the result. He said, as he had offered this to the Society, he thought that he was entitled to the commission to examine this collodion alone. By the collodion he meant the pyroxyline, and did not refer to the iodide or bromides of cadmium, &c., but simply to the pyroxyline, and considered the production of that substance to be one of the most complex chemical problems, as there were so many peculiar changes which take place in its manufacture. It is a problem which no single person can solve, and can only be accomplished by a combination of persons. He had letters from India, and from almost every part of the world, telling him in what condition his pyroxyline had arrived, and how it had done its work. He thought he was entitled to a committee upon this single point.

The CHAIRMAN stated that the form of the resolution of the council for the appointment of a committee did not quite agree with Mr. Hardwich's views. The committee would be formed for the purpose of considering those collodions, and those formulæ for making them, which individuals and manufacturers and others may desire to lay before it, not confining themselves to the one collodion of Mr. Hardwich, but taking a broader basis of operations.

Mr. SHADBOLT stated that it was in consequence of the resolution of the Council, and the suggestions of Mr. Hardwich not quite tallying, that he had spoken upon the subject.

Mr. SEBASTIAN DAVIS stated, that he had, within the last week, carefully examined the formulæ laid before the public for the manufacture of pyroxyline, and followed precisely the formula which Mr. Hardwich had mentioned in his work; and found, that by following that exactly, with the materials he had used, instead of obtaining a satisfactory pyroxyline at the temperature there stated, the cotton dissolved more like lump sugar than cotton; and it appeared that the recommended quantity of water was decidedly in excess. He merely stated this, to show why it was desirable, that when gentlemen communicate details, they should have an opportunity of defending their assertions. He knew full well that many communications had been made to the Society, and yet gentlemen with a considerable amount of photographic knowledge have not succeeded in following out the views held out, although they appeared to be exceedingly explicit and clear; therefore, he, for one, would advocate the appointment of a working committee, to test the particular formula laid before the meeting. Under these circumstances, there must be a full, clear, and precise description of the whole process, from the commencement to the end, so that any operator shall be able to succeed in the same manner; because it is known, that science is based upon exact principles, and all must arrive at the same result by following the same course.

Mr. HUGHES rose to call attention to the important question involved. Over and over again complaints had been made as to the inutility of societies like this, because they have not undertaken such duties as that now proposed; but the question was, whether the time had arrived when it had become desirable for this Society to pronounce an opinion upon a certain subject? Was it desirable, from time to time, when any particular novelty was presented, to investigate the merits of that novelty, and express an opinion upon it? Mr. Hardwich thought he had a collodion which would settle the much-vexed question as to a definite formula for this usually unstable substance, and was willing to communicate it to the world, with all his experience, upon the condition that the Society shall pronounce an opinion. If he (Mr. Hughes) understood Mr. Hardwich rightly, he would like this committee to test the collodion for all the various contingencies for which collodion is used—for interiors, for exteriors, for still life, and for portraits — while the resolution of the council is, that a committee be appointed to investigate the merits of collodion generally made by any one, upon the condition that their formulæ be published. If Mr. Hardwich's proposition did not go to that extent, it fell to the ground, and a new one is taken up, which it appeared the council were not invited to entertain.

Mr. RIPPINGHAM stated that Mr. Hardwich, himself one of the Council, was present, and did not dissent from the extended resolution.

Mr. HARDWICH said he had no possible objection to the alteration, as proposed, and should be most happy to modify the original proposition, to bring it in accord with the resolution. With reference to the remarks of Mr. Davis, he should be happy to reply, but the question was, whether it would be desirable now to discuss chemical formulæ, which is a difficult thing to do. With reference to the cotton simply, it was known that there were twenty-six different kinds of cotton; he used the best and finest he could get, and he could say, that flax might dissolve in an acid mixture which did not dissolve cotton, and white China grass would dissolve in an acid that would not dissolve cotton. It might be found eventually, that he had not satisfactorily answered every question with reference to collodion, but he believed that he was prepared to publish more than had ever been published up to the present time, and that it would not be doing justice to himself to refrain from bringing his results forward.

Mr. HUGHES rose in explanation. He had thought that there was an antagonism between the resolution of the Council and the proposal of Mr. Hardwich, and concluded by asking the Council to name the committee.

The CHAIRMAN stated that there had not been time at the last meeting of the Council, but that would be done at their next meeting.

Mr. SEBASTIAN DAVIS thought he should be scarcely in order in going into the chemical composition of pyroxyline, but might do Mr. Hardwich the justice to say, that in the following page of his book, he distinctly asserts, that he cannot always be depended upon in minute particulars; because he there asserts, that he lays in a very large stock of sulphuric acid, ascertains by direct experiment the correct quantity to be used, and follows out the result with the remainder.

The CHAIRMAN stated that Lord Lyndhurst had procured the appointment of a committe in the House of Lords upon the subject of artistic copyright, and the Council of the Society had appointed a committee to attend and lay evidence before the House of Lords, with reference to its bearing upon the interest of photographers.

Her Majesty, the Prince Consort, and two of the Princesses visited the Exhibition a few days ago. Her Majesty expressed great gratification at the success attained, and his Royal Highness, the Prince, made a suggestion to the Society, which the Chairman thought a valuable one, and the duty of the Society to undertake, namely, to get together a complete and satisfactory record of what has hitherto been done in photography, and make a collection of early photographs, to show the progress which has been made from the earliest to the present time — for the future there could be no difficulty; but with regard to the past, the Society must rely upon its members to send in such specimens as will illustrate the point desired, and the Society will place them in proper custody.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on Monday, the 21st ultimo, at the Golf Club House, Blackheath, the President, J. GLAISHER, Esq., in the Chair.

The PRESIDENT commenced the business of the evening by calling the attention of members of the Society to the Photographic Soirée which it was in contemplation to hold.

It was moved by Mr. HARDING, seconded by Mr. KNILL, "That such soirée be held."

A Committee was proposed by Mr. WOOD, seconded by Mr. LEDGER, for the furtherance of this object, composed of the President, Vice-President, Treasurer, and Secretaries, *ex officio*, Mr. Bennock and Mr. Wood.

A letter was read by the PRESIDENT from F. Haes, Esq., dated Sydney, relative to the deterioration of dry collodion plates, which he wished communicated to the Societies at home.

The PRESIDENT exhibited some photographs taken in the neighbourhood of Linton, North Devon; Mr. WOOD some views in the South of France; Mr. KNILL some fac-similes of frescoes, from the Campo Santo, Pisa.

William Porter Knightley, Esq., was duly elected a member of the Society. The meeting then adjourned.

LIVERPOOL PHOTOGRAPHIC CLUB.

ON Tuesday evening, the 1st instant, the third evening meeting of the above newly-formed Club was held at Mr. Keith's Rooms, Lord Street Chambers: there was a full attendance of members, and several novelties were exhibited.

Mr. SCOTT, of Birkenhead, explained the contrivance of a very excellent photographic pack, combining the convenience of both tent and barrow. A large box, when opened, presented table, front, and roof; four legs were speedily screwed into this, and a drapery attached soon enveloped the whole of the sitting figure of the operator, who worked with great facility upon plates of large size. When it was to be removed, the box, repacked, was placed on a small carriage with two wheels and an iron handle, altogether about as large as a child's perambulator, minus the third wheel.

What was especially commended was a water bottle of gutta-percha. Being flat, it was slung round the shoulder, and having a wide mouth to it, a large cork, pierced with two holes, was inserted; in one a bent tube was placed, in the other a long slender brass one; on inclining the bottle, the air entered the brass tube, and being smaller than the exit through the bent tube, the flow was even, soft, and continuous, like a stream of oil, and could be stopped with all the facility of a tap, by simply pressing the thumb on the top of the air tube.

This gentleman's negatives were remarkable for their depth of shadow, minute richness of detail, and excessive cleanness of their whole surface.

Mr. COREY exhibited his first specimen of toning by Mr. Hardwich's new formula for a gold bath with citric acid, and used warm. He reminded those present that the highly albuminized paper is very desirable on account of the brilliancy of its general effect, at the same time it is remarkable for the fidelity with which it brings out all the charms of the intermediate portions of half tone and lighter shadows, though objectionable from the fiery red, or to at best, brown brick-dust hue when finished. This is entirely obviated by the use of the bath in question; for any amount of inky blackness can be thus obtained. The specimens were highly commended for the extreme whiteness of the unprinted paper, and the rich purple blacks of the deep shadows, while the minuter portions were so well preserved.

Mr. COREY mentioned that Mr. Forrest, who was unavoidably absent, had been operating most successfully on a favourite project, in which he had displayed a considerable amount of enterprise, viz., the permanently burning photographs into the surface of glass. That nothing daunted, but rather stimulated, by his former unsuccessful efforts, he had determined to take advantage of the known changeable qualities of certain minerals when under fire, and expected to produce great novelties from his present experiments. Mr. Corey called upon those well versed in chemistry, and changes of metallic oxides in the furnace, to aid Mr. Forrest in his labours, when Mr. J. Glover and Mr. Keith were appointed for that purpose.

Mr. CAUTY exhibited some new specimens of Ross's lenses of the orthoscopic character, with the shifting diaphragm; and after a very animated and social evening, the meeting separated at a late hour.

Letters to a Young Photographer.

No. VI.

MY DEAR EUSEBIUS,

By this time you doubtless have obtained a lot of pretty good specimens of positive printing. Your proofs should be quite free from a sulphur-yellow in the light, while the tones of the picture may range through all the hues of bistre, umber, sepia, or Indian ink. What are termed the violet and purple hues are the most admired; but, as artist, you will not forget to tone your proof with such a colour as best harmonises with the subject of the picture, and for this object I will just give you a few hints. The richness of colour may, in landscapes, &c., be in the inverse ratio to their interest. For instance, suppose your picture represents a rough, rocky region, bold in feature, and not very picturesque for want of the poetic element, such a picture will look best if toned of a warm umber hue. For diversified landscape scenery, I prefer a red violet hue, or something of the mulberry, which may range to the different tones of sepia and bistre. For sky and water pieces, I prefer the deep purple hue; while for portraits there is a peculiar neutral brown, difficult to describe, which yields a very fine harmonious effect. You will doubtless encounter a difficulty that has perplexed me very much, which is, that certain negatives obstinately refuse to yield the hues you desire, no matter how you print them. I have some negatives which, when examined carefully, cannot be distinguished from others, but from which it is impossible, in the usual way of printing, to obtain any but reddish-brown pictures. This is an anomaly which at present I cannot fully account for. If I work half a dozen negatives of the same object, looking in every respect alike, expose them all at the same moment, with paper prepared under exactly similar circumstances, so that you would expect the positive proofs to be identically the same—yet I can point out, at first sight, the individual negatives from which they are printed, by the variations in colour. And this is not the accident of the day or of the hour, but occurs with unvarying regularity. Thinking that some of these negatives required longer exposure to produce the violet and purple hues, I tried what that would do; still they did not yield the same tones as the others.

Now this result need not trouble you much. I mention it but to guard you against perplexity and disappointment, in striving to attain the unattainable. There may be something in the quality of the negative that gives such baffling results, which interferes with the chemical action of the light in passing through it; and you know that negatives themselves differ much in colour. I have negatives that are of a pale green colour, others are steel blue, while some partake of the colour of mud, and one sort is about as good as another.

I suppose you will prefer to mount your pictures yourself; at least, you ought to do so, else you will not become a complete photographer. Such a one is armed at all points, and can turn his hand to every thing. In mounting, your first care will be to trim your proofs square. For this operation you will require a very sharp penknife, a steel square, such as is used by bookbinders, and a piece of roughened thick plate glass; the size of the two latter implements will, of course, depend upon the size of your proofs. In trimming off the margins of the pictures, take the vertical lines first, and square the sides parallel with them, and then square the horizontal lines in conformity.

You can mount your pictures upon Bristol board, or upon drawing paper. I generally use a drawing cartridge paper, which answers the purpose as well as a more expensive kind. Have ready some starch-paste, made with *white* starch in preference to the blue. Mix a teaspoonful of the starch with a little cold water, adding a few grains of carbonate of soda; then pour on it half a pint of boiling water, stirring it briskly meanwhile. It should be of the consistence of cream; if it is not, put it into an earthen pipkin, place it on a clear fire and boil it gently, stirring it from the bottom with a brush.

I prefer this starch paste to every other adhesive substance; but if I have none prepared when I want to mount a proof in a hurry, I mix some dextrine with warm or cold water, and mount the proofs with that.

If you have many proofs to mount, lay them, face downwards, in a pile on your glass plate, and apply the paste evenly over the back. The paste must be applied freely, as the proof absorbs a good deal of moisture; when the first proof is covered, remove it, lay it aside, and proceed with the second as with the first, to the extent of about a dozen. Have your mounting-paper ready, and apply the first proof to the place previously marked on the paper to receive it. Smooth it down with a clean cambric handkerchief, so as to press out all the superfluous paste; then with a piece of clean wet sponge rub over all the surface of the proof and mount, and dry up the superfluous moisture with blotting-paper. By this mode of treatment *cockleing* will be avoided.

When dried, the proofs will require glazing. The best mode of putting a gloss on them, is by the rolling press; but when one is not of convenient access, then they may be pressed out with a tailor's goose, first covering the proof with a piece of fine smooth paper. If the proofs curl up after this operation, they should be put in a press or under a heavy weight, and kept there all night.

Sometimes a very high glaze is required. This may be obtained by applying a varnish composed of the white of an egg, to which a solution of gum-arabic is added; it is applied to the proof by means of a piece of sponge. Gelatine is also employed as a varnish, which is prepared as follows:—

Fine gelatine	10 drachms.
Gum-arabic	2 „
Water	12 ounces.

Dissolve the gelatine in half the water made hot, and the gum-arabic in the other half, and add them together. This varnish is also applied with a sponge. When quite dry the proofs must be rolled and pressed. A varnish which is recommended for its antiseptic and preservative qualities is composed as follows:—

White wax	10 drachms.
Oil of lavender..........................	10 „
Oil of cloves	2½ „

These ingredients should be placed in a covered pot beside the fire until dissolved, and afterwards kept from the air. A small quantity, taken on a piece of flannel, may be rubbed evenly over the proof, when a fine lustre is soon obtained by friction.

Proofs may also be varnished with Canada balsam, applied with a soft brush; or mastic, or dammar resin varnish are sometimes employed, according to the fancy or predeliction of the artist, but some kind of previous sizing is necessary. Of those varnished with wax, it may be said that it preserves the proofs quite free from spots or stains, and to that I always give the preference next to albumen.

As to the quantity of margin left on the mount round the picture there is one remark to be made — the greater the quantity of margin the smaller the images in the picture will appear; so the quantity of margin may be determined by the effect of size intended to be produced. As a general rule, the quantity of margin above and below the proof should be about one-half the breadth of the picture, that is one-fourth above and one-fourth below; the margin at the sides should slightly exceed these proportions.

If the proofs are to be kept in a portfolio nothing more remains to be done; but if they are to be framed, they must be surrounded with as simple and as small a gilt frame as possible — treated, in fact, like engravings, not like paintings. It is a common error to put engravings into elaborately carved gilt frames, which completely obscure the design, and distract the eye from the object presented to it, whereas nothing more is required than a simple gilt beading as a mere accessory ornament, and to give a finish to the appearance of the work of art.

Photographic Glossary.

Exposure — The presenting a sensitive surface to the action of light either in the camera or in the printing frame. The time of exposure is one of the most difficult things for the photographer to determine, as he possesses no ready means of measuring the degree of actinic intensity in the rays of light, hence his picture incurs the risk of being *under* and *over*-exposed. Of the two, over-exposure is the least detrimental to ultimate success.

Ferrotype — The name bestowed by Mr. Hunt on a class of pictures, into which iron salts enter as an element.

Ferrid-cyanide of Potassium — A salt commonly known as red prussiate of potass. It is obtained by the action of chlorine upon ferro-cyanide of potassium (yellow prussiate of potass), under the form of ruby-red prismatic crystals. It is employed in certain photographic processes.

Ferro-cyanide of Potassium — Yellow prussiate of potass; it crystallizes in four-sided tables, derived from a primary octahedron. It is obtained from animal refuse, such as horns, wool, hoofs, &c., by burning them in an iron pot, and lixiviating the residue with water. This salt is sometimes employed as a photographic agent.

Filtration — The method of separating insoluble matters from a liquid by means of *filters*, which consist of paper, sponge, or other porous substance.

Fixing — The means employed in photography to render the image permanent, by removing those portions of the sensitive salts unacted upon by light. The fixing agent commonly employed is hyposulphite of soda; cyanide of potassium is also used for the same purpose, with collodion negatives; also, ammonia with paper positives.

Fluorescence — A term applied by Professor Stokes to designate a property possessed by certain substances of arresting the chemical rays visible or invisible, and rendering the latter visible.

Fluoride of Silver — A compound of fluorine and silver; soluble in water. It has been recommended as a photographic agent, and is constantly prescribed in various formulæ. But in paper processes the fluoride of silver is washed out, and does not remain to produce any photographic effect. As it is supposed to possess some accelerating influence, it would, if used at all, be better to add it to the water employed in the washings.

Fluoride of Potassium — A salt composed of fluorine and potassium. It is very soluble in water. It is used, like the other fluorides, as an accelerating agent.

Fluorides — Combinations of fluorine with metals, &c. The principal fluorides employed in photography are those of ammonium and potassium.

Focimeter — An instrument invented by M. Claudet for ascertaining the chemical focus of an achromatic lens.

Focus — The place at which the rays passing through a lens unite to form an image of the object before which it is placed. In a simple lens, the visual and chemical foci do not coincide.

Fogging — A collodion picture is sometimes rendered semi-opaque over its whole surface upon the application of the developing agent by which the details are veiled or obscured. Such an effect is termed 'fogging;' it arises from deficiency of acid in the developer; from light accidently falling upon the whole sensitive surface of the collodion, or from decomposition of the chemicals employed.

Gallates — Combinations of gallic acid with bases. Gallate of lead is said to be an energetic developing agent.

Gallic Acid—An acid obtained from gall nuts, of a grey or yellowish white colour, in the form of fine needles: one

part requires 100 parts of water at 60° to dissolve it, boiling water dissolves three parts; it is much more soluble in alcohol. The solution of gallic acid readily reduces the salts of silver, especially in the presence of light, or when they have become modified by its action, which property renders it a valuable agent for developing photographic pictures.

Gelatine — An animal substance obtained from skins, bones, &c., soluble in boiling water, which upon cooling gelatinises or takes the form of jelly. Isinglass and glue are the usual forms of gelatine. It is used both in the negative and positive processes of photography.

Glucose — A name given to sugar of starch, which may be obtained by the action of boiling water slightly acidulated with sulphuric acid upon starch. It reduces the salts of silver, and may therefore be employed as a developing agent. It is considered identical with grape sugar.

New Books.

The Principles and Practice of Harmonious Colouring, in Oil, Water, and Photographic Colours, especially as applied to Photographs on Paper, Glass, and Silver Plate. By an Artist Photographer.

(London: James Newman, 24, Soho Square,
And Cassell, Petter, and Galpin, La Belle Sauvage Yard.)

It is pretty notorious now, whatever may have been the case a year or two ago, that the ordinary occupation of the miniature painter is well nigh gone. With all its faults, a photograph of a beloved relative or friend must be preferred to an indifferently executed miniature, for many obvious reasons, two of which are generally paramount with the public, viz., comparative cost and comparative convenience attendant upon the requisite "sitting." For miniatures of a higher class, such as are truly works of art, the acquisition of them is not even to be thought of by the masses of the population; their producers, therefore, have, we think, done wisely, in turning their attention to the finishing of photographs, by the aid of colour, in the style of miniature paintings.

Now, although an artist may be skilful in the ordinary walks of his profession, it does not follow, that without experience in the colouring of photographs, he could readily accomplish the feat satisfactorily on his first essay; any reliable guide, therefore, to enable him to acquire the necessary experience with a minimum expenditure of labour, must be regarded as a boon by him, and such we have no hesitation in pronouncing the work now before us.

The embryo artist will also find much valuable information, and though the work is evidently from the pen of one well acquainted practically with the subject on which it treats, no unreasonable promises of a royal road to success are held out; but by careful attention to the rules laid down, even a novice will find his path made less difficult.

There are minute technical details relating to every one of the methods usually employed in colouring photographs, and the author is evidently one who considers that a photograph is applied to its highest use when serving as a basis for painting.

There are some excellent introductory remarks relative to the nature and harmony of colours, based upon strictly scientific premises, and the whole is evidently written with the intention of communicating sound and practical information upon the subject treated of, and that in a straight forward and intelligent manner.

In a work of this kind it would be useless to attempt giving a sample of the instructions laid down, but the following extract from the introduction may serve to convey a notion of the author's style:—

"Presuming that the majority of the readers of these pages are photographers, professional or amateur, themselves producing the pictures they wish to colour, we think it desirable, at the outset, to urge upon their attention the importance of greater artistic culture than most of them have hitherto possessed, or deemed necessary. A cardinal blunder with them has been, the supposition that a good photograph must necessarily be a perfect representation of nature, and that such an imitation of nature as the photograph presented must be the highest triumph of art. Passing by, for the present, the first assumption, or for the moment for argument's sake, admitting it to be true, we must submit that nature has many aspects, but not all equally beautiful. As regards portraiture, the living model is seen in ever-shifting positions, and ever-varying aspects of light and shade, very few of which, however, it may be, would be suitable for portraiture, notwithstanding that they are all natural. That a portrait should be what some call natural does not, therefore, by any means imply that it is perfect as a picture. It may be natural, that a person should at some time wink, smirk, or frown, that he should occasionally stoop, loll, or stretch himself; but no one would for a moment dream of perpetuating these actions in a portrait. Notwithstanding, we have seen many photographic portraits in positions little better. Sitters placed upon a chair bolt upright, with head, body, and limbs in one line, a hand thrust forward sprawling on each knee, all arranged with such accuracy, that if the figure were cleft down the middle, the halves would weigh the same to a fraction! The expression accompanying this position being generally either one of the most listless fatuity, or with every muscle on the strain, the eyes glaring, and the features contracted to a most diabolical frown, the idea is conveyed, that the sitter is just gathering his energies for a fatal spring upon some victim. Others, again, carefully avoiding these enormities in arranging the sitter, affect positions of unstudied ease and carelessness, in which, however, every thing like grace or dignity is alike wanting.

"Nature, then, having such varied aspects, the aim of the true artist is to portray her in such aspects as best secure the *embodiment of character* in the model, combined with pleasing pictorial effect. It is here the painter possesses a great advantage over the photographer.

"The photographer must not only give up his favourite notion that he has only to depict nature to succeed, but also that the most perfect photograph is necessarily an accurate reproduction of nature as she is seen. The best product of the camera, unaided by art, is often very far indeed from being a transcript of nature. The principles of photography, both chemical and optical, combine to render this inevitable. The intense photogenic action of some colours, and the almost entire absence of such action in others, chemically, and the necessary undue enlargement of advancing objects and diminution of retiring ones, mechanically, combine to remove the photograph as far from nature as many imagine the painting to be; the difference being, that whilst it is the province of art to soften peculiarities, photography very often exaggerates them. The incipient wrinkle or trifling scar, which in nature is, it may be, hid by the brilliancy of complexion; the slight freckle, which to the eye varies so little from the general tint of the skin, as scarcely to excite observation, are at once searched out by the one huge cyclopean eye of the camera, and rendered with uncompromising distinctness in black and white. The red or golden tresses appear with raven blackness, whilst the blue eye, which in the photograph is as colourless as water, seems to have lost in depth of colour what the hair has gained. The most enthusiastic photographer has often felt his failure here, and has here acknowledged, that the aid of art, in colouring, is pre-eminently needed. Again it is a principle of art that the most important part of a picture should be best done, that in a portrait other parts should be so subordinated as to give due prominence to the head: and herein it is true to nature. It is on the faces of those around us we look, whether we speak or listen; it is there we look for the varying expression and developement of character, and it would speak little for any of whom, in their absence we remembered more of their dress than face. Photography, however, in its most perfect forms knows no such discrimination. Every button, fold, and flounce, is distinctly portrayed; the varying texture of silk or satin, velvet or cloth, is rendered with surprising accuracy; whilst the head, if not certainly worse done than the rest, is certainly worse in proportion, so that it appears no more important than, if not really subordinate to, the other parts of the picture. A painting of this description once under criticism, received its due meed of praise; the several parts were separately commended, the position, the draperies, &c., after which the critic exclaimed: 'Why, bless me, here's a head too!'"

The book is illustrated by a useful coloured diagram, exhibiting the relations of the primary, secondary, and tertiary colours.

Foreign Correspondence.

Paris, March 10, 1859.

We are just now very much interested in "bottled" light, and M. Nièpce de Saint Victor, in order to assure those who wish to repeat his experiments, has given a more detailed account of his method of operating, in order to enable them to obtain success. To prepare the solarised paper he proceeds as follows:—Take a piece of white card-board and immerse it for a sufficient length of time in a solution of tartaric acid, or of nitrate of uranium; tartaric acid succeeds the best. Expose the cardboard to the direct rays of the sun for four or five hours in summer, until it is saturated with light; this can be ascertained by dropping a little nitrate of silver upon it, which instantly blackens the card where it comes in contact with it. Then take the cardboard, roll it up, and place it in a tin box, and solder it so as to hermetically seal it. The card will now retain its solarising properties for an indefinite time.

When it is desired to exhibit the effects of stored-up light, some positive paper should be prepared with ammonio-nitrate of silver, which is more sensitive than the chloride. When the sealed tube is opened at the time of operating, a little water must be injected, for the purpose of damping the cardboard; but no water must be left in the tube, which must then be re-covered as completely as possible, and warmed in the flame of a spirit lamp until it has attained a temperature greater than the hand can bear, which is from 140 to 160 degrees Fahrenheit; it is then opened, and immediately applied to the negative (which is taken on thin paper), in contact with the sensitised ammonio-chloride paper.

Cardboard, impregnated with nitrate of uranium, requires only an hour's solarisation; but it loses much more rapidly the luminous action it acquires.

M. l'Abbé Despratz, to whom photographers are so much in-

debted for a rational mode of working dry collodion, has recently published some further remarks on the preparation of gun-cotton and collodion, in continuation of those he gave to the world about a year ago. He is of opinion, that gun-cotton properly made and well-kept, may be preserved for an indefinite time without undergoing any alteration. To secure this result, much depends upon very perfect washing, and upon keeping the gun-cotton enclosed within several envelopes of bibulous paper, with free access of air. He disputes the English notion of the effect of preparing gun-cotton with acids at high temperatures. He has found, that in winter as well as in summer, the chemical combination of the sulphuric acid and nitrate of potash always developes the same given temperature, which is sufficient to act effectually upon the cotton. It is important in the preparation of the gun-cotton that the mixture of acid and salt should be of a syrupy consistence; there is then no fear of an excess of nitrate of potash. The cotton must be immersed immediately the mixture of acid and salt is effected, before the sulphate of potash formed has had time to thicken the mixture. There is still another and a more important reason for proceeding promptly in immersing the cotton, which is, that its transformation into pyroxyline, goes on only during the liberation of the nascent nitric acid given out by the decomposition of the nitrate of potash. Now the elimination of this acid, which is manifested by much violence upon the first contact of the sulphuric acid with the nitrate of potash, gradually slackens; it is most effective during the first ten minutes, and this space of time is necessary to produce a complete transformation. It is always best to operate with small quantities of cotton: fifty or sixty grains is a very suitable quantity.

M. Despratz is of opinion, that the quantity of gun-cotton required to make a given quantity of collodion, need not be rigourously weighed. He proceeds in the following manner—Into 100 *grammes* of good, but non-rectified ether, he puts three or more *grammes* of gun-cotton; at the expiration of an hour, the gun-cotton, after being moved about with a glass rod, falls to the bottom of the bottle, without being really dissolved. Now add to the mixture a few *grammes* of rectified alcohol (not absolute). The cotton soon becomes dissolved; more alcohol may be added if the solution is not complete—but it must not exceed in weight one-fifth, or one-sixth, of the ether employed. If this quantity is exceeded, the strength of the alcohol must be greater. After allowing the mixture to rest for twelve hours, the upper portion is carefully decanted from the cotton that remains undissolved. The collodion thus prepared will most probably be found too thick; it must, in that case, be diluted with ether—but no alcohol, until the desired consistency is attained. It must not be forgotten, however, that collodion becomes thinner after being kept a few days than it is at first. A thin collodion is the best to work with, under all circumstances. Collodion that becomes milky, shows that it has been prepared with bad ether, or with alcohol of low strength. After all that has been said about iodising collodion, the Abbé thinks that perfection may be attained by simply employing iodide of potassium. He prepares his iodising solution as follows:—Put ten *grammes* of alcohol into a bottle, and saturate it with equal quantities of iodide of potassium and iodide of cadmium, both quite dry, and finely pulverised. At the expiration of a few hours, the solution will be effected, and the proof of complete saturation will be found in some of the iodides remaining undissolved at the bottom of the bottle. This mixture of iodides and alcohol may be made at the same time as the collodion is prepared, so that they may both be ready together. Into the decanted collodion, put, say ten drops of the iodised alcohol, which, of course, will not be sufficient, but will serve for experiment. Take a slip of glass, carefully cleaned, and cover it with the iodised collodion, and then immerse it for one or two minutes in the nitrate of silver bath; upon withdrawing it, the colour of the collodion film will indicate how near the proper iodising is attained. Viewed by reflected light, the colour of the film ought to be *blueish opal;* if it is merely *blue*, it shows that the collodion is not sufficiently iodised—if *white*, that it is too much so. By carefully adding fresh iodising solution to the collodion, and testing as before, the exact degree will be arrived at, and a picture may now be taken upon the collodion in the camera. This proof will be worth nothing: it may be covered with transparent and opaque spots; but the black portions of the picture will show if the proper degree of iodising has been attained. These spots in the collodion film are evidently due to insoluble portions held in suspension, which cannot be effectually removed by filtration. The insoluble particles must be allowed to deposit themselves gradually: and much time is required for that result; and the colour of the collodion, which gradually changes, affords a very good test as to when this deposit is complete. At first milky, the iodised collodion becomes gradually of a pale yellow; this yellow colour gradually becomes deeper, until at length it is that of olive oil. This is effected in about four-and-twenty hours. With some collodions, perfect transparency is not attained under four, or even eight days; the collodion carefully decanted, may now be used with confidence. Besides the deposits due to undissolved gun-cotton, and to the impurities of the iodides, there is another which sometimes appears, of a white, starchy appearance. This deposit, which must not be removed, is merely iodide of potassium, precipitated from its alcoholic solution by ether. After decantation, it must be re-dissolved by just sufficient alcohol, and then added to the iodised collodion. This deposit usually takes place when the ether is too highly rectified: such an ether should never be employed, as it gives negatives, deficient in harmony, from the *blacks* of the picture being too dense, while the half-tones are scarcely brought out.

The Abbé next proceeds to examine the constitution of the collodion film on the glass plate. He finds, that under the most favourable conditions, this film is not completely uniform and homogeneous, but really composed of two distinct layers, one adherent to the glass, the other superimposed upon it. The first in only pyroxyline—that is, normal collodion, with very little iodide; while the second is composed almost entirely of iodide and very little pyroxyline. There is, therefore, a mechanical separation of the constituent principle of the collodion, due to the rapid evaporation of the alcohol and ether from a large surface. An effect is in this way produced, similar to that which occurs in the drying of paper which has been sized. M. Payen has shown, that the size introduced uniformly into the substance of the paper, when dried in the air, is found on each surface, but not in the interior of the paper; and, for a perfect sizing of the paper, a combination of favourable circumstances is required, in which air, heat, and moisture, play the principal part. The iodides in the collodion are brought to the surface of the layer, opposite to the glass plate, in the same manner that the size introduced into the paper finds its way to the surface; and as paper is only really well-sized in proportion as the size is at the surface, so collodion will only be well prepared in proportion as its texture permits of the free motion of the iodides, so that they may reach the surface of the film in contact with the air, and permit of the prompt action of the sensitising and developing agents. Collodion prepared with highly rectified alcohol and ether are subject to a degree of permeability, and should therefore be avoided. J. P.

Correspondence.

ALKALINE CHLORIDE OF GOLD TONING.

To the EDITOR.

SIR,—I perceive that a little difference of opinion exists amongst some of your readers, as to the amount of over-printing which is required in the alkaline chloride of gold toning process. May I suggest that the albumenised papers experimented with, were not probably of one quality. Much appears to depend upon the selection of a suitable paper in this process, and if the wrong kind be chosen, such evils as a disappearance of the purple tints, loss of half-tone, &c., on immersion in the hyposulphite, may be anticipated. A paper has lately been made by Mr. Evans, of Nash Mills, Hemel, Hampstead, which takes the gold with unusual facility, and if he can manufacture it of uniform quality, of which I cannot certify at present, it will be a great boon to photographers. I have seen no advertisements of this paper, but it was recommended to me by an artist of great experience, and since then I have received a sample from the proprietor. Thinking that the advantage is with the consumer equally as much as on the contrary side, I do not hesitate to speak favourably of the paper as far as this single sample is concerned, being at the same time fully aware of the difficulty of producing uniformity.

Whilst upon this subject, I may notice in passing that the sketch which you have given of the gradual introduction of this process, is not quite accurate in some minor particulars. The real state of the case I believe to be as represented in the communication to the Society some two months since.

A friend of mine has lately tried Mr. Maxwell Lyte's process, in which phosphate of soda is used, and, as he informs me, with great success. On the whole the results were superior to those which he obtained with the alkaline chloride bath. The quality of the negative has much to do

with that of the print, and with negatives such as he then used, it appeared to him that he secured greater sharpness and brilliancy, by printing very deeply, and afterwards clearing up the lights by means of the last mentioned solution.—Yours, &c.

King's College, March 3, 1859. F. HARDWICH.

"CLEANLINESS IS NEXT TO GODLINESS."—*Old Proverb.*

To the Editor.

Sir,—A short time ago a lady said to her friend, who was paying a morning call, "And do you know, my dear, Arthur has caught that nasty epidemic they call photography?" "Indeed, I am sorry to hear it," was the reply, "has he it very severely?" "Yes, that he has; I fear he will be badly marked."

Now, Mr. Editor, this introduces a matter we ought carefully to consider. So long as a photographer only marks himself, his own clothes, and his own carpets, he is simply a domestic grievance: when he enlarges the sphere of his labours, and visits his friends, marking their clothes, their tables, and their carpets, he becomes a bore: but when he turns out into the world on his photographic rambles, and takes rooms at hotels, leaving behind him traces of his progress, on the floors and tables, he becomes a public nuisance, and ought to be put down. In the good old times of "waxed-paper" we used to travel about with camera and legs, taken by unsuspecting landlords for railway surveyors, telegraphic agents, or some such beings: after dinner we used to call for the hostler to bring a large jug of rain water and a stable bucket, and spreading a newspaper or two on the table, unpack our chemicals, and develope our pictures; and I never recollect a single instance in which I left a stain on table or floor. But some photographers are, either more careless or more unfortunate, so that now, hotel keepers, if they see your legs and camera, either say they have no rooms at liberty, or put you in some miserable place, where you see the sad traces of some previous professor of the "black art." Some time ago, I was in company with my friend, the discoverer of the "great gin and water process."* The train dropped us at a station in the north, near a celebrated abbey. My camera and stand were packed up to look as much like fishing tackle as possible, but my friend's camera and legs were not disguised. The porter took our luggage to the hotel, where we encountered a very polite waiter at the door. "Can we have good rooms?" said I. The waiter gave a withering glance at the legs and camera, and said he must call the landlord. Oh! for a fairy's wand, to transform our apparatus into something else, even into the stock-in-trade of a travelling tinker; but there was no such luck—we must face it out. Well, the landlord came; looked at the legs and camera, and then at us, and said—"You must excuse me, gentlemen, but really I have suffered so much from them sort of things. If you have rooms, you must promise me faithfully not to make a mess." My friend was so much ashamed, that I really think he would have gone back by the next train, but I said, "Oh, you may trust us, we are dry photographers." Whether he understood my meaning, or whether he had visions of long bills for bottled stout and pale ale, I cannot say, but he at once admitted us, and we had the best rooms in the house.

During our stay, we listened to his photographic grievances, of which he had a long string; how his furniture had been spoiled, and his table covers and carpets spotted and stained all sorts of colours. Two gentlemen from London had been there, on a photographic expedition; when they left he went into their sitting room and found all right, apparently: the next day, sundry large stains made their appearance on the carpet, which bye and bye turned into sundry large holes. We strongly advised him, before we left, to look very shy at all photographers, unless they were *dry* ones.

Now, Mr. Editor, I think you will agree with me, that there is no occasion for all these messes: every photographer ought to learn to take pictures without either staining fingers or any thing else, and until he can do so ought not to be admitted into a respectable hotel. What do you think of a grand central photographic hall, where all photographers must take their degree before they can practice? or if that plan would be too costly, that Justices of the Peace be empowered to grant licenses, on the applicants proving their fitness, by bringing all necessary materials to the Justice's house, converting his library into a dark room, and taking at least six good collodion pictures without making a spot; the police being instructed to put in jail any photographer travelling without a licence.

I merely give you these as suggestions; but *something* must be done, or we shall have notices put up at the entrance of every village—

ALL VAGRANTS OR PHOTOGRAPHERS

ENTERING THIS VILLAGE, WILL BE

PROSECUTED WITH THE UTMOST RIGOUR OF THE LAW.

Yours, &c.

Manchester, March 10, 1859. JOB TROTTER.

* I may just add, that I am not *the friend* he alluded to, who complained of the solution not keeping.

PRINTING DIFFICULTIES.

To the Editor.

Sir,—Would you kindly tell me in your very valuable Journal, what effect is produced by using an old nitrate bath for floating paper on; of course there must be a very large amount of nitrates of soda or baryta, or whatever the paper is salted with, which will increase as water and nitrate of silver are added to make up for diminution. This is a point which I am sure your able pen would clear up; and as I am convinced some failures have arisen from this cause, you would receive the thanks of many photographers, including your very obliged correspondent.

I am, yours, &c. T. C. D.

[By an *old* nitrate of silver bath, we presume you do not mean one that has been used for negatives, but only that has been in long use for exciting printing papers. If the former, it contains alcohol and also iodide of silver, and these would be detrimental to a great degree. In this case you had better throw down all the silver in the shape of a *carbonate*, by adding excess of solution of sesqui-carbonate of soda (in *distilled* water), and re-dissolving the precipitate (after washing) in dilute nitric acid.

The same course of proceeding may be adopted, if necessary, even if the bath be only such as has got much out of order, by floating papers thereon; but in all probability your troubles arise not from preponderance of nitrate of potash, &c., so much as from deficiency of nitrate of silver. Remember, that each sheet of paper floated upon a bath *abstracts* nearly *double* the quantity of the silver salt indicated by the quantity of liquid removed; hence the constant reduction in strength of the silver bath, until at last it becomes too weak to give presentable pictures with any amount of time for contact with the papers. The fact of this reduction in strength has been demonstrated beyond the possibility of doubt, by Messrs. Davanne and Girard, even did not our own practice prove the same.

Organic impurities are readily removed, by a few drops of citric acid, as suggested by Mr. Eliot, correcting the acidity engendered by subsequent addition of a few drops of carbonate of soda solution.

You should ascertain by direct experiment, the quantity of nitrate of silver now in the bath by precipitation with a chloride from a given quantity, drying and weighing the chloride formed.—Ed.]

A DRY SUBJECT.

To the Editor.

Sir,—I hope you will not consider the following question irrevelant.

In taking pictures by J. W.'s gin and water process, will not the best and most appropriate diaphragm be the "bottle?"—Yours, &c.

Manchester, March 2, 1859. PHOTO.

PRINTING DIFFICULTIES, &c.

To the Editor.

Sir,—Would you kindly tell me in your very instructive and able Journal what is the best paper to use—1st, For simple salting, and 2nd, For albumenising. ———'s albumenised is in my hands extremely unsatisfactory; the picture after fixing and toning is weak and wanting in depth and brilliancy, although I use an eighty grain sensitising bath of nitrate of silver. It cannot be in manipulation, as I succeed admirably with paper I prepare myself, or with Spencer's albumenised, which, with an eighty grain sensitiser, is magnificent, but somewhat expensive.

Will you also tell me where I could get a good detailed account of the meta-gelatine process, which Mr. Heisch so much praises in your last impression.

Many thanks for your past favours to me and my friends; you do not know how eagerly we look forward to the publication of your Journal, it contains so many new "dodges," and is a source of enlightenment to the whole photographic world.—Yours, &c. JABEZ JARBER.

[We have sometimes found the same fault of which you complain with the paper named by you, but chiefly when it has been only *lightly* albumenised, or when a delicate but not intense negative has been employed. You will, we think, be able to remedy the defect by allowing the sheet to remain in contact with the sensitising bath a longer time, or by using the bath still stronger. This of course applies if you happen to have a stock of the objectionable paper, if not, use some other kind.

The choice of a paper for salting and for albumenising, depends also upon the special purpose to which you desire to apply it. For portraiture, we prefer as a plain salted paper, a *thick* kind of Saxony paper (sized with starch), sold by Messrs. Knight & Son; Sanford, and other dealers, or else Messrs. Marion's, which they call *helio-velin.* For landscapes we prefer an English paper, in preference Hollingworth's thick paper, next the same maker's thin, or Harrison's paper, these two last being about equal in value, then Towgood's.

For albumenising, any of the preceding may be used, but we think the preference may be given to Harrison's, or Hollingworth's thin paper.

Canson's paper when good is very good, but the *thick* paper is what we mean.

You will find the process alluded to by Mr. Heisch in No. 76 of the *Journal of the Photographic Society.* Mr. Heath, of the firm of Murray and Heath, Piccadilly, may be able to give you the formula as originally recommended by the Rev. Mr. Cleaver.

Thanks for your good opinion.—Ed.]

CARBON PRINTING.

To the Editor.

Sir,—Having bought a ticket in the Pouncy lottery, and drawn a *blank*, I wish to know if any gentleman has succeeded in getting a *prize*. If so, would he kindly favour me with the particulars of his manipulation.

As to getting the picture out by soaking, I believe that to be impossible. I succeeded in getting something like a print, by putting the paper on a glass plate, and holding it under a tap, with a water pressure of about 20 feet, but even with that I could not get the lights clear. I think, that the next best thing to try will be a jet from the town fire engine.

If permanent prints are wanted, let me advise the general adoption of the old ammonio-nitrate process. I have a print by me printed by that process in 1847, which is now as good as ever, and as it was considered an inferior print, it received but very little washing, and that in the waste hot water from a steam engine. It is printed on old satin post writing paper, and has not been protected by a glass, but generally pinned against the wall in various places, damp and dry. Should you like to see it I will send it for your inspection.—Yours, &c.

Mansel Street, Swansea. THOS. GULLIVER.

[We can vouch for the fact that all are not quite so unfortunate as our correspondent, though we have not yet seen reason to give up silver printing.

Instead of its being sent for *our* inspection, we will beg the owner to present it to the Photographic Society, to form one item of the collection illustrative of the progress of the photographic art from its earliest date.—Ed.]

Mr. BURNETT and Mr. HANNAFORD.

To the Editor.

Sir,—In the last number of the Photographic Society's Journal, I observe a letter from Mr. Burnett in which he claims to have published the principle of the iron printing process, as practised by me, in the November 22nd number of that publication, and on reference—for I had not previously seen his remarks thereon—I find that he is quite correct in his statement.

The process however is quite original on my part. Indeed you may remember that on the 24th November, that is only two days after Mr. Burnett made his process known, I exhibited some prints at the meeting of the North London Photographic Association in your presence, and that one of the Committee had seen these specimens fully a week before. Up to that date (the 24th), I had not read Mr. Burnett's numerous papers, but from some remarks, *then made by yourself*, my attention was called thereto, and I gladly admit that I have since greatly benefitted by his interesting researches.

It is to be regretted that much of the very valuable information which Mr. Burnett has from time to time given us is so likely to be overlooked, from the fact that it is distributed among so many Journals.

I trust both Mr. Burnett and yourself will acquit me of having copied this process, and given it out as original.—Yours, &c.

Stoke Newington, Feb. 24th, 1859. MICHAEL HANNAFORD.

[We have already personally expressed to Mr. Burnett our conviction that you are free from any charge of plagiarism; and are fully impressed with the merit of his suggestions.—Ed.]

PHOTOGRAPHIC BATHS FOR TRAVELLING.

To the Editor.

Sir,—In the last number of a contemporary, is a letter from Messrs. Forrest & Co., stating that they are about to make moulds for glass baths. Perhaps a few hints from a travelling photographer may be useful.

The three landscape lenses now in most general use cover pictures of the following sizes, 12×10, 10×8, and 9×7, below or above these sizes are not so much used.

As these are the actual sizes of the picture, it is getting general with photographers to have the glass plates an inch longer each way, so as to allow a margin for the rebate of the slides, the thickening of the collodion film, and any blemishes at the edges; thus the sizes of the *plates* become 13×11, 11×9, 10×8.

Very few photograpers travel with a glass bath, partly because of the baths not fitting the above sizes, but chiefly on account of the immense weight and quantity of liquid they contain. A glass bath for plates 11×9, as now obtainable, is absurdly made $1\frac{3}{8}$ inch clear width, so as to require nearly six pints of liquid; for the stay-at-home photographer, quantity and weight are of no importance, but they are a bar to travelling purposes. Now to keep down this quantity of liquid, the baths should be made V shaped, as first brought out by the late F. Scott Archer, and it will be quite sufficient for all purposes to have them $\frac{3}{8}$ of an inch clear width at bottom, and $\frac{5}{8}$ clear width at top; thus made, a bath for plates 11×9 would require less than two pints of liquid, and would then become something manageable for travelling operators. This $\frac{5}{8}$ clear width at top is ample and more than ample for even a clumsy operator.

When the bath is inclined for use, one edge of the bath at top is lower than the other, and about half an inch in depth of bath is lost by this; the step at foot of the dipper entails a loss of another half inch, and to prevent overflow, and allow for waste of liquid in a day's excursion, another inch of depth should be allowed. Thus the inside of the bath should be two inches deeper than the longest side of the plate.

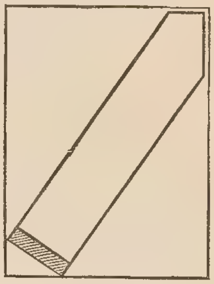
For the three sizes of plates I have mentioned, the baths would then be by *inside* measurement:—

No. 1. $11\frac{1}{2}$ wide $\times$ 15 deep, $\times$ $\frac{5}{8}$ wide at top, and $\frac{3}{8}$ wide at bottom,
No. 2. $9\frac{1}{2}$ " $\times$ 13 " $\times$ $\frac{5}{8}$ " " $\frac{3}{8}$ "
No. 3. $8\frac{1}{2}$ " $\times$ 12 " $\times$ $\frac{5}{8}$ " " $\frac{3}{8}$ "
No. 4. 5 " $\times$ $9\frac{1}{2}$ " $\times$ $\frac{5}{8}$ " " $\frac{3}{8}$ "

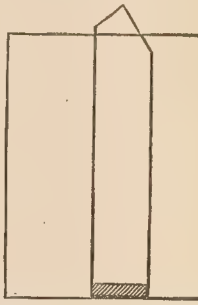
The tops to be ground level so as to be fitted with water-tight covers if required.

The dippers should be made of glass, thus:— 
with the top end so pointed as to lay cornerways in the bath with the cover on, as here shown.

AS PACKED UP.



AS IN USE.



By this means every thing packs up quite securely, and the trifle of shake is not sufficient to break either bath or dipper in travelling.

The best case for a glass bath is not wood, or metal, or cork, but gutta percha, wrapped round while hot, so as to cover the glass all over, adding a thick band round the top for the clamps to pull against. Should the bath fall down and crack, it is nearly as good as before, for there being no space between the glass and the gutta percha, the liquid cannot escape; but a glass bath simply dropped into a wooden or gutta percha one is useless if cracked, for then away goes the greater part or all of the solution.

The India rubber of the bath cover must not be vulcanised; the sulphur comes off in the bath and does much mischief.—Yours, &c.

London, March 2nd, 1859. A TRAVELLING PHOTOGRAPHER.

ANSWERS TO CORRESPONDENTS.

☞ We must remind our correspondents, that if they send their letters on *editorial* matters to Liverpool, a delay in publication or reply may and sometimes must be the consequence.

—— We have received, from an *unknown correspondent*, a beautifully executed portrait of a lady, standing, well posed, and nicely printed. It was addressed personally, and forwarded from the Photographic Society's Rooms, Coventry Street. We regret that we cannot thank our correspondent by name.

Kate R. R.—Your signature to the former communication misled us, the two last letters having been mistaken for B., so that the reply under that head *was* intended for you. Our present leader will give you the information required. In stating that the other was a mechanical mixture, we were referring to its mode of manufacture, not to its chemical composition.

James Jones—1st, Iodide of cadmium. 2nd, Iodide of ammonium.

Inquirer—Albumenised paper varies very much in quality, especially as regards its property of retaining its colour unimpaired after being sensitised. We think this is due more to the paper than to the albumen generally.

John Glover.—We have mentioned the fact, that you have no connection with your namesake to whom allusion is made in our Leader.

A Subscriber—Collodion pictures have been taken on paper by attaching the latter first (with a little gum round the edges) to a sheet of glass, and then proceeding as in the ordinary way, only pouring the collodion on the paper. To transfer collodion pictures from glass to leather, pour over the collodion alcohol, having four or five drops of nitric acid added to each ounce; then press the leather closely to expel air bubbles, and allow it to dry, when the collodion can be removed adherent to the leather. This is not from our own experience, never having practised the transferring process.

It has been *asserted*, that pictures have been taken by accident with the natural colours; but they have never *remained* in that condition after drying. M. E. Becquerel procured something of the kind upon chloride of silver, prepared in a peculiar manner, but was quite unable to fix the impression, which faded gradually, even from the effect of artificial light, by which alone they were viewed.

M. Becquerel's paper on this subject may be found in our last volume.

In-quest.—We must beg your patience till our next, as we have not room for a proper reply to you in this number.

Received.—"A. M'Nab," "J. S. Moon." Unavoidably postponed.

THE PHOTOGRAPHIC JOURNAL.

No. 91, Vol. VI.—APRIL 1, 1859.

In a letter from our Paris correspondent, dated 22nd February, which appeared at page 62 of the present volume, we learned that Mr. Wheatstone was invited to witness the experiments of M. Nièpce de St. Victor in the application of light that had been sealed up since June last, for the production of a photographic impression. On inquiring for further details of the experiments said to be so successfully performed, we find that a little water was on opening the tube first projected into it, and immediately thrown out again, the cover replaced, and the tube heated over a spirit lamp before its orifice was applied to the printed paper acting as a negative over the ordinary sheet of sensitive paper. It is stated that an impression was the result, and we have no doubt such was the fact; but there is *no evidence*, absolutely none, that the impression was due to the action of *light*.

Let us, however, look a little further: Mr. Crookes has stated that he repeated M. Nièpce de St. Victor's experiments, omitting, however, the *insolation* of the paper—rather an important omission it will be allowed—but, marvellous to relate, the results were just as marked as those of the illustrious foreigner, the impression being made as well, without the "bottled light" as with it.

In a recent number of *Cosmos*, edited by the Abbé Moigno, a translation of Mr. Crookes's account of his experiments is given, and the following droll comment appended:—

"Evidently Mr. Crookes does not correctly interpret his experiment, and wrongly (!) concludes that *in M. de St. Victor's tubes* it is not light which acts. What does this experiment in fact prove? That heat produces in *Mr. Crookes's* tubes the same effects that M. de St. Victor attributes to light—nothing more or less." Quite sufficient, we imagine, to satisfy any reasonable mind that the action has been *attributed* to light without sufficient foundation, that is, if Mr. Crookes has stated correctly his experiment—a fact of which we entertain no doubt whatever.

The projection of the water into the tube, and afterwards converting it into steam, of course at once suggests the possibility, not to say probability, of chemical action, *exclusive* of actinic force; and with a piece of printed paper only as a negative, there is no impediment to the chemical or physical action of the *vapour*, except in those parts where *the oleaginous nature of the printing ink* intercepts the passage of the aqueous particles.

It must also be borne in mind that sensitised chloride paper becomes discoloured in the dark, with a rapidity and energy directly proportioned to the heat and moisture present. The experiments of MM. Davanne and Girard leave no room for doubt on this point; and it appears to us far more logical to presume that the effect produced arises from a cause admitted to be *capable* of producing it, and which is clearly in a condition for action, than to presume a supposed *new action* of light, of which previous experience gives us no indication, in order to explain that for which existing and well-known phenomena are quite sufficient to supply the *rationale*.

If M. de St. Victor's experiments are worth anything at all, there is no reason why the impression should not be made through a *negative on glass*. There is no difficulty in producing a negative on glass as thin as a piece of card; but supposing even an impression to be made in like manner to that with the printed bill, it must also be shown that a similar proceeding will *not* make an impression without the paper has been previously "saturated with light," before we can admit the correctness of the conclusions to be drawn. Nothing short of this can be satisfactory.

No man, be he ever so learned, is infallible; and if M. Nièpce de St. Victor has made a mistake for once, there are few so well able to afford the admission of it without loss of *prestige*. We suspect, however, that the difficulty does not lie so much with M. St. Victor, as with his admirers amongst his own countrymen.

We had occasion, in our last, to notice the increasing tendency to fetter the use of certain photographic processes and apparatus by restrictive patents—a course which photographers, as a body, should set themselves seriously to keep within due and legitimate bounds. It should be the business of every photographer to assist in defeating all attempts to obtain exclusive privileges in the use of those advantages which have been unreservedly published for the general good. As if to point the moral more particularly, we find our brethren on the other side of the channel just now involved in as pretty a squabble upon a matter of this kind as can well be desired.

So far as we can gather them, the facts appear to be as follow:—

It is but recently that M. Marion exhibited at the meeting of the French Photographic Society a box for the preservation of sensitised paper (a description of which we gave in our last), containing, as a desiccating agent, chloride of calcium. There was no secret made about the matter; in fact, it was alleged to have been produced in consequence of the very practical researches into the *cause* of deterioration by MM. Davanne and Girard. But we remember that, some months previously, M. Cognacq, of Rochelle, was about to exhibit and explain, at the then meeting of the same body, a box, possessing, or alleged to possess, the identical qualification—on his understanding, however, that his so doing would prevent his obtaining a patent, he *abstained* from making the proposed communication. It appears, subsequently, that some sort of protection was obtained by M. Cognacq, but it is not even pretended that MM. Davanne and Girard had any knowledge of M. Cognacq's method of operating; these gentlemen are however admitted to have been independent discoverers of the principle, and they declare that they did communicate it to M. Marion.

M. Marion is accused of having surreptitiously obtained his information of the contents of M. Coguacq's box, the former having had one of them in his possession for about a fortnight. Now comes the extraordinary part of the affair. M. Marion secures, or attempts to secure, *a patent* for his box, identical in principle with that of M. Cognacq's; but not on account of being the discoverer of *the principle*—that is admitted by him to belong to the eminent chemists previously named—so the patent can only apply to the form of the apparatus, if it applies to any thing.

We are not aware of the bearings of the patent laws in France, but it certainly appears as if they were in no more satisfactory condition than our own.

We are not going to enter into this squabble, or pronounce any opinion upon the merits of the contending parties ; but as it affects photographers generally, one thing is abundantly clear—either the public or M. Cognacq must be suffering an injury.

The principle of action being known, the arrangements necessary are so obvious that they cannot fail to occur to any one interested in the matter: witness, for instance, the facts mentioned in a letter from Mr. Church, published in the present number, which will be found amongst our correspondence.

We give, in another column, particulars of a discovery likely to be of service to photography in connection with collodion. It appears that Dr. Schweitzer, of Zurich, has discovered new solvents, not only for cotton but for vegetable substances, and also for silks. These seem worthy of attention and careful examination, with a view to their application either for an economical collodion or for forming a transparent and structureless medium on which the collodion film can be supported instead of glass. The details will be found in a paper by M. Léon Krafft.

We have recently been experimenting rather extensively upon the developement of collodionised plates, either dry or preserved in a sensitive condition by means of honey syrup, and the results have been decidedly satisfactory, so far as Dr. Hill Norris's gelatinised plates or those prepared with honey were concerned.

We were led into the investigation from having, in the earlier part of last February, exposed a few of Dr. Norris's plates under unfavourable circumstances in the Scottish Highlands. In consequence of the temperature being low and the sky overcast, with a dark subject we were induced to make use of the acetate of iron as a preliminary developing agent, following Mr. Hardwich's formula, which directs a considerable quantity of free acetic acid. We had previously employed this agent successfully with syruped plates, but had never before applied it to dry ones. The only difficulty we experienced was in making the solution flow readily over the plate, which had first been moistened with distilled water, the difficulty arising from the volatile nature of the acetic acid preventing the water and developing solution at once combining readily.

Of course we need scarcely remark, that in developing dry plates it is a *sine qua non* that nitrate of silver should be present, and consequently the addition of some free acid to the iron solution is also a necessity to obviate fogging, which would otherwise certainly occur.

The difficulty of making the two solutions combine readily upon the plate demands a considerable amount of manual dexterity in order to avoid stains, and the sudden way in which the image flashes out in parts, leaves the operator under the impression, at the first appearance of these patches, that the negative is hopelessly spoilt. A little patience, however, sets that matter to rights; but then comes another trouble—the developer must be pretty speedily washed off, and it is just as awkward to make the water take kindly to the solution, as it was previously to make it agree with the water.

Another objection we also found to exist to the image thus obtained, on dry plates especially ; its gradation of vigour was not at all under control — it would come just to one degree of intensity, which could neither be surpassed or fallen short of. It is true that by clearing the plate of the iodide of silver, and then using pyrogallic acid solution, with a little nitrate of silver, the image was capable of intensification to almost any requisite extent — but the principal defect consisted as usual in the condition of the half-tones. If the exposure had been accurately timed, all was just what one could desire; but if it were a little over or under exposed, there was no possibility of assisting the result by increased or retarded developement.

We found there were certain advantages, however, in using an iron developing agent, that are by no means lightly to be discarded — amongst them, that about one-half the exposure required with a pyrogallic developer was sufficient to impress all the details of the subject. We therefore set to work with a will to endeavour to remove the various objections, and succeeded to our entire satisfaction. We have much pleasure in laying the result before our readers, and have little doubt that many of them will find it a highly convenient method of operating.

The plate having been removed from the dark slide, is to be placed, face upwards, in a horizontal dish, and sufficient *distilled water* to entirely moisten the whole surface gently poured over it and immediately off again. The plate should then be taken up and attached by the back to a pneumatic holder. The developing solution is then poured on in the usual way, and kept in motion until the image is satisfactory. To prepare the developing solution, take protosulphate of iron one drachm, citric acid four grains, put together in a mortar and reduce to a fine powder, then add four ounces of *distilled water*, and stir until dissolved. This will be found to flow over the plate as readily as simple water, and is easily washed away when done with. Just before using it, a few drops of a pure solution of nitrate of silver must be added to that portion intended to cover the plate; but it should be simple nitrate of silver, containing no iodide, chloride, &c., consequently, some from the exciting bath is not applicable for the purpose.

The reason for this is, that as soon as a portion of the silver becomes reduced by the iron, the remainder is lowered in strength, consequently a part of the iodide previously held in solution is thrown down in the form of a fine powder, and not only is the solution rendered muddy, but the film is soon covered by it, and thus appears minutely speckled all over.

In preparing the developing solution as above indicated, the quantity of citric acid is not a constant quantity, but should be varied according to the temperature ; the criterion being to use as little as possible, but not to use so little that the mixture of the solution with that of the nitrate of silver becomes embrowned under from three to five minutes' time. If on trial it is found to do so, a little more citric acid must be added, until it will retain its limpid appearance for the space of time specified.

This developer, unlike those of the iron preparations generally, *gradually* brings out the image, enabling the operator to arrest the action at any stage he may think proper, and if a little honey syrup be added while developing, a very intense deposit may be obtained without the subsequent use of gallic or pyrogallic acid, as the organic matter required to produce the density desired is supplied by the syrup. The plate may afterwards be cleared and the developement carried still further if thought desirable.

If syrup has been added, hyposulphite of soda should be the fixing agent, cyanide of potassium reducing the intensity so much as to make redevelopement necessary, which is not the case when the hyposulphite of soda has been employed instead.

In working with syruped plates, precisely the same mode of operating may be adopted, only, of course, it becomes unnecessary to add any more syrup to the developing solution, and the hyposulphite only should be used for fixing.

The same distilled water may be used for moistening the surfaces of several plates that are intended to be developed consecutively.

We have not tried this method of operating with collodio-albumen plates, only with those kinds mentioned, but we see no reason why it should not be equally applicable with all dry plates, however prepared.

We have only one more remark to make in connection with this mode of proceeding; if the solution on the plates turns brown before the developement is complete, it must be poured off and replaced by some fresh.

Although we have made use of many words to describe the preceding, it is exceedingly simple; but we like it so well ourself that we are desirous our friends should not be liable to failure from want of any of the minutiæ of details. We have no doubt many will try it, and we shall be glad to be favoured with the results of their experience.

We were not a little startled the other day at reading an advertisement which appeared in one of the daily penny newspapers, to the effect that some Young Ladies were wanted as sitters for stereoscopic subjects, with an intimation where to apply. What inducement is held out to applicants did not appear. We certainly found ourself speculating upon the point as to whether the advertiser is most entitled to admiration for his *simplicity or his cool assurance.* That any young Ladies will be attracted by the impertinent intimation we certainly have no fear; but we cannot forbear protesting against a proceeding that is likely to bring ridicule if not censure upon our professional brethren generally, if such an advertisement be continued.

THE FOTHERGILL PROCESS.

By Alfred Keene.

As the time has now arrived when photographers wipe the cobwebs from their apparatus, look up their "Processes," and prepare in earnest for action, a general detail of the "Fothergill Process," with such additions as the experience of others, and a series of elaborate experiments undertaken by myself, indicate as desirable, will doubtless prove acceptable to your readers, both from the justly obtained extreme popularity of the process and its preeminence *even over the wet,* for taking those charming bits of landscapes (only to be obtained at this season, before nature again clothes herself with rich green foliage), requiring the retaining of distant objects until near ones are well out, and which it performs in a manner *peculiar* to *itself.*

The Glass Plates.

These should be thoroughly clean, equally so as for the wet process. Glass that has been used or obtained from the sheets ordinarily sent out, should invariably be placed, first in a strong solution of soda, and then in *strong* diluted nitric acid, thoroughly washed, wiped dry, and finished with "plate-cleaning liquid;" but that of Messrs. Forrest & Co., besides being excellent in quality, I find to possess the *great advantage* of freedom from extraneous impurities, and only to require well washing, drying, and finishing with "plate-cleaning liquid"—a mixture of *very fine* tripoli and spirit answers well for this purpose, a little to be poured on the centre of the plate, and rubbed with a pad made of chamois leather, until it "bites" equally on every part, and the surface has become quite dry; this need not occupy more than about half a minute, when on wiping off the dust, and applying the "breathing" test, the plate will be found beautifully clean.

The Bath.

This should be made with prepared nitrate of silver—*pure nitrate entirely deprived of free nitric acid*—thirty-five grains to the ounce of water, saturated with iodide of silver in the usual way, with one drop of glacial acetic acid (as the silver is generally slightly alkaline), added to every fifteen or twenty ounces; this strength to be kept up by the addition of prepared nitrate of silver from time to time, allowing about two grains for each stereoscopic sized plate sensitised.

Preparing the Plates.

Carefully remove dust from the surface of the glass, coat with collodion, and when *well set,* immerse it in the bath; allow it to remain a few seconds after all greasiness disappears; take it out and place on a levelling stand, or better still, on thick pieces of glass (smaller in breadth than the width of the plate), on a suspended shelf; allow it to remain for about half a minute,* but in summer from ten to fifteen seconds only.

Wash the Plates,

or more properly speaking, dilute the nitrate of silver on the surface as follows, viz., for a stereoscopic plate take four drachms of distilled water—a larger size will require a proportionate extra quantity—pour this *lightly* on at one corner, at the same time gently inclining the plate that it may flow *all over,* without the loss of any portion; reverse the motion that it may flow back again, and also from side to side, and continue until all greasiness disappears, taking care that it gets well up to the edges, *that the silver solution may be evenly diluted on every part;* this operation requiring, at this season, from half a minute to a minute according to temperature; in summer about fifteen seconds; then empty off the water, and place the plate as directed before washing it, but not on the same plate holder or piece of glass (fingers should be free from the bath solution when handling it); and

Coat with Prepared Albumen,

composed of white of fresh eggs and distilled water, of each ten ounces, strong liquor of ammonia eighty minims, agitate till the whole has become a perfect froth. *Filter through sponge always prior to use.* Pour on as much of this solution as will well coat the plate, at the same time giving sufficient inclination to make a little run over the opposite end, pass the remainder backwards and forwards that it may cover every part *well up to the edges,* then add a little distilled water, and pass this a few times from side to side, &c., empty it off, drain for a few seconds, and

Wash Thoroughly

as follows:—place it in a dish *larger* than the plate, containing distilled or filtered rain water, to cover it to the depth of a quarter or half an inch, agitate well for a few seconds, then leave it while a second plate is coated and placed in the bath. When this is done, again well agitate the dish till the plate is thoroughly washed; repeat with a second or even third quantity of water; if only a second is used, flush a portion well over it so as thoroughly to remove the excess of albumen. Hold it for a few seconds to drain (the hands must be quite free from albumen or silver). Place on one corner, on blotting paper *upon glass,* till "surface" dry, finally "film" dry, in any convenient manner at a temperature of 100° to 120° Fah.—the plate may for this purpose be *placed* for five or ten minutes on bricks that have been put into an oven till sufficiently hot. For keeping the plates uninjured, *tin boxes* are decidedly best, but next to tin, mahogany is least objectionable.

The Operating Room.

At this season of the year, when temperature is low and the atmosphere frequently surcharged with moisture, precautions are necessary with regard to it, not needed in summer when the reverse atmospheric condition is the case; and I am quite satisfied that many excellently-prepared plates have been spoiled for want of a knowledge of this fact. The temperature should not be under 54° Fah., from that to 60° is best; or not only is a portion of iodide liable to be deposited from the collodion, but all parts of the operation proceed much more slowly. The room should also be free from dust and *dry.* My recent experiments have given me indisputable evidence of the necessity of a dry room for the purpose of "surface" drying the prepared plates, they having shown that if the film be allowed to remain a long time moist *wavy marks appear on developing exactly similar to those occasioned by imperfect washing.* New wood of any description, more particularly *deal,* is to be *avoided* for either draining plates upon or resting them against: the injurious effect from this cause is easily shown, by dropping upon a moist prepared plate water that has stood for some time on a piece of deal—a nonsensitive patch will result wherever it has come in contact. *Glass is best for this purpose and unexceptionable;* damaged pieces laid upon an ordinary shelf, or a long strip, which can be obtained from any glazier for a few pence, answers well, providing they are sufficiently wide to prevent either water draining over the edge, or blotting paper coming in contact with wood. I have lately had my operating room arranged as follows:—For draining the plates upon I have made use of a glazed frame, with moveable cross bars of wood, framed with glass *rather wider* than the cross bar, and made to adhere by means of liquid glue, placed at convenient distances for leaning them against; underneath this is a metal box, four feet by eighteen inches and six inches deep, the bottom made of galvanized iron, the top of zinc, one end rests on a modified gas stove, to which a pipe is adapted for carrying heat along underneath the centre, and continued on into the chimney, by which all sulphurous or other fumes produced by the combustion of the gas are effectually got rid of: the other end is supported by two legs; on the upper part of this end, near the edge, a pipe is inserted for condensing surplus steam should it be formed, and near to it there is a small orifice that will admit of a funnel for supplying it with water, with which I keep it about half or three-fourths full, a cork being inserted in the orifice to prevent steam escaping.

When required the gas stove is lighted, and in about ten or fifteen minutes the room is at a good operating temperature, the

* Recommended by Mr. Glover in *The Photographic Journal,* March 1st.

diffused heat from the surface of the metal box or boiler quickly "surface dries" the plates placed on the glass just above it, they are then placed for a few minutes on the top of the boiler, which effectually "*film* dries" them; this method I find to answer exceedingly well. The heat is entirely under control, and can be regulated with exactness; it is at all times ready for use and free from dust.

The Exposure, Developing, and Fixing have been so frequently and fully described, and at present there is so little new to communicate, I feel it will be only unnecessarily lengthening an already lengthy communication to touch upon them.

In conclusion, I beg, in a friendly spirit, to make a few remarks upon Mr. Glover's "Hints on the Fothergill Process," published in your Journal, March 1st, which I read with much pleasure; they evidence no small amount of painstaking and much ingenuity.

The allowing a plate to remain on taking it out of the bath before applying the water I find to answer the purpose exceedingly well, but suggest that half the time mentioned will be sufficient in summer, or the film will most probably begin to dry and so offer a greater resistance than even when immediately taken out of the bath. The manner of applying albumen I also consider good and to possess advantages, *though not those mentioned* by Mr. Glover; for if silver solution be left sufficiently concentrated on any part of the plate to form a coagulum, *a film of albumino-nitrate of silver* will adhere *firmly* to the surface, on applying albumen *however quickly or in whatever quantity it may be made to flow over:* it is true a large portion of coagulum would float and carry off, but this, if allowed to remain, would not do further mischief; this being the case, it is evident it will not do to trust to anything but the *even* dilution beyond coagulation point of the silver solution for prevention of wavy markings arising from formation of this film.

The plan recommended for washing plates after the albumen has been applied is exceedingly ingenious, and I have no doubt will be found always thoroughly to answer the purpose, but I, nevertheless, still prefer my old plan of using a dish, which is much more simple and equally effectual. There is one point on which Mr. Glover is in error, which I beg to correct, viz., his supposing the theory to have been propounded that *much washing* of albumenised plates causes *loss* of sensitiveness; he will find in my pamphlet I direct the plate at this part of the process to be *well washed*, and in my communications I have laid great stress upon the necessity of attending to this in order *to prevent* loss of sensitiveness.

Though not entirely agreeing with all Mr. Glover's "Hints," I nevertheless consider them valuable, and, as he will perceive, have taken advantage of a portion in this communication.

ON COATING GLASS PLATES FOR COLLODION NEGATIVES OR POSITIVES, WITH A FILM OF ALBUMEN.

By Alexander M'Nab.

I have tried the preparation of plates (as recommended before the Manchester Photographic Society), with gelatine four grains to the ounce of distilled water, and the proper proportion of absolute alcohol. This preparation when completed is liquid and clear; the glasses, when coated and dried before a brisk fire, show little or no sign of anything having been applied to them.

At first I was so taken with this process, that I had serious thoughts of abandoning the albumen (which I had previously been in the habit of using) altogether, and substituting gelatine. After a few trials, however, I found that in *my* hands it was not to be compared with the albumen. The *first* plates developed clean, but soon began to exhibit symptoms of fogging, showing small pimples in the film, as if working with an alkaline bath. I found also that the plates after being prepared for two days, when put in use, parted with the collodion more readily than glasses cleaned in the usual way; this would be a serious drawback to its general adoption for the wet process.

It is far different with plates coated with albumen: these once properly prepared will keep for an indefinite period, the film *never* gives way, and there is no danger of being troubled with dirty glasses.

I do not use *patent plate* for either positive or negative pictures, that which is known as flatted-picture-sheet glass answering the purpose equally well. This suggestion was made to me by Mr. Church, and the experience of twelve months fully verifies its truth.

After numerous experiments, the following I have found to be the best way of proceeding.

Take four fresh laid eggs, beat up the *whites* to a froth, add sixteen ounces (by measure) of distilled water, a piece of camphor about the size of two peas, twenty drops of glacial acetic acid, filter when settled, and it is ready for use.

When the plates have been partially cleaned with a preparation of water saturated with common salt, and containing a portion of rotten stone, and wiped dry with clean *steam loom cotton cloth*, kept for the purpose (which I find better than linen diaper), take a large camel hair brush, mounted with tin, dip it in the albumen, and brush over the plate; this is done to allow the albumen to flow freely, which is now poured upon the plate (by this method the strength is always known). The superfluous solution is run back into a bottle through a filter; when drained sufficiently it is set on end upon blotting paper for a short time, and afterwards held before a brisk fire to dry. It is then ready for use for either negatives or positives by the wet process.

When thus prepared you will not be troubled with dirty plates, and they can even be redeveloped or whitened with bichloride of mercury, without fear of the film giving way. This is one of the severest tests which can be applied to a collodion plate.

The question may be asked, how long will they keep good after being thus prepared? I have heard it asserted indefinitely; some experiments may settle the question.

Mr. Young, of Helensburgh, having prepared a large number of plates for use at a future time, found that by keeping they became mouldy, and gave foggy results. From a series of experiments since instituted, there has been found a remedy for this evil. In order to test it fully, glasses cleaned the usual way were tried, first, to ascertain that the bath was in good working order; this point being established, a plate prepared more than twelve months was next tried, when the result proved corroborative of Mr. Young's assertion, viz., that it would fog. Being satisfied that this was the case, the plate was taken, and a solution poured upon it of—

Protosulphate of iron	1 ounce.
Distilled water	12 ounces.

(As suggested by Mr. Shadbolt).

This was done in order to coagulate the albumen; then after washing off the iron and drying the plate, the result proved most satisfactory, although the plate was mouldy previously to its being treated with the protosulphate of iron.

Here, then, from an experiment, the results of which have been uniformly the same, is seen the advantage of having always on hand a stock of prepared plates, upon the working qualites of which you can rely with positive certainty, besides the great saving, not only in material, but in time and labour, a boy being able to prepare a large number in a very short time.

The foregoing has been written in the hope that it will tend to remove some of the difficulties under which many of your readers labour, and should the practice prove as satisfactory to them as it has to the writer, he will feel a pleasure in having been of some service.

NEW SOLVENTS FOR COTTON AND SILK.

By Leon Krafft.

For some time past, it has been known to the scientific world that Dr. Schweitzer, of Zurich, had discovered new solvents for cotton and silk. This discovery has enabled us to elucidate several problems in vegetable physiology, hitherto very obscure, and it is hoped that photography may also derive some benefit from the new solvents.

According to Dr. Schweitzer, certain compounds of ammonia and copper possess the property of *instantly* dissolving cellulose, silk, and some other organic substances. The compound in which he first recognised this property, designated by the name of *oxide of cuprammonium*, is obtained by treating basic hyposulphate of copper with *liquor ammonia* in excess. A double hyposulphate of ammonia and copper is produced, which readily crystallises. The mother water, which consists partly of *oxide of cuprammonium*, is the new solvent of cellulose; but its preparation being very tedious, Dr. Schweitzer replaces it by a solution of green subsulphate of copper in excess of ammonia.

M. Peligot has simplified this process, and rendered it more economical. He fills a long glass tube with copper turnings, and pours upon them, in small portions, a given quantity of volatile alkali. Heat is evolved with the production of a blue liquor, formed, probably, of basic nitrate of copper, dissolved in excess of alkali.

When cotton is immersed in this liquid, it dissolves into a thick jelly, which disappears upon the addition of a certain quantity of water, with agitation. To obtain this liquid in a perfectly limpid state, it must be filtered through asbestos, for it immediately destroys paper filters, or rather, the paper is dissolved by this new reagent. The cellulose is precipitated by alcohol, by acids in

excess, by concentrated solutions of alkalies, by honey, gum, dextrine, &c. We can also obtain amorphous membraneous sheets, by simply evaporating the solvent, and these sheets are non-adherent to the surfaces upon which they are formed.

These remarks apply also to silk as well as to cotton, which has also another special solvent in the ammoniacal oxide of nickel. This reagent which is entirely without reaction upon cellulose, or cotton, does not separate from silk even upon the addition of concentrated alkaline solutions, sugar, or gum. Gun-cotton is insoluble in the two solvents above described. M. Fremy has discovered that ligneous fibres, and the sap of trees, are completely insoluble in the cuprammoniac reagent, and that this insolubility is not due to the great cohesion of the molecules of the wood, since it completely dissolves the albumen of *phytelephas*, or vegetable ivory, which is so hard that steel instruments cut it with difficulty. According to M. Payen, the textile fabrics of linen and hemp are soluble in this reagent.

M. Pelouze has also added his testimony to the value of these researches. He has discovered that concentrated hydrochloric acid is an excellent solvent of cellulose, the solution being effected in a few moments with the greatest facility. Water added to this solution forms a brilliant white precipitate, identical with that given by acids in the cuprammoniac solution of cellulose. He has also observed, that if, instead of adding water immediately to the acid liquor, we wait a couple of days, we then obtain no precipitate, the ligneous matter having entirely disappeared by being transformed into sugar (glucose).

Photography thus becomes possessed of several solvents of lignine, and soon of several collodions. These latter will have at least the advantage of dispensing with the costly solvents, ether and alcohol. The difficulty will be, how to prepare them, and experiment only will show. The probabilities of success lie in the following direction, among others :—

We may, for example, spread a layer of cuprammoniac solution of cotton upon a glass plate, and allow the ammonia to evaporate either wholly or in the greater part. Plunge the coated plate into water, acidulated with any acid, and wash it in water; then pour over it an aqueous or alcoholic solution of iodine, or of iodide of potassium. After a few seconds, immerse it in the ordinary nitrate bath, wash it in water, and then expose it in the camera as usual.

If these operations appear tedious, then we may take the solution of cotton in hydrochloric acid, and cover a glass plate with it; allow the acid, which is very volatile, to evaporate, and then immerse the plate in the nitrate of silver bath, after a previous rinsing in water. We shall then obtain a coating of chloride of silver, a very sensitive photographic agent. This method is extremely simple, only it imposes the necessity of preparing the collodion from day to day, because the hydrochloric acid converts the cotton into sugar in a very short time.

It would be easy to suggest other modes of preparing collodion with these new solvents. Those indicated above will serve to show photographers what they may expect from these new discoveries.—*La Lumière.*

RUSSIA AND THE ISLES OF THE OCEAN IN THE STEREOSCOPE.

By M. Ernest Lacan.

Certain persons of grave and dignified bearing, bald-headed and white-cravated, have often reproached me with over-estimating the advantages of photography, and of speaking with too much enthusiasm of its productions. Now, if I can only get one of these cold, calculating gentlemen into my study for an hour, I can, without entering into any discussion, take a little revenge out of him, which is very satisfactory to my pride. I have only to show him part of my stock of photographs collected during the past ten years, and which is daily increasing. At first my gentleman turns over hastily, with a studied and forced air of indifference, the marvels of art I show to him; but he gradually begins to thaw, and stops incontinently at the portrait of some great politician, or artist, or author, he admires, or at some striking landscape or architectural gem. Then he is in my power. Having found out his weak point, I assail him with pictures, I awaken all his sympathies, all his preferences, and all his reminiscences. I intoxicate him through his eyes; and it generally happens that his imagination, turned out of its accustomed routine, runs wilder than my own.

Then I wrap myself up in the mantle of my dignity, look severe, and in solemn measured voice, address him in this style :— " Ahem! You have accused me of extravagant enthusiasm, and here you are yourself excited with a few leaves taken from my portfolio. What will become of you when you read the whole book—when you are transported, as it were, by these works, from one quarter of the globe to the other?—when you visit the most famous ruins of antiquity; when you study leisurely the *chefs d'œuvre* contained in all the principal museums of Europe; when you traverse a street in Constantinople, a lagune at Venice, a canal at Amsterdam, or a square at Madrid or Moscow; when you sail upon the Rhine or the Nile; ascend the summit of Vesuvius or Mont Blanc, and witness the most important occurrences of our times, evoke its ruling spirits, and revive, amid the wreck of ages, the great recollections of the past? All this I can show you, and yet you accuse me of enthusiasm!"

This little speech, which, after all, is only the expression of truth, seldom receives a reply, and I generally make another convert to the charms of photography.

If I make this confession, it is just because I feel at this moment a fit of that enthusiasm for which I am so unreasonably reproached, the cause of which I will proceed to explain.

I have a great passion for travelling. I have already made a good many voyages, and photography will cause me to make many more. Thanks to the plan I have enounced above, I have visited nearly every quarter of the globe where objects of interest await the curiosity of man; but there are two regions which till now have remained closed to me—the extreme north and the extreme south. Now these are opened to us by photography, and we enter Russia with intelligent guides, and proceed full sail to Oceania. Is not this sufficient excuse for making rejoicing and raising a shout of triumph?

For a country, new as compared with other nations, Russia possesses a considerable number of edifices, judging by the proofs under our notice. Of these, churches form by far the greater portion. Nowhere have we ever seen so many; or, to speak more correctly, in this country almost every edifice resembles a church. At St. Petersburg they are generally in the style of our edifices of the seventeenth and eighteenth centuries: this is explained by the date of the foundation of this city, and by the influence of French taste upon the mind of the founder. Those of Moscow are of an entirely different character, such as are found nowhere else. They bear the true stamp of the national architecture.

The imperial palaces, as that of the Grand-duke Michael, at St. Petersburg, are, in appearance, the same as the royal residences of other countries. Formal colonnades, allegorical façades, massive railings, ample proportions, and grave aspect.

The Cathedral of St. Isaac resembles the Pantheon at Paris. The façade has every appearance of being copied from the celebrated composition of David d'Angers. The Museum, called also, I know not why, the Hermitage, is elegant in style and richly ornamented. The squares surrounding these edifices, the streets that lead to them, the river that flows at their feet, are all of immense proportions. Every thing wears an air of belonging to a nation of giants. Whenever a crowd gathers in this good city of Peter the Great, it must always find itself isolated. The thought makes me cold! I shiver while my eye traverses these vast open spaces. Yet I like to muse in the Peterhoff Gardens, beneath the great trees which surround the charming fountain of Alexander. The graceful colonnade surrounding this fountain reminds me of the little temples open to the sky which so frequently adorn the gardens of Italian villas; they want nothing but the sun of Naples.

I decidedly prefer Moscow, and putting aside all the marvels of the City of the Czars, I am tempted to make my entry into the old Muscovite capital. At once all is new, not in date, but in appearance. To enjoy a complete panorama of the city, I mount with the photographer to the summit of one of the minarets or clock towers. From the Kremlin the view is splendid. The gigantic and fanciful forms of the innumerable edifices look like an immense collection of Savoy cakes. It is superb. Viewed nearer, all these edifices present a character of originality which often attains to elegance and grandeur. Besides the Kremlin, itself quite a city, there are at Moscow only churches and convents. If the architecture of these sacred edifices be the expression of the religious sentiments of those who pray in them, or who bury themselves beneath the austerities of a monastic life, then surely nowhere can dissent be so numerous or so varied. Every fantastic form that stone can be chiselled into may be found here. Domes, minarets, clock towers, turrets, form a strange outline against the sky. Such a variety of columns, façades, and towers is here, that it looks like a collection of models of all the mosques, temples, and churches ever built. Such eclecticism! Still these edifices possess a vivid interest. The Convent of Sakolink has the aspect of an enchanted palace, the charming retreat of a fairy princess, an asylum against the temptations, vicissitudes, and annoyances of

the world. In a word, my impression is, that few collections have appeared to me so well calculated to command public attention as this. Our voyage to Oceania will be described on a future occasion.
—*La Lumière.*

Meetings of Societies.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

10, *The Grove, March* 24, 1859.

MY DEAR SIR,

In compliance with your request, I subjoin, extracted from the minute book of our Society, the portion of Mr. Haes's letter which was entered at the suggestion of Mr. Glaisher, and enclose the minutes of our last meeting, held on the 21st instant, together with an abstract of Mr. Glaisher's lecture, delivered on that occasion.

Believe me to remain, my dear Sir,
Most truly yours,
THOMAS R. WHEELER.

Mr. Haes dates his letter, Sydney, December 11, 1858, and writes as follows to Mr. Melhuish :—

"MY DEAR SIR,—I am now able to communicate to you some results of the dry collodion plates which I obtained from you. The plates did *not* diminish in sensitiveness until I arrived at Ceylon, the date at which I wrote to you. I then traced a narrow band all round the plates, of about three-eighths of an inch, which I at first attributed to the partial admission of light into the plate holder; but having exposed plates under circumstances which totally precluded the possibility of light entering, I was led to conclude that the plates were losing their sensitiveness. Dr. Smith, of the Sydney University, has made some experiments upon some of the plates, and we have arrived at the conclusion, that the plates deteriorate *from* the edges; at present, not more than one-third is impressible by light; the change seems to commence at the edge of the plate from which the collodion has been drained. Should you think such information worth communicating to any of the Societies at home, please do so, because I cannot learn that any of these plates have travelled so far, and been kept so long."

AN ordinary meeting of this Society was held on the 21st ultimo, at Mr. Wheeler's, 10, The Grove, the President, J. GLAISHER, F.R.S., in the chair.

The minutes of the last meeting were read and confirmed.

The PRESIDENT presented the report of the Soiree Committee, announcing the kind acquiescence of the Lord Mayor, in reference to holding the soiree at the Mansion House; the 15th proximo being fixed as the date of the meeting, the invited members to assist in making the soiree "a great success."

It was moved and seconded, that the committee originally named be re-appointed, viz., the President, Treasurer, and Secretaries, *ex-officio*, Messrs. Bennock, Heisch, and Wood; Messrs. Stuart Knill, and H. Williams were appointed auditors for the ensuing year.

The President, Mr. GLAISHER, then proceeded to read a paper *On the application of Photography to Investigations in Terrestrial Magnetism and Meteorology, as practised at the Royal Observatory, Greenwich.*

The author commenced by saying that the subject resolved itself into two divisions, viz., the purposes to which photography is applied, and, secondly, the method of application; and he observed that it was necessary to consider somewhat in detail the first part of the question, that the full value of the application of photography should be understood, and that he purposed to confine himself on that occasion to the subject of investigation, reserving the consideration of the mode of application for another evening. The subjects of investigation were those elements in terrestrial magnetism and meteorology which it was considered most important at present to pursue. First speaking of magnetism, he said:—If a bar of iron be suspended by a few fibres of silk, by its centre, it will be horizontal, and will settle in any position; but if the bar be made magnetic, it will at once pass to a definite position, and one end will be inclined downwards. The direction of the magnetic force, he said, undergoes every possible change at the different parts of the earth's surface; and for the purpose of determining and representing the direction, is referred to two planes, the one horizontal, the other vertical. If a magnet be suspended horizontally by a few fibres of untwisted silk, it will rest in the magnetic meridian, and the angular distance between this position and the true meridian is called the variation or declination. The other plane of reference is a horizontal line, the angular distance between which and the inclined position of a magnet, when suspended freely, is called the "dip." In the practice of the observatory, the variations of the dip are made by investigations in the horizontal and vertical components; the variations of the three elements, viz., the declination, the horizontal force, and the vertical force of the dip, are the subjects of photographic application; and when it is considered that if the most minute spider should unfortunately gain access to the boxes containing the magnets, and attach one line of his web to the end of the magnet, that all freedom of motion is destroyed, it is evident that it can be but by some imponderable agent alone that such minute and delicate movements can be registered; and this service is satisfactorily performed by the means of photography.

The author then briefly referred to some application of such investigation; he said the mode of operation was as follows:—Taking the declination as an instance, that when any portion of the globe was sufficiently rich in results, they were laid down in proper positions on a map, and then, with a free hand and good judgment, isophænomenal lines were drawn. A map thus prepared by J. Evans, Esq., was exhibited, showing the lines of equal declination as far as is now known over the world.

A vote of thanks was then tendered to Mr. Glaisher, and a hope expressed that the subject would be resumed at some future meeting of the Society.

W. Nelson Smith, Esq., was elected a member; and the following gentlemen were proposed for future election, viz., Robert Obbard, David Harding, and Andrew Itter, Esqrs. The meeting then adjourned.

LIVERPOOL PHOTOGRAPHIC CLUB.

ON Tuesday evening, the 22nd ultimo, the fourth meeting of the above Club was held at Mr. Keith's Rooms, Lord Street Chambers.

There was a very numerous assemblage of the ordinary members, with several visitors, who took great interest in the proceedings.

After the usual preliminaries,

Mr. FORREST stated, that in pursuance of the requisition that had been made to him, to report upon the progress made by himself, and other members of the committee, appointed for the purpose of permanently burning photographs into the surface of glass, he had brought several specimens of his labour, which, though very far from attaining the excellence he sought, had revealed fresh arcana, that would involve much deep reflection, with renewed experiments and increased exertions. He had found that the fire, though it destroyed all traces of the film, yet impaired nothing of the delineation. The loss sustained by the heat was in the force and vigour only, that, as in the case of the negatives, first weakly developed by iron, to be afterwards intensified by pyrogallic acid —so the basis of the photograph was in the face of the glass; all that was needed was some reagent, to give force to the image, deteriorated as it was by heat; frequently they found their ordinary coloured glass required passing three times through the fire, to impart sufficient depth of colour to it. Acting upon this, he had sought to give greater boldness to the photograph, and had discovered that, in a well-developed positive, sufficient amount of silver was precipitated on the surface of the glass to serve as the nucleus for a farther deposit of a very thin coating of copper by means of the galvanic battery. The copper so thrown on the surface would be perceptible in the specimens now laid before the meeting; in the half of one, the mere photograph would be just traceable, in the form of a faint outline; whereas the other half of the stereoscopic picture that had been electrotyped, would be perceived to possess much of the black intensity of ordinary transparent positives. He might mention, that to remedy the great inconvenience of putting so small articles into a large kiln or furnace, he had found it suffice to place a sheet of iron on the fire, with the glass to be fluxed on the upper face of the iron; another sheet of iron was just supported above it, to keep it from actual contact, and, by heaping a moderate amount of fire over it, the fusing of the surface of the glass was speedily accomplished.

Mr. KEITH suggested that as the lines were to be rendered more intense from the oxide of copper, a readier way of imparting it to the silver on the glass would be to bleach the positive with the bichloride of mercury, and then to blacken, not merely with ammonia, but with ammonia-nitrate of copper.

Mr. GLOVER objected to this, inasmuch that though the blackening of the so-produced negative might be promoted by the chemical advised by Mr. Keith, yet he doubted if any appreciable amount of copper would be precipitated upon the silver.

Mr. COREY considered that at least the action of the mercury would greatly facilitate the deposits by the electrotype.

Mr. COOK exhibited what might be considered the perfection of photographic barrows, upon which much time and outlay had been expended. It was about five feet in height and four by two square.

On arriving at its destination, four legs, which admitted of raising it to any height, were let fall by releasing so many screws. The wheels were now removed. One side, on being let down, revealed the coloured window; the opposite side, when lifted up and supported, enabled the operator to sit under it, while enveloped with a drapery buttoned round him, thus excluding all daylight. The whole of the interior, forming a spacious operating room, was at his disposal. When closed, every needful article, such as chemicals, camera, folding legs, *et hoc genus omne*, were enclosed within.*

Mr. Corey said he considered it only fair to one of their members, to bear testimony to the superior excellence of his collodion. He held in his hand a negative which possessed every requisite that could be desired, and yet was the result of exposure of only two minutes in a very dull light, and developed with pyrogallic and citric acids only, without needing the addition of any more silver. He had tried many samples of collodion of admirable quality, but had found none equalling Mr. Berry's for sensibility, minuteness, and intensity.

The meeting separated at a late hour.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The usual meeting of this Society was held at the Chorlton Town Hall, on the 9th ultimo, the Vice-President in the chair.

At this meeting, in accordance with the rules, officers for the ensuing year were proposed and other arrangements made for the annual meeting, which will be held in April.

The President sent to the meeting a number of views, taken by Mr. Paul Pretsch's process, which were much admired.

Several gentlemen were proposed as members for election at the next meeting.

Mr. Rogerson then read the following paper on *The Enlargement of Photographic Pictures, either Positive or Negative*:—

The subject for our consideration this evening is the enlargement of photographic pictures, either positive or negative. My attention was first drawn to the subject by being called upon to make large negatives, at times when it was utterly impossible to do so, from the feebleness of the light; but, still, comparatively easy to make one of one-sixth or one-fourth size. Now, if we can increase the size of these small pictures successfully, it will be a great boon both to the amateur and professional:—to the amateur, by decreasing the bulk of his apparatus, for he may carry his camera in his pocket, with a few dry plates, his stand may become his walking-stick, and thus he may extend his rambles, looking for nature's choice subjects much farther than he would otherwise feel disposed to do.

The advantages to the *professional* portrait taker are such that I think can only be fully appreciated by him, for he does not require me to tell him that large pictures take considerably longer time for exposure than small ones, thus increasing the chance of failure; but this is not the worst:—portrait lenses, as you are aware, are made to take in a large angle, thus producing distortion, varying in amount with the size of the lens, the larger the lens the greater being the distortion. It is not unusual to hear parties say, who have had their portraits taken with a large lens, "Oh, it is much too stout for me; I am not near so fat as that." I do not bring *sitters* forward as witnesses at all times to be relied upon, for they make some strange assertions often; but in that they are quite correct, the picture is much stouter than the subject.

Now, as to the enlargement of pictures, I think you will see that there is no great difficulty. All of you will have seen photographic exhibitions with the lantern, and you know how correct we have an enlarged picture—how it strikes as a reality.

These pictures are *mostly* taken with small lenses, stopped down as well, thus lessening the angle and preserving the fidelity.

Now, you have only to imagine the sheet or screen to be a sensitive surface, and you then have an enlarging apparatus; and I do not yet see why we cannot at any time enlarge to the size of the original without producing distortion. There are persons who say we can't; and if there are any here to-night, I hope they will give their reasons.

The next thing I wish to mention, is the sort of light to be used; I think that artificial light will be the best, because we can keep it constant for a given time; those who have printed much with gas light know how easy it is—for the time, once ascertained, does for the whole lot that he may have on hand.

The apparatus now before you, consists of a small camera, with an ordinary quarter-plate lens, portrait combination, an expanding bag, to connect the lens with a large camera back, as large as is needed; and both ends contain the usual carriers. These are moved on a frame, containing two screws for focussing, by means of which the operator is enabled to alter either end of the camera for focussing as required; by the aid of the two screws, he can focus either for enlarging or diminishing, without moving his position; both are needed to bring the camera into focus, as you will see by examination, and with one screw, two persons would be required to arrange the apparatus. A small glass positive was fixed in the small end of the camera, and by the aid of a gas light, passed through a condenser, a magnified copy was plainly visible at the other end, in correct focus and proportions. A negative was then treated in the same way, the effect of which was very gratifying to the members, who regretted that there was so little time remaining to discuss the subject, owing to the time required by the routine business of the meeting.

Mr. Rogerson stated that a small positive could be placed in the camera, and a magnified picture taken with a good gas light in about five minutes' exposure on wet collodion, and that the lens then attached to the camera was one of the cheapest kind, only costing fifteen shillings, which he placed there purposely to show the effect by the most common appliances, and yet any person could see for themselves that the result was correct. He claimed no merit for any thing not known before, except that he thought the focussing arrangement was an improvement.

The thanks of the meeting were given to Mr. Rogerson for his paper, and to the Chairman, which concluded the business.

* This barrow was noticed in our leader of 1st December of last year.—Ed.

Letters to a Young Photographer.

No. VII.

My Dear Eusebius,

You are now about to greatly extend the sphere of your operations. That camera which you have been so wistfully eyeing and toying with for the last two months, is now to become your instrument of pleasure and toil—of success and disappointment; of as much care as besets the wearer of a crown—of as much delight as Pygmalion enjoyed upon completing his statue, which, to crown his happiness, he sought to animate. The charm of the life of an artist lies in his creative power; it is this faculty that enchants the budding photographer. He can create pictures, not by the slow and tedious ways of the painter, but by the magician's power which mocks at time and space. It is a pouring-on of charmed compounds, a touch of a spring, another pouring, and lo! there stands revealed a picture in all its charms of light, and shade, and detail!

You, who are so diligent a reader of this Journal, must have acquired some inkling of *processes*. There are plenty of them, so take your choice. Which shall you choose? Which do I think best? Probably they are all best; inasmuch as good pictures may be obtained by employing either one or the other of them. For in-door work, I, of course, employ wet collodion, pure and simple; while for out-of-door operations, I am the slave of *dry* collodion. I shall describe all the methods in their turn, but at present I shall discourse on other matters. As, at the outset of your career, you must inevitably waste a good quantity of materials, I must recommend you to work, for the present, your stereoscopic camera. With this you will be able to obtain a complete initiation into the *modus operandi* of the art, and your failures will not cause you so much regret as if you spoiled plates twelve by ten inches or thereabouts.

In commencing operations, you must proceed calmly and cautiously; avoid becoming excited, as most young photographers are apt to do; but proceed deliberately, and with a clear notion of what you seek to accomplish, and of the means also by which you expect to attain the desired result. Order and cleanliness are prime photographic virtues. There must be a place for everything, and everything must be kept in its place; and always keep the key of your operating room in your pocket when you lock it up; for if, by chance, officious, prying Betty should find her way in when your back is turned, she is sure, like every daughter of Eve, to taste forbidden fruit, and will most probably prefer a dose of cyanide, whereby a coroner's inquest will ensue, and you will be branded—"that murderous photographer!"

How lucky you are that you did not commence photography some ten years ago, when collodion was as yet undreamt of. Your choice would have been divided between daguerreotype and calotype. To the first of these I devoted my early affections most ardently; but it has gone the way of all things, and now lies buried

in the tomb of the Capulets, to be exhumed some day, probably, and clothed *in colours.* In calotype you would have had a choice between plain paper and waxed paper; but with collodion at your command, you would have looked scornfully upon all other vehicles or media. For a while you might have given yourself up to the dawning charms of albumen, still you would not have failed to become captive to collodion, sooner or later.

It will not be advisable for you to attempt making collodion or any other chemical in your present stage of initiation, it would only distract your mind from the main business, and digressions are not favourable to progress. I have before me a very excellent Treatise on Photography, which exhibits a singular talent for digression. The writer commences with telling you how to coat a plate with collodion: then he occupies several pages in describing the process of its manufacture; he arrives at the nitrate bath, then a dozen pages or more are occupied about silver, nitric acid, &c. Presently he introduces the camera, and then some thirty pages are occupied with a discourse upon light. He speaks of colours, and lo! a lengthy disquisition ensues upon a new theory of colour. Proceeding in this digressive style, it is with the utmost difficulty that the reader can contrive to dovetail the various pieces of instruction necessary to obtain a picture. So, in your practice, be careful to avoid digressions. Take a day previous to that upon which you intend to work your camera, and devote it to preparing your chemicals, so as to have every thing ready, and at hand, when operating. A little foresight and preparation will save you many untimely digressions, which are the sure precursors of failure and disappointment.

I hope your operating room is in good order, as I so frequently have impressed upon you; see that no light penetrates except through the yellow glass, and hang a heavy curtain over the door, *outside,* which will serve to exclude vagrant rays of light passing through keyhole or crevice. It is not a matter of utter indifference as to which part of the room you will appropriate to the various stages of a process. I prefer plenty of light, of the yellow sort, both for coating a plate, and for developing; but the places of these two operations had better be as wide apart as the space admits of. Your room must be effectually ventilated. I do not like a room with a chimney, because when no fire is kept, there is generally a downward current of air, loaded with sooty particles, which distribute themselves most provokingly where they are not wanted. If your room is sufficiently lighted through yellow glass, there will be no need of any kind of combustion, either from gas or taper, being carried on within it; and that I consider to be a very great advantage.

Water of course you have in abundance, "laid on;" but you must also provide a two-gallon bottle of distilled water, which, however, is best kept in a covered vessel with a tap to it. The waste pipe of your sink should be made to pass into a large cask or barrel, so as to recover the waste silver from the washings. Into this barrel you will put some *liver of sulphur,* in order to convert the salts of silver into *sulphides,* as I shall explain when I come to treat of *residues.* There ought to be another cask communicating with the first, containing also liver of sulphur, so as to make sure of precipitating all the silver. About six inches from the bottom, a tap must be inserted, to draw off the supernatent water; the sulphide of silver will be found precipitated at the bottom of the cask, in the form of a dense black powder. Every bottle should be labelled with the name of its contents; this is of the utmost importance, as most of the solutions employed are colourless; this is the case with solutions of nitrate of silver, cyanide of potassium, hyposulphite of soda, and pyrogallic acid; it will save you some trouble if these solutions are each kept in bottles of different sizes and shapes.

Keep your camera in a dry place, out of the dust, and before you proceed to use it, wipe out the inside carefully, and clean the lenses with a piece of chamois leather. You must place the camera "in position" before the object you intend to copy, because if you neglect doing this while operating with wet collodion, the plate will become spoiled during the time you are "fixing" the camera.

If you essay taking portraits, you will probably discover, after a great waste of time and materials, and no little patience, that in order to obtain a good picture, one in which the *chiar' oscuro* is artistically arranged, as much depends upon the manner in which you arrange the light to fall upon your object as upon all your manipulations. This is a point very much neglected among photographers; hence that mass of flat, insipid, or heavy blotty faces, we meet at every turn in exhibitions and on door-posts. Now it would be impossible for me to give you such directions by letter, as would enable you to surmount this difficulty, you will probably have to master it for yourself, since the "accidental lights," as the painters term them, will be governed by the aspect of your room. I may, however, say, as a general rule, that one side of the object must be more strongly illuminated than the other; that the amount of strong direct light upon the object need not be very great, but that there must be abundance of reflected light thrown on the object by surrounding screens.

Photographic Glossary.

Glycerine—A sweet syrupy liquid, colourless and inodorous, miscible in all proportions with water and alcohol, but nearly insoluble in ether. It is obtained from fatty matters, and is a waste product in the manufacture of stearine. It has been suggested as a preserving agent in the collodion process.

Glycyrrhizine—A sugar obtained from liquorice root. It is soluble in water and in alcohol. With most of the metallic salts it forms precipitates. It is added to collodion with the view of increasing the density of the blacks of negatives, and to developing agents with the same object.

Heliography—A Greek term, signifying *sun-drawing,* employed to comprehend all the various photographic processes, daguerreotype, talbotype, &c.

Hydrate—Water sometimes enters into chemical combination with bodies, the resulting compounds being termed *hydrates.* The chemical action is often very energetic, and much heat is evolved, as in slaking quick lime. After the water has combined with the lime, the slaked lime is a hydrate of lime. Oil of vitriol is a hydrate of sulphuric acid. In the formation of crystals, water enters into their composition, but in a less intimate manner than when hydrates are formed; the water of crystallisation may be expelled by heat.

Hydriodates—Combinations of hydriodic acid with bases, forming salts. They differ from iodides in containing water of crystallisation.

Hydriodic Acid Gas—A compound of equal volumes of hydrogen and iodine, which combine without decrease of volume. It is colourless and highly acid; it fumes in the air, and is very soluble in water. With the bases it forms hydriodates.

Hydrochloric Acid Gas—Called also "Muriatic Acid Gas." It is composed of chlorine and hydrogen. Water dissolves 480 times its bulk of this gas, and this solution forms the hydrochloric acid of commerce. When pure it is colourless. Mixed with nitric acid it forms *aqua regia,* the solvent for gold. It is occasionally employed in photography.

Hydrochlorates—Combinations of hydrochloric acid with the bases, which form salts. The principal one used in photography is the hydrochlorate of ammonia.

Honey—This well known substance is employed in photography as a preservative agent in the collodion process, to keep the film in that humid state considered essential for obtaining successful results. Honey appears to owe its photographic value to its hygroscopic qualities.

Hydrometer—An instrument employed for measuring the specific gravity of fluids, sometimes termed an areometer.

Foreign Correspondence.

Paris, March 24, 1859.

There is nothing new under the sun: not even photography. What is new is old, and what is old becomes new again. We have been pluming ourselves upon one of the wonderful discoveries of the present century, which we call *photography;* and just as we think we have capped the climax of perfection, up starts a ghost of the seventeenth century, who says, "That's mine! ye puny triflers, that—and much more, that ye vainly seek to discover." In a book recently published by M. Edward Fournier, entitled *Le vieux neuf,* the following remarkable passage occurs:—"At this period, an Utopian, one Thiphaigne de la Roche, discovered the daguerreotype, not the daguerreotype of the present day, but that of the future, in which the colours, as well as the images of objects, are reproduced—the daguerreotype perfected, such as it may become to-morrow, or such as it may not be for another century." The description of the process given by Thiphaigne is rather lengthy; but it is so curious and interesting, that I cannot resist the temptation to quote it entire.

"It is well known," he says, "that the rays of light reflected from different bodies form a picture, by depicting their images upon the surface of polished bodies — as, for example, upon the retina of the eye, upon the surface of water, glass, &c. Ingenious minds have essayed to fix these fleeting images: they have compounded a very subtle, viscous substance, which quickly dries and hardens, by means of which a picture is produced in the twinkling of an eye. They imbue a piece of linen with this substance, and expose it to the objects they wish to depict. The first effect on the linen is that of a mirror, in which may be perceived every object, distant or near, of which light forms the image.

"But what the glass fails to do, the linen, by means of its viscous coating, accomplishes. The mirror faithfully reflects objects, but retains none: our canvas reflects them no less faithfully, and retains them also. This impression of an image is the work of a moment, so soon as the linen receives it — it is then removed to a dark place; in about an hour, the sensitive coating becomes dried, and then there is a picture, more truthful and precious than any that art can produce. We obtain from the purest source, from light itself, the colours, which painters derive from different substances that time never fails to change. Accurate design, variety of expression, every touch, gradation of light and shade, the rules of perspective, we leave now to nature, who, with unvarying finger, traces upon our canvas the images perceived by the eye; and even leads us to doubt whether what we consider as realities are anything more than a species of phantoms, which cheat our vision, our hearing, and our touch — in a word, which cheat all our senses."

Burying the secret with him in the grave, we are half inclined to exclaim with the poet —

> "Call up him, who left half told
> The story of Cambuscan bold."

It would be different to describe photography in more correct terms than those employed by this Utopian, who dates from the year 1670.

There seems to exist just now, among photographers, a strong determination to perfect a method of positive printing, especially with regard to toning and fixing. M. Jobard, of Dijon, has communicated the following to the *Académie des Sciences*:—"When the proof is removed from the printing frame, immerse it in a neutral bath of hyposulphite of soda, of the strength of four ounces to one pint of water, and allow it to remain from fifteen to twenty minutes; wash and dry it; then immerse it in a bath composed of water thirteen ounces, bromide of potassium three drachms, and iodide of potassium two drachms; remove it, and hang up to dry."

Thus far the proof will not have altered in tone. The toning bath is composed of water thirty-five ounces, sel d'or fifteen grains. When immersed in this, the proof changes rapidly in tone, and passes from red to brown, violet, purple, and intense black. The toning may be stopped at any desired stage. Two proofs treated in this manner, exposed to the most noxious influences of light, heat, moisture, and foul exhalations, still remain intact, whilst others treated by the ordinary methods, exposed to similar influences, were destroyed.

M. Legray has been induced to modify his formula for toning and fixing positives, in consequence of many persons who tried it having failed of success. This failure M. Legray attributes to the great concentration of the bath, causing its action to be too rapid, and rendering it difficult to seize the proper moment for removing the proof from the bath. His formula, as modified, is as follows:—

Distilled water	3½ pints.
Chloride of lime	15 grains.
Chloride of gold	15 „
Chloride of sodium	15 „

The proof may be allowed to remain in this bath for half an hour, without detriment, and as the progress of toning is slow, the proofs can be removed when the exact degree is attained. It must be remarked, however, that as this bath contains but a very small proportion of gold, it will only serve for about twenty proofs of quarter sheet size; the bath must be renewed as required by the addition of fresh chloride of gold and chloride of lime, but it is better to make an entirely new bath when the old one is exhausted. The old baths may be treated with sulphate of iron to recover the gold remaining in them. Proofs thus treated are very pure in the whites, and quite permanent. The well-known bleaching action of chloride of lime removes any discoloration in the organic substance of the paper, while permanency is secured by no nitrate of silver being allowed to remain in the texture of the paper, as it is immediately converted into chloride upon immersion in the bath.

As the preservation of sensitive positive paper is now a subject of much interest, I may as well mention a suggestion made by M. Gaumé.

The sensitised paper is dried as quickly as possible before the fire, if the weather is damp, and enclosed in a box lined inside with a coating of plaster of Paris, perfectly dried in an oven or stove. The plaster may be in slabs, so as to be easily removed and dried from time to time, as they will absorb the moisture from the atmosphere. The sheets of sensitised paper should not be laid in a pile upon each other, but separated, so that the intervening air may always be dry. The plaster being very hygrometric, the air in the box will continue perfectly dry for a great length of time, provided the box is well closed. By this method M. Gaumé confirms the conclusions MM. Davanne and Girard have arrived at, namely, that the discoloration of sensitised positive paper is due to the action of moisture and the presence in the atmosphere of deleterious gases. M. Gaumé has also submitted some modifications of his process, published in August last, for taking positive proofs on paper prepared with a solution of gutta percha in benzine, which he now applies to negatives. These are prepared exactly as the positives, with this exception, that he adds to the albumen, instead of chloride of sodium, two to three per cent. of iodide of ammonium and one of bromide, and dries the paper before the fire. After exposure the negatives are developed with gallic acid, to which some drops of aceto-nitrate of silver are added.

The proofs are fixed with hyposulphite of soda, ten ounces to a pint of water.

The paper is sensitised by immersing it in ordinary aceto-nitrate of silver, and afterwards washed in two or three waters, and dried at the fire.

If there be any signs of resinification after this operation, the proof is immersed for a few minutes in benzine, which removes the greater part of the gutta percha. If the proof is very strong, wax it as usual; if it be weak, leave it semi-transparent.

MM. Davanne and Girard have published, in continuation of their report on positive printing, their conclusions as to exposure in the printing-frame, or, as it is termed, *insolation.* One point at which they have arrived possesses strong interest at the present moment, when the question of "bottled light" is under discussion. In repeating the experiments indicated by M. Nièpce de St. Victor, they never succeeded in producing the effect of solarisation described by that gentleman; for whenever they took a sheet of paper, sized or unsized, and exposed it to light in the printing-frame, and then floated it on the nitrate of silver bath, no appreciable result could be discovered; consequently, they cannot, even after the most careful experiments, confirm M. Nièpce's views as to the absorption or storing up of light by paper. These gentlemen delicately remark, that possibly they operated under unfavourable conditions: "perhaps the light was not sufficiently intense," &c.; but they confidently assert that the exposure of paper to light, previous to sensitising, exercised no influence upon the production of the positive proof.

Correspondence.

COATING PLATES BEFORE COLLODIONIZING.

To the Editor.

Sir,—With reference to a subject which has lately been discussed between us, viz., the possibility of producing from the fibre of different grasses, &c., a form of pyroxyline suitable for the dry process, I may mention that the experiments have now been discontinued, since it appeared certain that the film so made, although sufficiently porous and adhesive, was wanting in sensitiveness to the darker parts of the object, and tended to exaggerate the contrast between the extreme tints. Hence, although answering well enough for printing transparencies, it failed in producing a perfect camera picture.

A very important advantage would be gained if the same collodion could be employed both for the wet and dry processes, and this desideratum seems likely to be realised. The formula for pyroxyline, which I have lately submitted to a committee appointed by the Photographic Society, has the merit of being very adherent to the plate, and good dry pictures have been taken with collodion so prepared. The use of gelatine as a preliminary coating to the glass, recommended by Mr. Dorrington, attaches the film still more firmly, but probably a better substance for that purpose is caoutchouc dissolved in benzole.

I find that I am not the first to suggest a varnish of the above kind. Mr. Barnes, in the second edition of his "Dry Collodion Process," has mentioned India rubber with other similar substances. In his preface he complains that his just claims have been overlooked, but if so, it has been done unintentionally. Possibly his suggestions are somewhat to

numerous to be easily intelligible, but many of them are exceedingly practical, and the work is one which ought to be consulted by all who turn their attention to this branch of the art. Mr. Barnes's views on the use of an ordinary sensitive collodion for the dry process, and the employment of a subjacent layer to retain it upon the glass, appear likely to be carried out extensively, and very excellent negatives have already been taken in that way.

If any of your readers are interested in the matter, and can make it convenient to attend the next meeting of the Photographic Society, on the evening of April 5th, I purpose, in the absence of more pressing business, to exhibit two or three plates which have been sent to me, and to make a few remarks with the hope of originating a discussion.—Yours, &c. F. HARDWICH.

King's College, March 24th.

PRINTING GLASS TRANSPARENCIES.

To the Editor.

Sir,—Do you know if the simple process of printing glass positives, by coating the glass with albumen, and then proceeding in the usual way as with paper positives, has ever been tried? I dont see why it should not succeed, and save a vast deal of bother of working by a dry process.

The idea has just been hinted to me, and may prove useful to our photographic brethren.—I am, yours, &c. J. S. MOON.

Islington, March 8, 1859.

[Would not your proposed method be a "dry process?" We do not see in what way it would be more simple than any now in use. You would find the film of albumen alone a very troublesome affair to get even and free from specks of dust. You must also remember, that the exposure required would be much longer if no developement were adopted; while the certainty of operation would not be any greater, as you could not, as with paper, bend up a part to see how the printing progresses. Possibly, however, some of our readers may see their way to utilize the hint, although we do not. Another objection would be, in there not being any ready way of pouring free nitrate of silver.—Ed.]

QUICK PROCESSES.

To the Editor.

Sir,—I take the liberty of sending you a paragraph from a newspaper, and I should feel greatly obliged if you will state by what means you think the pictures referred to are done.

I observe in your last number a note on Messrs. W. & D. Downey's pictures, taken at the opening of the Jarrow Docks. It would be very interesting to know something about the process, and the lens they employed in its production.

Many of the stereoscopic slides by Mr. Wilson, of Aberdeen, must be taken by some very quick process. It would be a boon to photographers, if such gentlemen as Messrs. Kibble, Wilson, and Downey, would publish their processes, and state what lenses they use.—Yours, &c.

Glasgow, March 17, 1859. J. R. A.

[The individual referred to in the newspaper paragraph which you enclosed, is not a producer of micro-photographs, only a seller of them. We were the originators of them, and you will find full particulars of the process for their preparation in the *Liverpool and Manchester Photographic Journal* for 15th November, 1857, No. 22, in which a paper read by us, at the Photographic Society, appears.

We trust that your hint will obtain the information you desire from the gentlemen named.—Ed.]

PRESERVATIVE CASES FOR SENSITISED PAPER.

To the Editor.

Sir,—Among things which I did not get speaking of when I had the pleasure of meeting you here, were cases for preserving sensitive paper, of which I had then two in hand. They both, amusingly enough, consist of japanned tin cylinders, with internal cylinders of perforated zinc, to contain chloride of calcium, and on which to roll the paper.

One of the two which I had made has a valve in the centre of the brass screwed cap, through which the air may be abstracted by an air pump, for the further security of the paper. The other case is furnished with two valves at the same end, to afford facilities for replacing the atmospheric air in the case with carbonic acid gas.

The carbonic acid is easily produced, and conveyed by a flexible tube, and is blown through one valve (the other being also open), until the atmospheric air has been displaced by the denser carbonic acid.

I have not time at present to say more, than that I may be able to-morrow to send a photograph of one of my cases, which in form seem so nearly to correspond with the description in your Journal of the 15th, the reading of which at this moment has induced me to write to you.

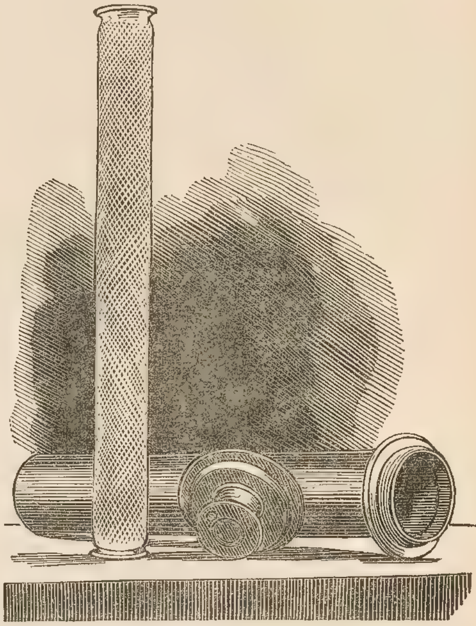
Yours, &c.

March 15, 1859. WM. CHURCH, Jun.

Sir,—I now send a hurried photograph of one of my preservative cases referred to in my note of yesterday. It scarcely calls for explanation. The screw of the cover works down on a washer of leather (india-rubber does not seem to answer with a screw), smeared with lard, or what I think is better, india-rubber, melted on a metal plate by means of heat. The zinc cylinder has a removable cap at each end to admit the chloride of calcium, or to replace it when it has become damp. When in use, the zinc cylinder is covered with porous paper, properly secured to prevent particles of the chloride from getting in contact with the sensitive paper. The removal of atmospheric air, or replacing it by carbonic acid, have not yet been sufficiently tried, to admit of my saying that either will be of additional advantage.

I hope such a thing as this has not been patented, and regret that I did not sooner give you the means of publishing it.—Yours, &c.

March 16, 1859. WM. CHURCH, Jun.



OPTICAL ARRANGEMENTS, &c.

To the Editor.

Sir,—1. Will you, with your usual kindness, please to inform me in your next Journal the best method of removing the small round discs from microscopic glass, in order to save the glass, a quantity of microscopic objects having been badly mounted and spoiled from a variety of causes.

2. Will you, at the same time, inform me what you consider the best method of rendering very fine old collodion sensitive as possible, without destroying its fine quality, for small locket portraiture, with the quantity to be done at once, proportions, ingredients, &c.

3. In trying to concentrate the rays of light from a lamp upon a bull's-eye lens, three inches diameter and five inch focus from the flat surface, and those again upon a double convex lens, eight inches in diameter and sixteen inch focus, what should be the relative distances to give the best and most concentrated light upon a negative portrait, in order to take a transmitted positive by artificial light—that is, the distance of the lamp from the bull's-eye, the bull's-eye from the large lens, and the large lens from the portrait, say three inches square?

You will greatly oblige if you can give me a reply to these three queries in your next, as I much wish to try some experiments of the kind referred to in your last, and time is just now an object with your constant subscriber. VERITAS.

London, March 21, 1859.

[1. If mounted with Canada balsam, put the slides into a wide-mouthed bottle, and cover them with camphene, benzole, or turpentine, fit in the stopper or bung, and let them soak; the thin glasses will then readily come off. If the covers have been cemented on with gold size, soaking in a strong solution of soda will do—liquid glue (shell-lac), or asphalte, will yield to the former solvents.

2. Your question is rather obscure. If you wish to *restore* old sensitised collodion, we know no better plan than that formerly suggested by Mr. Crookes, viz., immersing in it a slip of silver foil, until discoloration ensues—but if you mean to sensitise plain collodion for positives, take alcohol (S.G., 816) one ounce, iodide of cadmium eight grains, iodide of ammonium six grains, bromide of ammonium four grains. Add one part of the preceding to three parts of plain collodion. This is Mr. Hardwich's formula. The quantity prepared at once must depend upon your consumption; it is very sensitive when freshly mixed, and keeps fairly for about a month, with but little loss of quickness.

3. Place the bull's-eye very near to the lamp—so near that the rays *slightly diverge* after passing through it (this would be about four inches distant in your case); place the other lens as near as possible to the bull's-eye, but so that the *cone of light* just fills the *entire area* of the larger lens (probably about six or eight inches off from the bull's-eye); the rays should proceed nearly parallel, or only slightly converging from the large lens, and the negative may be within a couple of inches of it.

Your bull's-eye is of too long a focus—one of two and a-half inches diameter and three inch focus would be better; of course, placed closer (say within two inches) to the lamp. The purer the light the better, quality being more important than quantity in this case.—Ed.]

ON COVERING MICRO-PHOTOGRAPHS.

To the Editor.

Sir,—I am rather surprised at the difficulty experienced by your correspondent "Veritas" in this matter, and think it must arise entirely from his mixing his balsam with turpentine. I have always been in the practice of allowing a drop of balsam to simmer, *not boil*, on the photograph resting for a minute or two on the warm mounting table, and then of dropping on it the thin glass cover, previously warmed, forcing out the superfluous balsam by slight pressure.

You will see the effect in the two specimens enclosed, which I forward, for the additional reason that they have been made without any previous practice in the art of photography, by carefully following out the directions contained in your interesting paper, read before The Photographic Society, 5th November, 1857.—I am, yours, &c.

Aberdeen, March 21, 1859. H. A. S.

[The specimens received evince the skill of the operator, but are rather heavy in the shadows; we would recommend to him a trial of the iron developer, given in our present leader, as likely to produce less violent contrasts of light and shade, with the collodion he employs. We are obliged for his reply to "Veritas,"—we are are always pleased to find correspondents assisting one another.—Ed.]

PRACTICAL DETAILS RELATING TO NEGATIVES AND PRINTING.

To the Editor.

Sir,—Would you kindly tell me in your valuable Journal (1) in what proportions should I use citric acid instead of acetic acid; this would be useful to many to know, as citric acid is so much cheaper and in a more convenient form than acetic acid. 2. What is the best strength for a salting solution, both for pure albumen, albumen half diluted with water, and for plain paper, using with all the papers a sixty-grain exciting solution. 3. When using an iron developer for negatives (collodion) is the pyrogallic acid used immediately after the iron solution is washed off, or after the fixing: in such case is anything gained by employing the proto-acetate instead of the proto-sulphate of iron? 4. Your opinion of the paper marked "La Rive," and where it can be obtained.

After troubling you so much, allow me to thank you most heartily for the extremely kind way you have sacrificed your time to the troubles of numerous dull-headed photographic brethren, including

Yours, &c. BRUIN.

[1. Generally, about *one grain* of citric acid will be required where *thirty minims* of glacial acetic acid would otherwise be used—this is, however, not an absolute proportion under all circumstances—when used with pyrogallic, in cool weather, one grain of citric acid to two of pyrogallic, in one ounce of water, is sufficient—in warm weather, equal proportions—but in *hot* weather, the citric acid is invaluable, and then two grains may be employed to one of pyrogallic acid. For *moist* plates the addition of a little alcohol is a requisite, in order to cause the solution to flow easily over the plate; but for dry plates alcohol is not only needless, but detrimental.

2. It would be rather rash to assert that any particular strength of salting solution is *the best*, but we recommend the following for use with a sixty-grain to the ounce sensitising bath, viz.—

	Pure albumen.	½ alb. & ½ water, or water + gelatine 2 grs. to each ounce.
Chloride of ammonium......	10 grains	—15 grains.
,, sodium............	12 ,,	— 18 ,,
,, barium............	20 ,,	— 30 ,,

The above will give nearly the same quantity of chloride of silver whichever salt is employed.

3. See our Leader. If all the details are *well out* with the iron developer, it is best to fix *before* using the organic developer; but if the half-tones are rather weak from under exposure, and *provided there are no symptoms of fogging*, then the pyrogallic acid may be employed advantageously after washing off the iron, but *before* removing the iodide of silver.

4. Personally, we consider the paper you name *too tender*, but many operators like it. You can purchase it from most dealers—for instance, Horne & Thornthwaite, Hockin, Knight, Spencer, Sanford, &c., &c., all keep it.

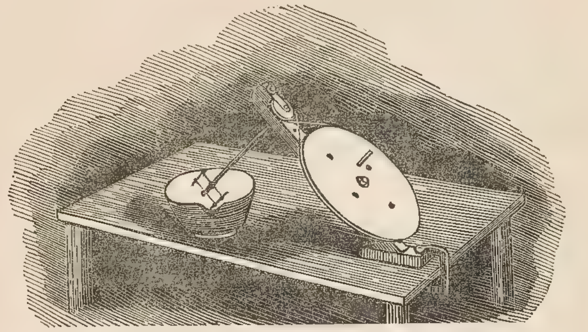
Our object is to be of service to our readers; but, apart from this, we feel a *pleasure* in so doing, especially towards brother photographers.—Ed.]

APPARATUS FOR FROTHING ALBUMEN.

To the Editor.

Sir,—In mechanically preparing albumen for photography the thorough and complete disintegration of every particle is indispensable.

By the ordinary fork process this is generally a long and tiresome job. I long contemplated making a machine to assist in the work, and have recently constructed a rough one, which answers completely, taking six minutes only to beat the albumen up instead of twenty-five, and producing a much better article, so much so that I think it would be impossible to make it as well by the fork.



The apparatus is simple: a suitably shaped beater is rotated amongst the albumen in a basin (slowly at first, the speed being increased as the froth rises), by means of a pair of pulleys, in the proportion of about six to one, connected by a crossed band; a speed of upwards of five hundred revolutions per minute being easily attained. The standard, carrying the pulleys and beater shaft, slants at an angle of about forty-five degrees, and may be fastened to a table or board by a clamp.

When in use the large pulley is turned by the right hand, the basin containing the albumen, &c., being held in the left, so that the beater can have the proper dip, and every bit of the froth subjected to it effectually.

The enclosed print will show you the arrangement.

21st March, 1859. M. NOTON.

NEGATIVE COLLODION FOR COPYING AND LANDSCAPE PHOTOGRAPHY.

To the Editor.

Sir,—You will greatly oblige me by giving in your next Journal a formula for the best negative collodion chiefly to be used for copying and landscape photographing. It should be rather *quicker* than the ordinary collodion purchased in shops, have fair keeping qualities, and give a very dense negative, developed with protosulphate of iron, and strengthened with pyrogallic, &c.

What do you think of an iodizer containing a well-balanced quantity of several iodides and bromides? I have used a collodion said to be so iodized, it gives a splendid negative, is very quick, and keeps well, but the person to whom the formula belongs has an objection to open his heart and memorandum book to his brother photographers.

If you would also state where I may obtain the ingredients, you may be kind enough to recommend, you will further oblige.—Yours, &c.

Manchester, March 10, 1859. IN-QUEST.

P.S.—I have read Hardwich thoroughly upon the point, but cannot come to a satisfactory conclusion as to *the best*.

Where shall I find a good account of your honey process? I wish to try my hand at the "*sticky mess*." I have read the letter in Vol. VI. No. 88, but I cannot gather sufficient for my purpose.

[We have not yet learned that *the best* negative collodion has been realised; certainly we are not presumptuous enough to lay claim to a knowledge of its formation. The fact is that our correspondent asks for somewhat of an anomaly, in requiring one to be equally good for "copying" and for "landscape photography," and to be unusually "quick," and yet stable; moreover, he does not specify whether he means for a dry or a humid process.

For copying, we prefer an old and somewhat glutinous collodion, that is rather slow, and produces dense pictures.

For landscape purposes by the Fothergill process, we find a rather *thin* collodion, not contractile, but made with a powdery kind of pyroxyline, answers best, while for the moist process we prefer it rather thick, *not* too highly iodized, *not* old, nor yet too fresh.

As a rule, we object to the use of iodides and bromides of many different bases, the simpler a formula can be rendered the better. For certain purposes there may be exceptions to this rule. We have a good opinion of the suggestions thrown out by Mr. Heisch, relative to the use of bromides and iodides in something approximating to atomic

proportion, and recommend you to read his paper in our last volume, pages 136 to 138.

For a good general collodion that keeps well, we give a recipe, but bear in mind that we cannot have the *best* for *all* purposes in one article.

Make your pyroxyline from the *best cotton wool* with nitrate of potash and sulphuric acid, as directed by Mr. Hardwich, wash well, and to the last water used for the purpose *add a little liquid ammonia*, just enough to give a scent to it. Test your ether for acidity, and if acid reject it. Then take—

Pure washed ether .... 4 drachms.
Pyroxyline.. 8 grains.

Immerse and shake well, allow to stand a short time, then add—

Alcohol (strength 95 per cent.) .... 4 drachms.

Again shake up, when the pyroxyline ought to dissolve.

It is better to make at least half a pound of collodion at a time, though if your consumption is large, a Winchester quart is not too much, and place it in a tall bottle; allow it to rest perfectly untouched for a day or two to let any undissolved particles of cotton subside, then pour off carefully all but the lower portion that remains thick.

The iodizing solution may be made as follows:—

Alcohol, as before.. 4 drachms.
Ether, as before.. 4 „
Iodide of cadmium ....16 grains.
Bromide of cadmium .... 6 „

Add one part of the above to three of plain collodion.

With regard to the honey process, we have been working, and are still continuing some experiments, which promise considerable advantages in manipulation, &c., for we find that for certain purposes it is far the pleasantest mode of operating in our opinion. We expect to be able to publish the results shortly.—Ed.]

DISORDERED NITRATE BATH.

To the Editor.

Sir,—According to your advice, when my silver negative bath became acid, and gave me indifferent and foggy pictures, I added some oxide of silver, and exhibited it to the direct rays of the sun: at first it reddened, and afterwards turned black, without making any precipitate. As this bath is almost new, having been prepared, with nitrate of silver at five shillings per ounce, not longer than three weeks, may I seek your advice in asking if I may decolorise it by adding some kaolin.—Yours, &c.

C. C. D.

[There must be some mistake in your diagnosis, as the medical men would say. Acid baths give weak but not usually *foggy* pictures. Again, darkening in the sunshine without deposit indicates rather *organic* impurity. Try the addition of a few drops of citric acid in solution so long as any precipitate is thrown down, let it settle, and pour off clear, filtering the remainder, then add a few drops of carbonate of soda solution to remove the acidity, and your baths ought to work properly.—Ed.]

IRON PRINTING.

To the Editor.

Sir,—Having tried Mr. Hannaford's iron process twice, and failed both times, I am at a loss how to proceed, in order to obtain a good picture. Will you kindly try to help me out of the difficulty through the medium of your valuable Journal?

I noticed Professor Archer's remark on manganese in your last, and tried paper prepared with boracic acid, sulphide of ammonium, and sulphate of manganese (an original thought), but without effect. Do you think permanganate of potassa will do?

Thanking you for your last, I am, yours, &c.

Liverpool, March 14, 1859. A YOUNG BEGINNER.

[Although we have seen some of Mr. Hannaford's proofs that give indications of *promise*, as also some of Mr. Burnett's and Mr. M'Craw's, none are to us quite satisfactory as yet. The contrast of light and shade is too marked, all the more delicate gradations being either absent, or else the deep shadows are grey instead of black. The chief difficulty appears to be in keeping the lights clean; salts of iron once *in* the paper are very difficult to remove. We think the use of an English paper, well sized with gelatine, and then albumenised, the best to operate upon. Harrison's paper is of this character, and fairly smooth. Be careful not to *over* expose your proofs. We have not much hope of any good result with manganese as a photographic agent in any form.—Ed.]

CARBON PRINTING—FAULTY TONING.

To the Editor.

Sir,—As your correspondent from Swansea wishes to know if any one has got a prize in "the Pouncy lottery," I wish to inform him that not only myself, but many others, have succeeded in obtaining proofs quite equal, and in many cases superior, to those exhibited by Mr. Pouncy, through the information he gave to his subscribers.

Now, in reference to the "*blanks*" sometimes obtained in all lotteries, I think (in fact, I am quite certain) that a great number, if *not all*, obtained *blanks* who sent the *fee* for a recipe for a "toning bath," advertised some few months ago in the Photographic Journals, as superseding all others, for quality of tone, purity of the whites, and above all, economy. I for one got "a blank," as did many others with whom I am acquainted; therefore, I do not think your correspondent is justified in drawing attention to his so-called Pouncy lottery in the "blank" manner he does, seeing that there are other lotteries containing *nothing but blanks*.

In conclusion, I will state that I mixed seven "toning baths" for myself in succession, after trying each one thoroughly, but not a single passable print have I obtained—nay, the whites were even dirtier than "old hypo" is accustomed to give, and not occasioned through any mismanagement on my part in the preparation of the baths, for I have now practised photography in all its branches for the last six years, and have succeeded with every process but the said toning bath.

Perhaps some one will be kind enough to inform the unfortunate subscribers how it is they get such miserable "blank" results,

And oblige, yours truly,

Liverpool, March 22, 1859. MANY BLANKS.

ANSWERS TO CORRESPONDENTS.

Thames Darrell.—See answer to In-quest.

Peter, Tyro, M. T.—See reply to A Young Beginner. No fixing agent but water necessary.

James Southwell, B. M.—We will give you the information desired upon the working qualities of the orthographic lenses in an early number.

Caustic.—No! Take the 10 × 8. You may say who sent you. We leave the selection to him.

R. Dart, Churston-Ferrers.—The term "xylographic artist" could not be properly applied to a photographer, it indicates rather a wood engraver, or one who draws upon wood for the engraver.

X. Peterborough.—See preceding reply. We do not mind stating facts upon such a point, but cannot recommend any particular maker. If you cannot judge for yourself, get some experienced friend to help you.

J. R.—Your explanation is not clear. How much iodide of potassium did you add? Are you sure that your bath was acid before adding carbonate of soda? And lastly, what quantity of nitric acid did you subsequently employ? You may have over-dosed it with one or all of these ingredients, and if you have too much of the last, as we suspect is the case, of course it will not act. See answer to C. C. D.

Thomas Smith, Barmecide, Old Hypo, C. B., F. J. K., and Simon.—You will find answers to all your queries in the numbers of the *present volume*. We have no objection to reply in detail at any time, and always disregard the trouble it may be to us personally to assist our subscribers in their photographic dilemmas; but if we were perpetually repeating such simple matters, we should be open to complaints from the generality of our readers. Surely you cannot have read the last few numbers as well as purchased them.

J. Roberts.—We have tried the formula given by Mr. Maxwell Lyte, and found it, as we expected to do, exceedingly good. You must be careful to have your chloride of gold *neutral*, and in order to do so you will require to add solution of carbonate of soda until all effervescence ceases, and litmus paper is not rendered red when immersed in the solution. When neutral, add sufficient water to make up such quantity as a total that will make the solution contain eight grains of chloride to the ounce, each drachm by measure then would contain one grain. The proofs should be well freed from *nitrate of silver* before immersion in the toning bath, and if one hour does not do, give two or ten if need be, being careful, however, to protect it from *strong light*.

J. McM.—If you have but one dark frame for plates, nine by seven inches, you will find the following plan for changing them in the field answer well:—The plate-box in which they are carried must have a provision for excluding light at the lid junction. Take two thicknesses of yellow calico (or better still, yellow tammy) and make a bag of the whole width of the stuff, with a mouth capacious enough to go on the end of the camera. The mouth is to be furnished with a piece of elastic band to keep it close. At the lower *angles* of the bag make two openings, large enough to admit the hands, and furnish them also with elastic bands to close round the wrists; lastly, insert about the centre of one of the sides of the bag two pieces of yellow glass (like spectacle eyes), and sew a piece of elastic across in such a manner that if passed over the back of the head, it will keep the glasses in contact with the eyes so as to look through. To operate, put the plate-box into the camera with the lid towards you, and the glasses with the collodion side upwards (to prevent rubbing off the film at the edges in drawing them out), the dark frame in the bag, which latter is then to be slipped over the open end of the camera. Look through the glasses, put the hands through their opening, and the manipulation is very easy—the elastic round the head keeping the bag extended.

Received: Letter from our New York Correspondent (which shall appear in next publication)—and "An Old Subscriber." Had the latter complied with the request to forward letters on *editorial* matters to the address indicated below, instead of to Liverpool, an answer to his query would have been in time for this number.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal, *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE PHOTOGRAPHIC JOURNAL.

No. 92, Vol. VI.—APRIL 15, 1859.

It was with much pleasure that we recently made the personal acquaintance of M. Voigtlander, the celebrated optician, of Vienna, whose name is well known to most photographers in connection with the construction of photographic lenses in general, and orthoscopic ones in particular. In the course of conversation with this gentleman, we were informed by him that *every lens* which leaves his establishment is not only carefully examined by himself, but that he personally invariably gives the last finishing strokes to them all, as he graphically expressed it, "with his own ten fingers." This it must be admitted is the best guarantee for an approximation to uniformity of excellence.

We were invited to attend at M. Claudet's gallery in Regent Street, to assist at a comparison that was made between lenses the production of MM. Voigtlander and Dietzler respectively (the last-named being the optician at present working under the guidance of Professor Petzval), but important business engagements prevented the possibility of our being present. A contemporary has however published a statement of the facts and conclusions arrived at, which agrees in all particulars with what was related to us by a gentleman present at the recorded examition, as well as with Mr. Kater's account, which will be found in the report of the London meeting.

We do not express any opinion upon the respective merits of the lenses compared, not only because we have never personally compared them one against the other, although we have examined *each* kind *separately*, but because also we contend that the mode of investigation adopted was not a proper test of the capabilities of various *photographic* combinations of lenses—the visible images only having been criticised without any proofs having been actually taken. Now we assert most positively that we have found lenses giving brilliant visual images and yet very indifferent photographic ones; whilst others have produced pictures decidedly better than their visual images would lead an observer primarily to expect. We admit that a lens producing the best photographic impression will generally be found to produce also a good visual one, but the converse of this proposition by no means holds good.

We are informed that the mode of testing adopted was that insisted on as most satisfactory by Professor Petzval himself; we do not however so understand that gentleman's assertion, but merely believe him to declare that, in examining photographic lenses when made by a special formula, it is not necessary to take a picture with each one of them to become satisfied of its adaptability to the purpose intended, and to this proposition we yield assent; but if it be contended that an optical examination of *any* lens is sufficient to decide its photographic qualities, we must, notwithstanding an authority so weighty on the other side, express our emphatic dissent.

There is another point upon which we have a word of objection to record; it is this, that in noticing the amount of *curvature of field*, especially in a landscape lens, the image as seen by the eye is by no means a criterion to be relied on. Of this fact we are strongly convinced by practical experience, and knowing it to be as we state, we seek for an explanation of the phenomenon, which we take to be as follows:—In a landscape lens, owing to the diaphragm being placed at a distance from the glass, different portions of the lens are employed to produce the centre and edges of the picture; now if the visual and actinic foci are made to co-incide for centrical axial pencils of light, they ought not exactly to agree for lateral oblique pencils, for near the circumference of the lens the crown glass is thinnest and the flint glass (that possessing most dispersive power) is thickest, hence the effect produced is what opticians call over-correction, consequently the tendency is to throw the chemical focus further from the lens in *that part of the subject* than the visual one, hence that which at first appears to be a defect becomes available as a positive advantage.

We do not, then, undervalue an examination of the visual image in its way, but do contend, that for photographic purposes that is only a part, not to say a small part, of the work required to be done to arrive at a just conclusion.

We have been favoured by Messrs. Murray and Heath, of Piccadilly, with a copy of the likenesses of the Imperial Commissioners Kweiliang and Hwashana, who signed the recent treaty entered into between our own Sovereign and the Chinese Emperor. They are in their native costume, of course, which to an European eye presents any thing but a graceful appearance, and while the first-named is in a constrained attitude, with decidedly angular outlines, the other seems more at ease. They are seated, one on each side of a table adorned (?) with drapery, having figures peculiar to the Chinese upon it, and on the table are two glass jars, the jars, instead of the heads, being crowned with the conical mandarin hats "with the little round button at the top."

As an interesting historical record, the photograph will no doubt be valued. It was taken on the 1st July, 1858, at Tien-tsin by Mr. Robert Morrison, attaché to H. B. M. Mission in China. Unfortunately, the negative became injured during the voyage to this country, hence it was necessary to call in the aid of an artist to render it a presentable picture, but the characteristic features of the Commissioners are preserved.

While in conversation the other evening with Mr. P. W. Fry, one of our oldest and ablest photographers, and who was amongst the first, if not the first amateur experimentalist with collodion, that gentleman mentioned the fact, that for very many years he had been in the habit of employing a partially air-tight box for the preservation of sensitised sheets of chloride paper. The kind of box used by him, was one of those cylindrical red leather boxes, made for carrying writing materials, the cover sliding on and fitting very closely, so closely, that on opening the box, a tolerably loud report is made from the compression of the air.

It is somewhat singular as well as satisfactory, that a proceeding, found to be practically effective so many years ago, should now be recommended upon purely theoretical grounds; and if M. Gaumé's arrangement of inserting super-dried tablets of plaster of paris should be found by experience to be successful, it would appear that a very simple piece of apparatus, adapted to the wants of amateurs, may be readily acquired, by casting a

plaster cylinder in a mould made by a ruler, drying it in the oven, and wrapping sensitive paper around it previously to inserting it in such a box as we have been describing. This would probably preserve the paper for from a week to ten days, with little or no trouble, and would therefore be sufficient for most occasions.

We have much pleasure in noticing that many of those employing albumen in the dry collodion processes as a substratum for the film, are calling to mind the fact that to Mr. Barnes is due the credit of having originally suggested its use in this way; and though several others have independently arrived at a similar conclusion as to its advantage, it is a fact which in no way detracts from the value of their observations, while at the same time it is a kind of tribute to Mr. Barnes's acuteness.

We regret to find that Mr. Moon, the able honorary secretary of the North London Photographic Association, has been obliged, from the state of his health, to resign his post to Mr. Barnett. The committee, as will be seen in another column, accorded an expression of their appreciation of his services. We trust that the compliment also paid to ourself may be as well merited.

We are much gratified in being able to announce the formation of a Photographic Society at Leicester, a fact upon which we heartily congratulate the inhabitants of the district, as we know of few pursuits more conducive to the amusement and instruction, not only of its immediate votaries but also of those connected with them. Photographic Societies, when properly conducted, not only form centres of union for those engaged in kindred pursuits, but also tend materially to promote agreeable social gatherings, at which many delightful and lasting friendships are frequently formed, events which would not in all probability otherwise have occurred.

In the foreign correspondence will be found a communication from our United States informant, which almost makes us think that the designation *United* is somewhat Hibernian, and were the letter not written by an American, we should have come to the conclusion that the writer was misinformed upon some of the matters of which he treats.

To those who are still investigating the practicability of the substitution of iron for silver printing, we commend an attentive perusal of some remarks made by Mr. Johnstone, at the last meeting of the Birmingham Photographic Society, which will be found at p. 97, and trust that they will carry out the suggestions there thrown out.

SILVER PRINTING PROCESSES,

Including Salting, Sensitising, Toning, Fixing, and Testing Baths.

By C. J. Burnett.

A.

SALTING BATHS.

Proportions of Salts for an 8–10 *ounce Bath.*

No. 1.

80 grains chloride of ammonium.
30 „ bromide of potassium.*

Paper so salted may be sensitised with plain nitrate bath, but is rather intended for ammonio-nitrate, and *more especially* for the modifications of baths (to be presently described), consisting of ammonio-nitrate with the addition of citric, benzoic, or other acids, sensitised with which it gives admirable results.

No. 2.

70 grains chloride of ammonium.
25 „ bromide of potassium.
40 „ benzoate of soda.

This paper prints very rapidly, and gives good tone when sensitised with plain *neutral* nitrate of silver bath, but may also be sensitised, if wished, with the other baths. (Try it with No. 10.)

* Bromide of cadmium or of ammonium may be substituted in equivalent proportions here and elsewhere, and may sometimes have the advantage over it.

Nos. 3, 4, 5, 6, 7.

Same as 2, but with (3) citrate, (4) tartrate, (5) oxalate, (6) *succinate*,* in something like the equivalent proportions, or (7) formiate, instead of the benzoate of soda.

With citrate of soda or tartrate of ammonia† we get good tone, but with rather inferior sensitiveness to No. 2; however, the paper keeps better after sensitising than that salted with No. 2.

No. 8.

90 grains chloride of ammonium.
50 „ benzoate of soda.

A good and rapid paper, when sensitised by plain nitrate of silver bath, has the advantage over paper salted with mixtures containing bromides of being fixable by ammonia, which the latter are not.

Nos. 9, 10, 11, 12, 13, 14, 15, 16, 17.

Same as 8, but with a (9) citrate, (10) tartrate, (11) oxalate, (12) racemate, (13) succinate, (14) fumarate, (15) formiate, (16) meconate,‡ or (17) carbonate, substituted for the benzoate. With the exception of No. 16, they are also all suited for use with ammonio-nitrate baths and ammonia fixing.

N.B.—These same mixtures of salts may be also all used in the preparation of albumenised paper (either in the proportions named, or with a larger proportion of the *citrate* or other vegetable salt), and with very great improvement in the tone generally given by albumenised papers.

B.

SENSITISING BATHS.

No. 1.

Citric-ammonio-nitrate bath being a common ammonio-nitrate bath (say 60–70 grains to the ounce) as ordinarily prepared, with the addition of citric acid, either as citrate of ammonia; or else in the pure form, in a saturated solution, to as great an extent as can be done without producing a permanently insoluble precipitate,§ shaking well.

No. 2.

Benzoic-ammonio-nitrate bath. Same as No. 1, but with the substitution of benzoic acid or benzoate for citric acid or a citrate. Benzoic acid being sparingly soluble in *cold* water, must be introduced, either as a solution in *hot* water or in the dry, flaky crystals in which it is sold. I have got a capital bath by adding them in pretty considerable quantity, and after shaking them up well and leaving them in the liquid for a day or two, then filtering the bath from what of them remained undissolved; but a less quantity added will also give a very good bath, *e.g.*, we may saturate one-half of the ammonio-nitrate bath and then mix it with the rest. I am not sure that the papers prepared by this bath keep quite so well as those by bath 1; however, they seem still more sensitive. I find a bath neutralised partly with citric, partly with benzoic acid, give capital prints.

Nos. 3, 4, 5, 6, 7, 8, 9.

Same as Nos. 1 or 2, but with (3) succinic, (4) malic, (5) tartaric, (6) oxalic, (7) formic, (8) carbonic,‖ (9) acetic acid, or one of their salts, instead of the additions in 1 or 2.

The sensitising baths now described, especially as prepared by the addition of the free *citric*, benzoic, tartaric, succinic, or other acid, have great advantage over the ordinary ammonio-nitrate baths, whether used with chloro-bromide paper (formula 1) or with the ordinary chloride-salted papers (Marion, Canson, Rive, Pirie, Saxe, or others), with both of which they give most admirable results, both as to tone and as to rapidity of printing, as well as *what is most important of all*, the adequate representation of all the delicacies and half-tones of the negative printed from. With these baths I have also been in the habit of floating both the chloro-bromide and the chloride papers, without finding any tendency to deterioration of the bath, or at all events any which cannot be remedied by the occasional addition of a little more nitrate of silver, and it may be, a little more citric or other acid.

(To be continued.)

* The idea of the succinate we owe, in the first instance, to Mr. Hunt's "energiatype" process.

† Tartrate of ammonia is what I used in my experiments in 1854-5, and is easily made, but common Rochelle salts will also answer.

‡ The meconate must be pure and made from acid which has not been browned by alkali in its preparation, and is best used in an acid bath, or in preparation of paper to be used for an acidulated sensitising bath, or acidulated sensitising solution to be applied with "Buckle's brush." N.B.—Gallic and pyrogallic acids should also have a fair trial here instead of the meconates.

§ Or saturate one-half with citric acid and then mix with the rest, in the same way as Mr. Hardwich recommends, in his new edition, with nitric acid.

‖ By passing carbonic acid gas through the solution in a deep bottle from a bent tube connected with another bottle containing chalk and muriatic acid.

ON MICRO-PHOTOGRAPHY.

By Joseph Sidebotham.

[Read at the Meeting of the Manchester Photographic Society, April 6, 1859.]

Several paragraphs having lately appeared in the public papers, with reference to the production of micro-photographs, one or two persons having claimed, as a new discovery, what has been known and practised a long time; I think it merely an act of justice to my friend, Mr. Dancer, to place on record what share he has had in originating these beautiful productions.

Mr. Dancer, if not actually the first, was *one of the first* who took a daguerreotype picture in this country, before any specimens taken by Daguerre himself had been brought over: as early as the year 1839 he paid some attention to the production of minute photographs on silver plates, reducing a bill of twenty inches in length to one-eighth of an inch, by means of an achromatic combination of one-and-a-half inch focus. At the suggestion of a friend, he then used for the purpose the eyes of recently killed animals, and produced with them some minute photographic pictures; these being electrotyped, and several copies taken from each, produced the letters and images of the pictures in their proper position.

In July, 1840, Mr. Dancer publicly exhibited, during a lecture at the Liverpool Mechanics' Institution, the mode of taking photographs of microscopic objects, a flea being magnified by the gas microscope to a size of six inches, and a photographic image of it taken on a silver plate during the progress of the lecture. He also took photographs of sections of wood and fossils, both on paper and on plates, by means of the solar microscope. I may just mention that about this time Mr. Dancer tried experiments with the solar spectrum, and obtained on paper evidences of colour both in the red and yellow rays.

Owing to the nature of the deposit forming the photographic image on silver plates, micro-photographs could not be viewed with a higher power than about twenty diameters, consequently Mr. Dancer laid the matter aside, until Archer's discovery of the collodion process, which at once suggested itself to him as applicable to the production of minute photographs.

I have in my possession two micro-photographs, given to me by Mr. Dancer early in 1853; they are about one-sixteenth of an inch in diameter. One is a copy of the monumental tablet erected to the memory of Sturgeon, the electrician; the other a group of portraits of Mr. Dancer's own family. Since that time Mr. Dancer has paid considerable attention to the subject, and produced much more minute and perfect specimens, copies from pictures and photographs from nature in great variety, and has supplied them to the principal opticians here and on the continent, and there are few interested in such matters who do not possess some of them. The Queen is in possession of a set of portraits of members of the royal family and other subjects, the production of our respected townsman.

As an instance of the extreme minuteness of some of these photographs, I may mention that Sir David Brewster calculated, from a specimen sent to him by Mr. Dancer, that an encyclopœdia of twenty volumes could, if reduced to the same dimensions, be easily carried about in a purse.

I have made the foregoing remarks in order to claim for my friend, Mr. Dancer, some of the credit due to him for his labours in this direction. Having had the pleasure of his intimate acquaintance for nearly twenty years, I am in a position to speak with confidence. Mr. Dancer's modesty will not allow him to speak of his own discoveries, but I am sure you all join in the annoyance I have felt in seeing persons coolly claim as their *own new discoveries* what our respected townsman has accomplished so many years ago.

ON PRINTING GLASS TRANSPARENCIES.

By T. H. Nevill and James Dorrington.

[Read at the Meeting of the Manchester Photographic Society, by Mr. Dorrington.]

This paper, which is contributed by Mr. T. H. Nevill and myself jointly, has no pretensions to being either scientific or chemical; it is intended simply to record the results of a series of experiments made with a view to overcome the various difficulties attendant on the processes by which glass transparencies had previously been printed, and which had been found so tedious, and in the hands of the amateur so frequently uncertain.

The members present who had the opportunity of seeing the various transparencies contributed by gentlemen connected with our Society, and exhibited with the magic lantern, by Mr. Dancer, at our monthly meeting, on the 1st of December last, will recollect how many of them, beautiful as they were in subject, and mostly printed evidently from very good negatives, were defective as pictures, from want of cleanliness and of brilliancy. They were the results of many processes, such as collodio-albumen, Fothergill's, honey, and dry collodion; many of them were also furnished, as they had been manipulated by the most successful of our members, as they doubtless consisted of some of the best pictures which each could bring. But it was very evident, that much was at that time needed, even as respects the obtaining of good pictures at all, to say nothing of the tedious length of time which some of the processes necessitated, whether we regard the first preparation of the plates, or the subsequent developement, and of the numerous failures, after all the care and pains bestowed upon them which the pictures exhibited, evidently indicated, even more than they actually expressed.

It was with a view to obtain some more simple and certain process than any in use that the experiments now about to be detailed were undertaken, and which have at length resulted so satisfactorily in that process which I had the pleasure of communicating to this Society, at its monthly meeting in February last; a process which all the experience which Mr. Nevill and I have had with it subsequently (and we have printed with it, probably, at least two hundred transparencies, with nearly uniform success), has established as particularly suitable for attaining the object we had in view.

Amongst the transparencies exhibited by Mr. Dancer, with the magic lantern, at the meeting of the 1st of December last, were a few which I had printed according to the formula of the Rev. Mr. Sisson, communicated through the columns of *The Times*, on the preceding 18th of November, called the "Raspberry Syrup Process." I had, however, used raspberry vinegar, which, successful at first, I still find superior to the syrup recommended. This, "another new process," was on its first announcement subjected to a perfect storm of ridicule, headed by the grave and sober editors of photographic journals and almanacs, and taken up with fun and frolic by other contributors, down to Job Trotter's merry friend, "J. M.," the famous discoverer of the celebrated "gin and water process," who, as gathered from his very clear letter, made no such pretensions to that absolute sobriety of body or mind, which doubtless always characterises the editorial body, when, *ex cathedra*, they fulminate their infallible decisions. With due reverence to them, and equally due respect to their august dicta, I felt, unfortunately, that I could not accept their judgment upon a process which evidently they had judged before trial, and which in my hands was yielding excellent results, say brilliancy, depth of shadows, and unfailing cleanliness.

Defects and Proposed Remedies.

But there was one drawback to it, and that a very serious one, viz., that the films were very loose, and consequently very difficult to retain on the plate. To overcome this, Mr. Nevill suggested the use of a little albumen round the edges of the plate. By this means the film was readily enough kept on, but it remained doubtful whether the amount of washing which the printed transparencies would bear after fixing, and which washing required to be manipulated with great delicacy, was sufficient to ensure its permanency. The experiments thus far carried on, were detailed by me at our meeting on the 1st December last, and led to a general conversation on the subject, when several suggestions were made, none of which, however, struck us as superior to the plan we had adopted of albumenising the edges of the plates.

Mr. Nevill, however, was not satisfied with the process on account of this serious drawback, considering that a film so loose as to be in danger of washing off the plate would necessarily be open to objection, and he commenced an extensive series of experiments, having as their object to replace the raspberry syrup with some other preservative, which would afford equally effective results, but free from the objectionable looseness of film. Amongst the various substances which he employed in these experiments were isinglass, serum of milk, sugar of milk, grape sugar, and gum: these he dissolved in water, and with spirits of wine, in various combinations. He also tried spirits of wine alone as a preservative. The general result was, that whilst many of these substances gave very fair results in respect to the pictures produced, they were mostly as loose in the film, and not equal in brilliancy or in intensity, as those obtained by means of the raspberry syrup. The only process which in his hands rendered the film perfectly adherent was one tried with serum of milk, which had been prepared with treacle, much in fact in the style of a treacle posset. The collodion film thus covered would bear any amount of washing, but the surface of the plate was so greasy as to render an even developement next to impossible.

After this point, Mr. Nevill's experiments took a new direction, in consequence of his reading a paper by Mr. George Nevile, which appeared in the *Journal of the Photographic Society*, of the 21st Dec.

ast, in which it was suggested to cover the plate with a thin film of albumen prior to applying the collodion. This suggestion was entirely new to Mr. Nevill, who, whilst carrying on his subsequent experiments, believed it to be original. It was, however, only the following out of a very old suggestion, as subsequently has turned out to be the case —for, so far back as the year 1854, the same plan was suggested by the Rev. William Law, rector of Marston, in a letter published on the 21st Oct., 1854, in the same Journal. And again, a similar recommendation is to be found in Mr. T. Barnes's small work on the "Dry Collodion Process," published in 1856.

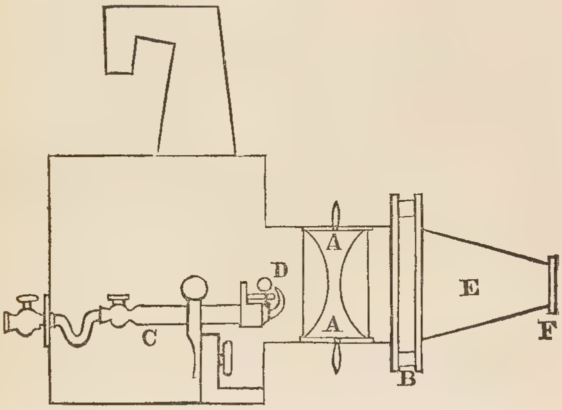
(To be continued.)

DESCRIPTION OF A LANTERN FOR MAGNIFYING PHOTOGRAPHIC TRANSPARENT POSITIVES, FOR THE ILLUSTRATION OF LECTURES, &c.

By W. Hislop.

[Read at the Meeting of the North London Photographic Association, March 30, 1859.

The lantern is of wood and of the usual form.



The condensers are two plano-convex lenses, each of four inches in diameter and six inches focus. These are set in a cell (A), with their convex surfaces towards each other: this cell is capable of being slid to and from the light or object, for the purpose of adjusting the illumination.

B is the aperture for the admission of the slide, and in front of this is a cone (E), at the end of which (F) is screwed a quarter or one-sixth portrait combination.

The lime light is preferred for illumination. The arrangement consists of a Flemming's safety jet (C), placed longitudinally, so that it can be moved to and fro. On the barrel of the jet is a clip, having a stud attached to it, on which a ball of lime is placed, and adjusted so as to receive the stream of gas from the jet D. A stopcock is screwed to the outside of the lantern (which I prefer to be of wood), and is connected inside with the jet by means of a piece of india-rubber tubing. The gas used is composed of equal volumes of coal gas and oxygen, and the light produced is exceedingly brilliant.

I find that the use of the portrait lens as a magnifier gives such excellent results in definition, and freedom from colour, as to render it possible to use the ordinary gas-microscope objects, which are thus shown with far more distinctness than the low magnifying power used would lead us to expect.

With ordinary slides, or for coarse pictures, a common argand oil lamp may be employed with excellent effect.

The diagrams exhibited consisted of the moon and other astronomical subjects, Arachnidæ, vegetable cuticles and their appendages, from microscopy, horological subjects, maps, and some few views.

The adaptability of the arrangement for the larger class of microscopic objects, such as sections, algæ, trachæ of caterpillars, and whole insects, was also shown.

NOTICE OF RECENTLY PUBLISHED STEREOGRAPHS.

Amongst the most pleasing of our editorial duties we may reckon that of awarding commendation which has been faithfully earned. There is, perhaps, no branch of photographic industry which is so extensively pursued as the production of stereographs — a remark that holds good, not only as regards the negatives, but also in respect to the number of positive proofs printed therefrom.

Wherever our wanderings may be directed — in shops devoted to all sorts of manufactures, as, for instance, in those of opticians, stationers, chemists, fancy warehousemen, dealers in china and glass, toys, &c.—we find displayed in the windows stereoscopes and the accompanying slides.

Where quantity is in such profusion, quality is too often lost sight of; and though the effect of apparent solidity is of itself sufficient to charm the novice in stereoscopic matters, without reference to the nature of the subject delineated, such is not the case after the surprise of novelty has worn off.

There are, however, but few persons who have made much use of the stereoscope who would be willing to forego the possession of the instrument, if provided with slides of an interesting character; and no matter how many they may possess, they are constantly adding to their stock, not because they weary of those they have, but because the inspection of a well-executed subject in the stereoscope is but little short of an actual visit to the place itself, and thus with every addition the pleasure of a new experience is acquired.

We have just received from Mr. W. Woodward, of Chapel Bar, Nottingham, a series of admirably-executed stereographs, chiefly of architectural and rural subjects, that are deserving of the highest commendation, and as photographs possess very considerable merit, not on account of their execution, but also as regards artistic excellence. Some of the subjects we have seen before, and had occasion to notice favourably when awarding the prizes given by the Nottingham Photographic Society.

We have, on the occasion just quoted, already remarked upon the slide of *Peterborough Cathedral*, which is taken from the north-east corner of the Minster Yard, and gives an excellent notion of the building. We recommend Mr. Woodward to take another view of the same Cathedral from the Market Place, a position which commands the beautiful west front, and, if executed with his usual skill, we can venture to promise him a tolerably extensive sale of his proofs.

Two slides of *Woollaton Hall*, the residence of Lord Middleton, are also valuable illustrations of architectural subjects; that with the tree in the foreground being particularly interesting to all lovers of the picturesque, though architects will probably prefer the other view of the building, designed by the celebrated John of Padua, on account of the details being none of them intercepted by intervening objects.

Newstead Abbey, *The Menai Bridge*, and *Conway Castle*, are also interesting productions of a similar class. The first-named, we fancy, would have been more picturesque if taken from a position a little further to the right hand than that chosen, but we notice that it would then have required a later hour in the day to have rendered the shadows as effective. In the *Menai Bridge* view, the wooded scenery on the opposite side of the water is distinct, yet properly subdued; there is detail without undue obtrusiveness, a quality, we were dogmatically informed by an artist a few years back, that a photograph *never* could possess.

Of the *View in Wilford* (No. 24), the prize picture, we have already given detailed particulars in Vol. VI. No. 86, page 24; there are, however, three others from the same village, which possess nearly an equal degree of merit. These are charming bits of English rural scenery, that are truly samples of our homely landscape beauties, consisting of thatched cottages, half buried in foliage, the pleasant shade under which forms a refreshing contrast to the flood of sunlight bathing the rest of the subject. In one, a wreath of half-transparent smoke curls gracefully against a background formed by masses of leaves; in another, a fine old walnut tree completely overwhelms a little cottage under its protection; in a third, a horse-chestnut tree shelters a truly rustic home. The slides to which we allude are numbered respectively 4, 7, and 29.

The Bridge in Burghley Park is, perhaps, one of the best-executed and happily-selected in the collection. The beautiful transparency of the tranquil water, bearing on its surface the floating leaves of the water-lily, the reed-bordered bank of the stream, the bridge half screened by the shrubs, and wholly reflected in the crystal stream, produce altogether a composition as delightful as it is placid.

We cannot conclude without the mention of one more amongst Mr. Woodward's collection — that of a *Valley in North Wales*, near Llanrwyst, that is pleasingly illustrative of mountainous scenery.

By a careful examination of the pictures we have been describing, we have come to the conclusion, that Mr. Woodward operates with one lens, and exposes his plates necessarily at two separate consecutive spaces of time. Now, as a matter of economy in apparatus, this is all very well, and for taking positives on glass for stereoscopic subjects, it is decidedly the best plan, as the two

impressions can be taken in the correct relative position without transposition—a necessity that would involve, in this case, the cutting in two of the slide; but where *negatives* are the desiderata, this position is not of any consequence, because the paper proofs can be transposed, and the advantage of taking the two pictures simultaneously is not to be lightly disregarded. Not only is a portion of the effect sacrificed by a slight shifting of the shadows when the impressions are received consecutively, but it frequently happens that owing to a variation in the light, one picture gets more done than the other, although perhaps equally exposed, and in some cases the loss of the sharp shadows in one, and not in the other, is the inevitable consequence of a troublesome cloud intervening between the times of the two exposures. We think, therefore, that so skilful an operator as Mr. Woodward has proved himself to be, does not do himself justice in employing a single lens camera, for, however great an adept a photographer may be, he does not act wisely in neglecting any advantage whatever, of which he might avail himself if he would. If Mr. Woodward will adopt the use of a bi-lens camera, he will, we doubt not, earn fresher laurels —but in offering this suggestion, we would have it understood that it is not from any noticeable deficiency in his productions that we make it: rather because he works so well that we would fain relieve him of unnecessary difficulty.

We may remark, for the encouragement of those employing dry processes, that Mr. Woodward's pictures, abounding in detail, brilliancy, and half-tone in perfection, are all taken by the collodio-albumen process.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

An ordinary general meeting of the above Society was held on Tuesday, the 5th instant; Professor Vignoles in the chair.

The minutes of the last meeting were read and confirmed, and several gentlemen were duly elected members of the Society.

Messrs. Burfield & Rouch exhibited a new folding camera, of ingenious construction; also a modification of their dark operating chamber, by which it was converted into a roomy and commodious dark tent for working large collodion plates in the open air.

Mr. Sutton, of Jersey, exhibited a model of a boat built for photographic purposes, and the Secretary read a description of it. The two ends of the vessel were made alike, that is, with bows at either end, the length being about forty feet. The bottom of the boat was flat, and furnished with a false keel, to give stability, but which could be readily unshipped to adapt the vessel for shallow water. The timbers were merely uprights attached to the bottom, thus avoiding the use of curved timbers, by which the cost of construction would be materially less than would otherwise be the case. A small cabin and three masts were provided, and the estimated cost of the whole amounted to but £50.

The Chairman said, that speaking from his own experience, having been in many parts of the world, he considered that travelling by boat was a very pleasant mode of conveyance, to say nothing of the convenience of carrying photographic apparatus in that way.

The Secretary then read the names of those gentlemen who had been appointed by the council a sub-committee to examine and report upon Mr. Hardwich's collodion, as requested by that gentleman at the previous meeting of the Society. The committee was to consist of Messrs. Fenton, White, Mayall, Williams, Llewellyn, De la Motte, Bedford, Rosling, Frith, Hughes, Morgan, and Robinson.

Mr. Malone suggested the addition to the collodion committee of Mr. Storey Maskelyne, who was one of the first to draw attention to the probable importance of the addition of bromides with iodides; of Mr. Hughes, of Middlesex Hospital, who has devoted great attention to matters of the kind; and of Mr. Spiller, whose labours in connection with this subject were well known; and there would then be three chemists upon the committee.

Mr. Hardwich, so far as he was concerned, assented to the addition, stating his belief that the addition would give satisfaction, and that in proportion to the number of names upon the committee.

The Chairman stated that, inasmuch as it was for the advantage of the Society and for the art of photography, there should be as much light of science thrown upon the subject as possible: if the three gentlemen named did not object their names would no doubt be added by the council; and this would have been the case, without the subject having been brought before the meeting, if Mr. Malone had been good enough to have communicated with the council upon the subject.

Mr. Le Neve Foster objected that the meeting was proceeding irregularly. The council was very desirous of falling in with the views of the Society at large; yet still it was the duty of the council, and not of a meeting of the Society (unless specially convened for the purpose), to appoint a committee.

Mr. Malone suggested, that if the names were not added there would ensue the anomaly of a chemical report from other than chemists; and was proceeding to move accordingly, but was stopped by the Chairman, stating that it was unnecessary to make a substantive motion, as he was sure the council would attend to the suggestion.

The Chairman announced the presence of M. Voigtlander, and hoped that gentleman intended to impart to the meeting some of the knowledge which had made his name so celebrated throughout Europe.

M. Voigtlander simply responded by a bow.

Mr. Roger Fenton asked to be allowed to show some copies of pictures taken by Mr. Thurston Thompson (by means of a Ross's lens, constructed upon the principle recommended by Professor Petzval), which were all that could be desired, but stated that there was a gentleman present who was better able to speak of them.*

The Secretary then read a letter from Mr. Kater, dated 46, Sussex Gardens, March 6, 1859, relative to the comparison of lenses, the manufacture respectively of MM. Dietzler and Voigtlander, of Vienna.

He stated that, having attended at M. Claudet's gallery, by invitation, to witness a trial of quality between the lenses above indicated, two sheets of *The Times* newspaper, in every respect corresponding with each other, were pasted upon a screen; the lenses attached to similar cameras being covered up so as to prevent the possibility of noticing the maker's name of either, but being indicated by the letters A and B, were examined as to the images formed by each upon the ground glass screens. This was done repeatedly, and in every instance the same lens was found to produce the most brilliant and sharpest image. On uncovering the lenses, the one pronounced the best was found to be that manufactured by M. Voigtlander. On removing the posterior combination from M. Dietzler's lens, and substituting the corresponding part of M. Voigtlander's, the performance of the former was found to be improved, but still somewhat inferior to M. Voigtlander's lens entire.

A similar proceeding was then adopted with the "orthoscopic" arrangement of each maker, with similar results; and in addition the flatness of field was ascertained to be considerably in favour of M. Voigtlander's lens.

Moreover, the mechanical arrangements for facilitating the adaptation of the front lens of the portrait combination, to form it into the "orthoscopic" lens, were far more convenient in M. Voigtlander's than in M. Dietzler's production.

No pictures were taken, a simple examination on the ground glass screen being alone adapted.

The Chairman intimated that the letter was read as expressing the opinion of the writer, but not of the Society, and hoped the meeting would have the advantage of observations from Mr. Voigtlander and others.

The subject of lenses was one upon which great difference of opinion might arise, not simply from the circumstance of what astronomers called the personal equation (the mode of observing), but also from the extreme difficulty of making lenses all perfectly alike, therefore, it would be interesting if any gentleman who had studied the subject would then make remarks that might lead to a discussion upon that which really wanted elucidation.

Mr. Mayall stated that some time since Mr. Joubert did him the honour of lending him one of the Petzval lenses, made by Dietzler. Mr. M. carefully examined it in comparison with another of the same diameter, by Voigtlander, and went very carefully through a series of experiments, first, to ascertain that the curves of the two lenses were the same, because he believed it had been stated that M. Voigtlander had deviated from the formula which Professor Petzval had first given, and that consequently his lenses were not of the quality exhibited to this Society, and upon which a paper was read by Herr Paul Pretsch.

Mr. Mayall found, after very carefully measuring the curves, that there was scarcely any deviation, except that in the last curve there was a very small difference—the one being 17·50, and the other 18; however, in testing them upon *The Times* newspaper, and some other tests of a similar kind (a very excellent one being a lady's dress, with a small check), there was no comparison in point of quality—Voigtlander's lens was very much superior—in fact it was so much so that it had been his (Mr. Mayall's) intention

* These were copies of portions of the Cartoons of Raphael and other works of art, and demonstrated the applicability of the orthographic lens to the purpose of producing faithful transcripts from *flat surfaces*.

to propose an examination by the Society into the qualities of lenses. Other Societies were doing something of the kind—the Photographic Society at Edinburgh had entered into some experiments, and this Society ought not to be behind.

A committee should be established upon precisely the same footing as the committee to examine collodion; there need be no more mystification—every one ought to know what lenses or series of lenses he had better adopt, and this would excite the opticians in future to do something superior. The great quality of a lens, that possessed by Voigtlander's, is shortness of focus—he (Mr. Mayall) could teach a boy in two months to grind a lens of a long focus that would take a good picture, but the difficulty is to make one of a short focus to cover a large field; by shortness of focus one gets an increased amount of light, and if you reduce the aperture so that the area through which the light passes shall be equivalent to that in a long focus lens, we get that which is technically termed fore-depth.

He would suggest the formation of a committee, consisting of Mr. Malone as one, that gentleman's practical experience having been very considerable; Mr. Claudet as another, though he (Mr. Mayall) did not know whether he was a member; but there was Mr. Shadbolt, and one or two other gentlemen, who would form a nucleus, and they might have power to add to their number.

Give to each optician notice that he should send to the committee his very best production, of a given diameter; then let the committee select promiscuously from each maker's lenses another one, so as to be able to test that which each maker professes to be his very best, and that which he ordinarily delivers to the public: by that means we should enable a photographer, with abilities of no great calibre, to select his lenses (which it must be remembered are none of them perfect, every one having a series of errors balanced so as to give the maximum results). This object could only be obtained by a number of gentlemen examining and comparing them, and giving a report which the Society would adopt.

Six years ago, when meetings of this Society were held at the rooms of the Society of Arts, he had made the same observations: he (Mr. M.) felt that any one choosing to advertise in the Journal of the Society should advertise on the *outside* sheet and not in the interior. It was high time that a scientific journal should put down such a system; for the future the scalping knife should be used in relation to many of the papers read.

As we know that this house, like another house, is about to disperse, and, as summer time is coming, we shall be out at different places collecting the beauties of nature, we ought therefore to have one or two lenses that we know are the best of their kind. He hoped he had said nothing which might appear invidious to any gentleman; if he had, he begged to apologise. He simply desired a committee to inquire which may be the best lens procurable—whether it be Ross's, Voigtlander's, Shepherd's, or anybody's—and therefore moved, that a committee be formed, naming Mr. Malone, Mr. Shadbolt, and any other name which might suggest itself, with power to add to their number.

The CHAIRMAN believed that such a course of proceeding would be quite contrary to the practice of all scientific bodies in London, and probably of Europe. As a body, except under particular circumstances, societies do not engage to pronounce opinions upon matters such as Mr. Mayall had suggested. That it was extremely desirable and for the advancement of science that such a committee should be appointed, might possibly be true; but if it were adopted with a view to extracting an opinion from the Photographic Society, that this or that maker's lens is the best, it would be contrary to the principles of regular scientific societies. There could be no doubt that an opinion from a committee of gentlemen would be very valuable; yet there appeared to be doubt whether the question of the formation of such committee ought to rest solely with the council, or to be delegated to the Society. He called on Mr. Fenton, as more experienced in presiding over the Photographic Society, for his opinion upon this point.

Mr. MAYALL said that he could obviate all difficulty by simply withdrawing names and proposing a committee.

Mr. ROGER FENTON felt that he had been enjoying the *otium* of a private station during the evening, and had been relieved from the cares of office. He thought, with the Chairman, that all committees should emanate from the council. He had no doubt that any suggestion of Mr. Mayall's would be considered by the council. He pronounced the subject one of the greatest importance. He had been engaged in comparing the working properties of different lenses whenever the weather permitted, and other gentlemen had been similarly occupied, and he was sure that he did not feel himself in a position to pronounce an opinion, and considered that it would be much more difficult for a committee to meet together and come to any definite conclusion. The only way that any satisfactory one could be arrived at, would be by a certain number of lenses being supplied to each gentleman of the committee to work with for a season, taking pictures with them under all circumstances, making careful notes of their performances, and giving their results in the form of a report to the Society, and then leave the members of the Society to form their own conclusions. He did not think that taking a lens, and looking at the image produced by it on the ground glass, and comparing it with another, would be a proper test, although one certainly might see if the *lines* were straight and the light good.

The CHAIRMAN stated that it would, perhaps, be satisfactory to Mr. Mayall to know that the council had that very evening been engaged in a discussion upon the precise subject; and the difficulty which struck the minds of them all was, that although you might get a very excellent lens from a maker, and which might prove very superior in character, yet that you could not be certain if you wanted another similar one that you could obtain it.

A member was about to second Mr. Mayall's motion.

Mr. LE NEVE FOSTER rose to order: the question was one of business of the Society, which could only be discussed by the council, or by members at a special general meeting convened for the purpose. The ordinary general meetings were for the purpose of reading papers. With all due deference, although he might be wrong, he suggested that Mr. Mayall should withdraw his motion, or, rather, that the Chairman should not accept it.

Mr. HARDWICH protested against the appointment of a committee to be worked in the way Mr. Mayall suggested. If the committee were appointed it ought to discuss the principles of manufacture of the lenses. When a member of the Society comes forward with a formula and offers it to the Society, then the Society is at liberty to communicate it to the members, and to state in the Journal what are its abilities *in their hands* to accomplish. If they found a defect in any particular kind of lens, they should state it with such recommendations for remedying it as might suggest themselves; but to say that they found one maker's lens better than another's would be decidedly invidious. How again do we know that any optician is able to produce them uniformly good? Would twenty lenses from the same maker be all equal in quality? Angry feelings would be generated in the Society, and thus more harm than good be produced.

Mr. MALONE agreed with much that Mr. Hardwich had said, yet, nevertheless, joined issue with him and the gentlemen on the other side upon the whole subject. For a long time he (Mr. Malone) had advocated the formation of this committee, and had been told by gentlemen who were interested in the management of the Society that they could not, as a body, give an opinion, or enter into an examination of questions of this kind, and yet, in the face of that assertion, at our last meeting a proposition was made in a very ambiguous manner for the formation of a committee for the investigation of collodion. He was not present, but it appeared to him, from the report, that the committee was together to have an opportunity of comparing a presupposed better collodion with others, the condition being that the makers of other kinds should communicate their method of manufacture.

The CHAIRMAN requested Mr. Malone to confine the discussion to the question of the appointment of a committee for the investigation of lenses, and expressed an opinion, that if the question were whether the power of appointment were vested in the Council or in the present meeting, that question could not be discussed without previous notice.

Mr. MALONE still thought that if the Society allow the formation of a committee for the examination of collodion, it should, upon the same principle, allow one with respect to lenses.

Mr. MAYALL would simplify the matter by withdrawing the motion, and make it a recommendation or suggestion to the Council. He cared not from whom the committee emanated, provided he got it; but it was advisable to be in order if they could.

The CHAIRMAN stated the council would not lose sight of it.

Mr. MAYALL said he would not lose sight of the subject, if the council did.

The CHAIRMAN then appealed to the meeting for opinions upon the interesting subject of lenses, and also, personally, to Mr. Voigtlander, but no discussion ensued, upon which

Mr. HARDWICH stated, that finding that a member of the Society, who had promised to read a paper at that meeting, was prevented by illness, he (Mr. H.) had hastily thrown together the following remarks upon some dry collodion experiments which he had made in conjunction with Major Russell. The observations were made

while working in the Laboratory of King's College, and other places, upon the question of the manipulation of dry and wet collodion.

The following is an abstract of Mr. Hardwich's paper:—

After stating that the absence of free iodine, and the presence of bromides in proper proportion, were not the only points of consideration with regard to collodion for dry plates, and comparing the qualities of those collodions made from pyroxyline, producing films of a contractile and horny character, or of a powdery nature, he gave the preference to the former for securing delicacy of half-tone, and to the latter for intensity of image; but, inasmuch as the great intensity is with dry collodion plates, apt to degenerate in practice into the formation of negatives: having too violent contrast between light and shade, and too little of the chief charm of first-rate photographs — middle tints — he considered it advisable, if possible, to employ for dry plates the former kind, although it might perhaps involve extra trouble and difficulty; the chief being, perhaps, liability to blistering during the developement, and another, the frequent stripping-off of portions of the film during the subsequent drying, especially when conducted by the aid of artificial heat.

He mentioned various experiments made by Major Russell, to whom he was indebted for some valuable hints connected with dry processes; amongst others, that of removing the whole of the free nitrate of silver by means of a weak solution of salt and water, afterwards washing the plates in pure water, and then, in order to attain sufficient density of image when developing, giving a final wash before drying the plates, previously to their exposure, with saturated solution of gallic acid. It being requisite, before application of the last solution, to make sure of the absence of free nitrate of silver that necessitates the employment of the salt and water.

He approved of the plans recently adopted of coating the glasses with a substratum of some other material previously to the application of the collodion, partly in order to attain more perfect adhesion of the film to the glass, and partly to gain more exalted sensitiveness. He considered that to Mr. Barnes photographers are really indebted for the suggestion of a film applied in the manner indicated, as can be readily shown by reference to the second edition of that gentleman's pamphlet on the preparation of dry collodion plates.

He then considered the various materials that might be employed for the preparation of the substratum, and desired if possible to avoid the use of gelatine or albumen, because if, as was very probable in preparing the plates, a portion of either of these substances became attached to the backs of the plates, and thus would not be subsequently covered by the collodion, it might, and probably would in time, tend to disorder the nitrate of silver sensitising bath.

He had tried therefore to substitute something upon which a solution of nitrate of silver would be inert, and had employed for this purpose, with some success, a solution of *caoutchouc in benzole*, in the proportion of two grains of the former to one ounce of the latter. This solution had the advantage of being readily applied to the glass without heat, the benzole evaporating in a few minutes of time, and the mode of application being precisely similar to that of collodion itself.

Plates so treated might be subsequently prepared by any of the methods for dry collodion.

By using his ordinary negative collodion he conceived that he had gained an advantage in the time of exposure being reduced nearly one-half.

Specimens were exhibited, showing great delicacy of half-tone. The author alluded to some disadvantages that were at present apparent, but which might probably be obviated; for instance, although more sensitive, he considered that the plates prepared thus, would scarcely keep quite so long without deterioration, and that Mr. Rosling, who had tried them for collodio-albumen plates by Taupenot's method, found that a peculiar rupture of the film when drying is apt to occur, the cracks appearing in circular lines.

Mr. MAYALL had seen the specimens, and was still of the opinion that he could produce a better picture with albumen alone, than with a mixture of albumen and collodion. Mr. Hardwich's spreading a thin coat of India rubber upon his glass, got rid of many imperfections in the glass, but he (Mr. M.) was afraid it would introduce many others. He preferred confining himself to as few surfaces as possible, and more particularly in dry processes; he believed also that upon that subject there ought to be a committee, as the wet process was becoming so valuable, and as the keeping qualities of a wet collodion plate could be suspended for three quarters of an hour, we had not the same difficulties now to contend with as formerly. It was the suggestion of Mr. Maxwell Lyte, of very small quantities of nitrate of magnesia in the bath. As Mr. Shadbolt was present, Mr. Mayall stated that he knew a gentleman in Perth who had been working the honey process with a success he (Mr. M.) had not seen equalled, and he thought he could bring that gentleman to the next meeting of the Society. Mr. Mayall would be happy to join any two or three others to compare the merits of albumen alone, or would undertake to teach any six gentlemen, and devote an hour a day to them, until they were perfect in the albumen process alone, in which case, by the end of this season, a series of notes could be made which would be very valuable. He had a horror of mixing things: two films he thought enough, but Mr. Hardwich now proposed a third. He (Mr. M.) could say very little upon the paper which had been read, for he thought the experiments were comparatively new and incomplete, but if Mr. Hardwich would supply him with some of the material he would endeavour to experiment upon it, and discuss it at the next meeting.

Mr. MALONE stated that he had Mr. Mayall's horror of mixtures, but inasmuch as albumen alone was not so sensitive as albumen on collodion, the mixture must be adopted. There is a peculiar crispness with albumen alone which is superior to the collodion with which no albumen is used, and the admirable result of albumen alone is retained in albumen upon collodion.

Mr. MAYALL forgot to add his belief that Mr. Malone, and all the operators upon albumen alone, lost sight of the great principle he had stated in a paper on the subject, that of exciting the albumen *with dry vapour of iodine*, by passing it over the iodine box for two minutes before it went into the silver bath, which made it quite as sensitive as collodio-albumen. He thought there was more to be done with gaseous iodide on a film of albumen and gaseous bromine than has hitherto been done. He believed that Mr. Malone himself, in the *Athenæum* some years since, suggested a small portion of bromine to increase the sensitiveness of albumen.

Mr. MALONE was much obliged to Mr. Mayall, but still thought the combination of collodion and albumen preferable. Mr. Hardwich (having made public his mode of operation) would excuse him for asking whether, when making pyroxyline, upon failure in producing the desired result he might take the specific gravity of the acid as sufficient; in fact he thought Mr. Hardwich had modified his opinion upon that, and had found that owing to the difficulties of manipulation, science was of no avail, and that one must go by the rule of thumb, and add water before the desired result could be obtained; and he would also ask whether the kind of cotton employed matters, and if so, what kind of cotton should be used with that formula?

Mr. HARDWICH stated he thought that the specific gravity of the acid was not of itself sufficient, but it was the only guide he could give, and that would sometimes deceive, because the acid might occasionally contain sulphate of potash, or another substance which would throw out all their calculations. Make your mixture from the specific gravity, and if you find it is too weak then increase it. With regard to the best kind of cotton, he was not quite certain; he had twenty different kinds from all parts of the world, but in the meantime he used the best he could get, combed free from the dust or straw, or whatever it might be. He must say, if one failed the first time try again.

Mr. SEBASTIAN DAVIS prepared some plates during the last twelve months, went into the country and exposed them. As far as the dry process went he could not alter them, except as to time of exposure, and he found that to bring out the details of shadow and the foliage properly he wanted from ten to twelve minutes.

Mr. F. G. ELLIOTT, some time ago, having worked with the dry process had used common cake india rubber dissolved in coal tar naphtha as a substratum, and it kept the film from moving, but it afterwards cracked in all directions.

It being late the meeting then adjourned.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

AT the ordinary monthly meeting of the above Association, held at Myddelton Hall, on Wednesday, the 30th ultimo, Mr. JOHN BARNETT in the chair, the minutes of the previous meeting having been read and confirmed, the following new rules were proposed and adopted:—

"That at the ordinary meeting in February the officers for the ensuing year be nominated, any member being at liberty to propose names."

"That the payment of five guineas in one sum constitute a life-member."

The proposed alteration in Rule 4—"That the word 'Vice-president' be expunged, and the words 'Two Vice-presidents' be

substituted"—was, after a lengthened discussion, negatived by a majority of two.

The following report was then read by the Secretary, and agreed to:—

SECOND ANNUAL REPORT.

The Committee has great pleasure in laying before the members the second annual report, and congratulates them on the increasing prosperity of the Association.

The following papers have been read at the ordinary monthly meetings:—

By Mr. J. DUTTON ......" *On some Experiments connected with the Waxed-Paper Process.*"
„ Mr. J. A. JUDGE ...." *On the Wet Collodion Process.*"
„ Rev. J. WINTER......" *Observations on the Calotype Process.*"
„ Mr. G. SHADBOLT ..." *On Focussing the Camera.*"
„ Mr. T. A. BARBER..." *On the Causes of Failure in the Oxymel Process.*"
„ Dr. RYLEY ...." *On the Modification of the Collodio-Albumen Process.*"
„ Mr. MCCRAW........." *On an Iron-Printing Process.*"
„ Dr. HILL NORRIS ..." *On the Dry Processes.*"
„ Mr. M. HANNAFORD.." *On a New Iron-Printing Process.*"
„ Mr. M. S. LEGG......" *On the Delineation of Microscopic Objects.*"
„ Mr. M. HANNAFORD.." *On some further Experiments in the Iron-Printing Process.*"
„ Mr. M. HANNAFORD.. *Ditto* *Ditto.*

A number of subjects of interest and importance have been brought forward for discussion, and many novelties and improvements in apparatus, &c., have been exhibited at each meeting; and the Committee takes this opportunity of again thanking its friends for their kind assistance in promoting the welfare of the Association.

The Committee feels gratified that the substitution of *The Photographic Journal* for the *Journal of the Photographic Society* has given general satisfaction to the members, and desires to express its high appreciation of the services rendered to the Association, and the art of photography generally, by Mr. Shadbolt, the esteemed Vice-president.

Although the expenses during the past year have been considerably augmented, in consequence of the increased outlay caused by the distribution of the Journal fortnightly, instead of monthly, the presentation of the photograph of Rochester Bridge to each member, and from other causes, the Committee has great pleasure in stating, there is still a balance in hand; and trusts to be in a position, not only to continue all the advantages hitherto enjoyed by the members, but to embrace any opportunity that may offer of increasing them.

The assistance and co-operation of the members are invited in procuring a negative, from which to print a presentation photograph for the ensuing year.

In conclusion, your Committee cannot forbear congratulating the members generally upon the good feeling evinced at all the discussions that have taken place, and the universal readiness to communicate information for mutual benefit, which has formed so marked a feature at all the meetings.

(Signed) J. BARNETT, *Hon. Secretary.*

It was moved by Mr. BARBER, seconded by Mr. HILL, and carried unanimously:—

"That the members view with regret the resignation of Mr. J. S. Moon, through ill-health, from the office of Hon. Secretary, and that the best thanks of the Association be given to him for the very efficient and kind manner in which he has discharged his duties since the formation of the Society; and that this expression of their regard for him be added to and printed with the report."

The CHAIRMAN having announced that as this was the anniversary meeting, it would be necessary to choose officers for the ensuing year; and, there being no opposition to their nomination, the following gentlemen were elected:—

CHARLES WOODWARD, Esq., F.R.S., J.P., &c., *President.*
GEORGE SHADBOLT, Esq., *Vice-President.*
D. W. HILL, Esq., *Treasurer.*
JOHN BARNETT, Esq., *Hon. Secretary.*

The Committee were then ballotted for, and from the eight nominations the six undermentioned gentlemen were elected:—Messrs. Barber, Hannaford, Hislop, Moens, Moon, and Shave.

The following gentlemen were duly elected members of the Association:—Messrs. F. Eck, H. Evans, J. Gowan, E. Heseltine, G. Peevor, G. W. Simpson, Davis Sims, and J. Whitehead.

Mr. DAWSON exhibited some very beautiful photographs by Wilson, of Aberdeen.

Mr. W. HISLOP, F.R.A.S., described and exhibited his lantern for illustrating lectures, &c., by means of photographic transparent positives on glass, for the enlargement of microscopic objects, and for other purposes (see page 92).

A vote of thanks was passed to Mr. Hislop for his description, and the pleasing exhibition which accompanied it.

It was moved by Mr. MORLEY, seconded by Mr. BINGHAM, and carried *nem. con.*:—

"That the thanks of the Association be given to all the officers for the past year, for their good management and successful efforts in bringing the Association to its present state of prosperity."

After the usual compliment to the Chairman, the meeting separated until Wednesday, the 27th instant.

LIVERPOOL PHOTOGRAPHIC CLUB.

ON Tuesday evening last, the fifth meeting of the above Club was held at Mr. Keith's Rooms, Lord Street.

After the reading of the minutes, Mr. FORREST addressed a rather numerous meeting, by saying, that he was much indebted to friends, who had suggested the use of mercury, as increasing the intensity of the photograph. He had found, as it was foretold, that the mercury had induced a ready deposit of the copper from the battery; but he had yet to complain of a difficulty in more strongly marking its half-tones, and the imperfect delineations of more delicate photographs. To obviate this and further the additional deposit of the copper, he had surrounded the picture on every side with copper wire; and was disposed to think that the covering of copper gauze wire would farther facilitate the deposition.

Mr. LEITHEAD advised tinfoil as being a more ready conductor of the necessary weak galvanic current.

Mr. COREY conceived that a more subtle means of inducing a current was not the object in view; but the greater susceptibility of the surface to receive the effects of that current was the requisite sought for. That, as it had been admitted, the application of mercury, whilst it intensified the image, also facilitated the formation of the film of copper, the object must be to increase that susceptibility. Now, all electrotypists were aware that, when articles were to be coated with metal, certain portions obstinately repelled the influence of the battery, and a deposit could only be accomplished by washing with a solution of protonithate of mercury. Why not, then, increase the portion of mercury already united with the silver, by washing with this solution?

Mr. DUTTON (a visitor) remarked that the great reducing qualities of grape sugar, and of the essential oils, might be rendered available, inasmuch as they reduced silver in its metallic form, so also copper might be thrown down in graduated proportion upon the surface of the glass by their use.

Mr. R. COOK advocated the application of phosphorus, dissolved in bisulphuret of carbon, to facilitate the farther deposit of silver.

Mr. KEITH could not see the feasibility of this mode, as an even film would be left over the entire surface of the plate, obscuring lights and shadows alike.

Mr. COREY could see a fresh field opened out by Mr. Cook's idea, which would, he hoped, do away with the cumbrous action of the battery altogether. He remembered the very earliest efforts of Mr. Berry and himself, and now possessed a negative taken five years ago. Finding that the negative was too weak, Mr. Berry, after the photograph was varnished, had washed it with an alcoholic solution of chloride of gold, and then blackened with sulphide of ammonium. This process was frequently brought before the notice of members. Now, he was firmly of opinion that this would give the adequate intensity Mr. Forrest required, and would place this negative at his disposal.

Mr. FORREST accepted the offer, and would report its effect at the next meeting.

Mr. DOYLE (a visitor) introduced a few specimens of what he proposed to call Chromatypic Printing. True, it was based upon Mr. Hunt's process, but he had differed in certain particulars. He would feel at liberty so far to announce, that it was by the use of bichromate of potass, and metallic precipitates, resulting from various re-agents, forming pigments, exhibiting a diversity of tone, and variety of hue, entirely different from silver.

These specimens were remarkable for a very clear and sharp definition, but were wanting in force.

Rev. T. BANNER exhibited a very compact little contrivance for sensitising and developing stereoscopic plates in the open air.

Half-way down the three legs of an ordinary camera stand a shelf was supported; a covering of velvet, impervious to light, was stretched from this, and over the top. Having small sleeves fitted by elastic bands to the wrists, with a coloured glass eyepiece, and a small window of the same, an expert operator, with the focussing cloth thrown over his head, was enabled to see all the needful operations of his own handiwork, as distinctly as if unfettered in a room. Its portability and simplicity were much commended.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the evening of the 6th instant, at the Rooms of the Literary and Philosophical Society, Mr. SIDEBOTHAM, V. P., presiding.

A new member was elected, and Mr. Hardwich was elected an honorary member of the Society.

The CHAIRMAN then made some lengthened remarks on micro-photography, &c. [See page 91].

After the remarks made by Mr. Sidebotham, a number of specimens taken by Mr. Dancer were then exhibited to the members by the aid of a microscope. Amongst them were the following, prepared specially for the occasion:—A page of printing, from Quekett's "Treatise on the Microscope," reduced to such size that the whole to the volume of 560 pages could be contained in a space one inch long and half-an-inch broad,—(*fig.* 1)—the page contained 2118 letters. Two pages of Quekett's "Treatise on the Microscope," reduced to one-sixteen hundredth part of a superficial inch; they included 3631 letters, and at the same rate the whole volume could be contained in a space of three-eighths of an inch square—(*fig.* 2). This specimen excited considerable attention, being so exceedingly minute, notwithstanding which every letter was perfectly sharp and legible as the original printing, under a high magnifying power. Another specimen contained the written name and address of the Chairman, along with the date, in a small space the size of a hole punctured by a fine needle.

Fig. 1.

Fig. 2.

At the conclusion of the Chairman's remarks,

Mr. DORRINGTON read a paper to the Society, *On Printing Glass Transparencies.* [See page 91.]

Mr. SIDEBOTHAM said he thought Messrs. Dorrington and Nevill's process a very good one, having tried and found the plates more sensitive than collodio-albumen.

A great number of stereoscopic transparencies were handed round, and were considered exceedingly beautiful, being very brilliant and good in half-tone.

Mr. PATTISON also showed some specimens taken by him—taken with dry collodion on the gelatine, which were much admired.

Mr. PARRY called the attention of the meeting to the circumstance of his having written on the collodio-albumen plate with a black lead pencil, and on developing the plate he found the traces of the pencil, though faint, developed very black and sharp.

Mr. MABLEY explained a curious circumstance which he had met with: having coated a prepared collodio-albumen plate with collodion, for the purpose of taking a picture by the wet process, he found, after exposure and developing, that the picture developed very intense, and having afterwards rubbed the collodion off the surface of the albumen, and again coating it, and exposing, and developing, and afterwards rubbing it off again, he found no traces of the picture in the collodio-albumen film.

A vote of thanks was passed to the Chairman and the proceedings closed.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE Monthly Meeting of this Society was held at the Odd Fellows' Hall, on Tuesday Evening, the 29th ult. WILLIAM HOWELL, Esq., one of the Vice-Presidents, occupied the Chair.

The lecturer for the evening was Mr. JOHN JOHNSTONE, of New Street, Birmingham, one of the most scientific photographers in the Midland district.

He commenced by saying that it had been his intention to have devoted the evenings of the previous week to writing out what he intended to bring before them that evening, but as an unforseen occurrence, of rather a disagreeable nature, had absorbed the whole of his time, he had not even had time to turn the matters over in his mind.

He believed the subject announced was, "*On some of the Essential Requisites in the Production of a Good Photographic Picture.*"

One of the first essentials was a good camera-box and lenses. The interior of this box should have two or three diaphragms covered with black velvet, so placed as to prevent any reflection falling on the area of the picture. In his (Mr. Johnstone's), early experiments on lens making, he always found for a single lens that the old original curves of Dollond, for telescopes, was really a better construction than the modern make. In all the older makes, the concavity of the outer flint surface is much greater than the modern form, and hence arose a flatter field. It would be impossible to use a large opening with a single lens, to get a perfect image, and consequently, in taking portraiture, where the large opening is essential for the sake of diminution of time, there the second lens is brought into play, to counteract the aberration of the oblique rays. In Voigtlander's lenses there was always noticeable a peculiar brilliancy of definition in the centre of the image on dead glass, and he (Mr. Johnstone) never met with a French lens which had this peculiarity in such a high degree. He believed this was to be attributed to some extent to the kind of glass Voigtlander uses. For many years all his flint was made at the glass house in Blackfriars, where Dollond's glass was originally made. It was considered a light flint, the specific gravity being about 3·2-10ths, while the specific gravity of some of the French lenses was as much as 3·6-10ths, and consequently a much denser and more refractive glass. But though there was an advantage arising one way from the use of heavy flint, there was a disadvantage arising in another. If they took two prisms, one of crown and one of flint glass, and allowed a beam of sunlight to fall upon them, so that the two spectra should be exactly of the same length, it would be found that though the extremes of the violet and the red fit exactly, the central part of the spectra do not. Consequently, no lens formed with two pieces of glass can ever be brought to be perfectly achromatic as to colour. There was always a little outstanding colour that never could be overcome; and in proportion to the density of the flint, the greater the disparity of the spectrum. Dr. Blair overcame the difficulty many years ago by a fluid lens, and Mr. Archer, of London, was said to have made one on the same principle.

After pointing out the necessity of having the edges of the lens a dead black, and of placing two or three diaphragms in the tube, to prevent reflection from oblique rays, Mr. Johnstone went on to speak of the defects found in photographic paper, which is not now so good as some made by Turner, eighteen or twenty years ago. On visiting Turner's mill eight or nine years back, he found a salt in use, named anti-chloride, which, on testing, he found to be a sulphate of soda, and which no doubt materially affected the quality of the paper chemically. French paper is superior to ours in texture, but that is the only good quality it has. Owing to the size being of a resinous soapy nature, it is often alkaline, and is frequently deposited on the surface in little clots, which become detached in the fixing, completely spoiling pictures; and the artificial ultra marine, used in colouring French papers, having sulphur in its composition, probably accounts for the rapid decomposition of the sensitive surface. By immersing French paper in a solution of chlorine, and using a little warm water, both the blue and the insoluble size might be removed, and when dried and re-sized with gelatine, coagulated with alcohol, it might be iodised or sensitised in the Talbot manner, and would be found to work perfectly.

As to manipulation, he believed the single and double washings were alike good; but there was one advantage in the single washing, when they had the silver and the iodide combined: they had a large excess of iodide of potassium, which dissolved the metallic particles in the paper, and freed it from black specks. Remarking as to the waxed-paper process—he hoped ere long to bring before the public a theory of photographic action that would explain how it is that a sheet having its fibres filled up with bees' wax, bears keeping in a sensitised condition, stands developing so much longer, and produces a clearer negative than a plain sheet of paper; and likewise to explain the reason of every change produced through the whole range of photographic action.

Mr. Johnstone referred to collodion and the process of manufacture, remarking that probably the time would never come when they would get a collodion perfect in all things. With new collodion you get a a full developement, but it is feebler than if it had been older; keep the collodion for a few days, and vigorous pictures are obtained; a few days more, and lights are high, shadows intense, and a longer time in the camera is required to bring out the half tones. In the developing solution, a certain amount of acid was required, and in the bath acid was also desirable with some collodions. The bath and the collodion should always be accurately adapted to each other. With new collodion, and a neutral bath, the image starts out rapidly all over when developed, but with old collodion, using the same bath, it does not so act. The high lights begin to exhibit themselves first, and it gradually goes on until checked at the proper time, and when fixed there is a well balanced picture, lights intense, and the blacks clear. The same bath is not adapted for

a new that is so for an old collodion. A neutral bath would work safely with an old collodion, and not with a new one; for this reason, that with a neutral bath, and with a new collodion, the affinities of the different materials are so nearly balanced, that if you happen to develope slightly beyond the proper time, you get a foggy result.

But with the same bath and old collodion, you have got a little free iodine in the film. Of course the decomposition takes place in the nitrate of silver bath, and the iodide of potassium in the film, but the free iodine takes up a portion of silver from the bath, and leaves a little nitric acid free. This being of necessity in the film in the first place, the consequence is that when you come to develope, after a slightly longer exposure, a much clearer picture is the result, as the free nitric acid in the film prevents all tendency to fogging. The acid developer will not fully make up for this quality which the old collodion possesses. When you put your coated plate into the bath for a given time, the whole of the iodide salt with free iodine in the film is changed into the silver salt, leaving a little free acid. A bath being neutral, it will have a tendency to take up a portion of nitric acid from the film, so that if you leave a plate in double the time of the former plate, you cannot expect the same results, as you have an alteration of the condition existing before. Another point connected with collodion was the cause of the change which takes place in the collodion solution after being iodized. They knew, from experience, that iodide of potassium, when used alone, changes in a few days—that iodide of ammonium changes more rapidly still—and that iodide of cadmium does not visibly change. The cause of the change had been attributed to the ether becoming acid, from age or other causes; but he conceived that it rather arises from the decomposition of the gun-cotton, which is a very changeable substance. After referring to the improvement which had been the result of the introduction of gold, and mentioning that he used common salt in his toning bath, six or seven years back, Mr. Johnstone referred to the carbon printing process, and the ink process introduced by M. Sella. In the latter, bichromate of potash and sulphate of iron were used, the paper being exposed to the light under a negative, the parts where the light has not acted being afterwards washed out, and the sheet subsequently washed with a solution of gallic acid. The result was a kind of ink, but he thought it very clear that the originators of the process knew but little of the principles of dying or calico printing. It is well known amongst dyers, that in using a peroxide of iron to produce a black with any material whatever, it will not be a lasting black, but when exposed to the atmosphere, will become of a rusty brown. In producing a good lasting black, it is necessary that the iron should be in a state of protoxide, and that the vegetable matter combining with it to form a black, should, previous to combination, be soluble. Gallic acid is not a good material for obtaining a black; tannic acid being preferable. He then recommended the members curious in experimenting, to take chromate of potash, with sulphate of iron to prepare the paper, expose it, wash out all that is soluble, put the print into a flat vessel, with a strong decoction of tannic acid upon it, and when boiled for a time, you get a sheet of solid black. Wash it well, put it into a solution of chloride of lime, and eventually the parts where there is no mordant will all bleach white; but where the mordant has become fixed in the paper, that will resist the chloride for a sufficient amount of time to allow other parts of the sheet to become clear. He thought, that in this way, a more permanent black dyed sheet may be produced than by any other plan which has been suggested.

Mr. Osborn in moving a vote of thanks to Mr. Johnstone alluded to the benefit the society had already received, in having amongst them a man of Mr. Johnstone's high attainments. With regard to carbon printing, the process mentioned by Mr. Johnstone, as suggested some time since, had been re-discovered by a Mr. Mabson, but this matter had been put right in the Journals. He hoped that they would have to listen often to Mr. Johnstone's floating ideas.

The resolution was passed unanimously.

Letters to a Young Photographer.

No. VIII.

My Dear Eusebius,

There is one little operation yet to be performed before you can take a picture, which, although not before alluded to, has not been lost sight of. But I have kept it in the background, lest the contemplation of so many items of preparation should discourage you. Collodion pictures, I need not remind you, are taken on glass plates. And it is very important that the plates should be scrupulously clean. Now it might, at first sight, appear that any fool could clean a bit of glass; but give one to Betty, or to Buttons, and see how they will polish it off! You might be able to see your face in it, it is true; but your picture would develope up some inexplicable signs and wonders, which, in your simplicity, you will attribute to that —— collodion, or to that *cussed* developer, or to some other than the right thing. If you set your mind upon obtaining a good picture, you must clean your plates yourself. I always do mine, and I set about it in this fashion:—

If the glass is new from the glass-cutters, I apprehend there is nothing to clean off but greasy finger-marks, dust, &c. Now, strong alkali suffices to attack grease, and you may use *liquor ammonia*, if you stop your nose, or American potash, one or two ounces to the pint of water. Dip or soak the plates in this solution, and rub the glass all over with a soft nail-brush; this will effectually remove dirt and grease, and a good rinsing in plenty of clean water completes the operation. Set them up on one corner to drain, and before they are dry rub them over with a linen bag containing whiting. This white coating, when dry, preserves the plates from becoming again dirty, and in this state they may be kept any length of time; all that is required, when they are wanted for immediate use, will be to rub off the whiting with a clean linen cloth, and polish with a chamois leather — the plate resting on some folds of thick blotting-paper. You can easily recognise when the surface of the plate is perfectly clean, by breathing upon it. If it leaves a uniform veil, free from streaks or other defects, you may consider your plate fit for use. If the veil does not appear perfectly uniform, the polishing must be renewed, and always performed immediately before the plate is covered with collodion, as the particles of dust ever present in the atmosphere will settle upon it, and cause defects in the picture. It is well to keep a large soft brush for the express purpose of removing the dust from the glass plate before use.

Plates upon which pictures have been taken, sometimes require more active treatment, so as to remove matters that might disturb the integrity of the preparations employed in taking pictures. To make sure, I keep ready a quantity of diluted nitric acid, into which I put the plates, after they have been washed free from the collodion, &c., and treated with the potash; and I leave them in the acid for several hours. Upon removing them, they are to be washed in plenty of clean water, drained, and then coated with whiting, as before directed. In handling the plates, you will take care to avoid putting your fingers on the surface; but hold them by the edges, and finish the cleaning by wiping the edges also, to remove the dust that accumulates there.

The sharp edges of new glass plates will require to be taken off, else they will be apt to cut your fingers. For this purpose a piece of grit-stone answers very well. By a little dexterity you can work a groove in one side, into which the edge of the glass will slip, and you can make rough the two edges at once. I prefer the kind of glass known as "patent plate;" but your choice will, probably, be governed by the nature of your operations.

I am aware that some operators think it necessary to proceed in a much more complicated fashion when they clean a glass plate; but I think, in so doing, they misconceive the nature of the substance upon which they exercise their ingenuity. Generally speaking, the agents employed in photography exercise no chemical action upon the glass plates; but I have found a very adherent metallic deposit sometimes, which, however, nitric acid is effectual in removing. Those operators who recommend alcohol, tripoli, rottenstone, &c., appear to consider that the glass plate requires the same treatment as the silvered plates used in daguerreotype, forgetting that in these latter a chemical action has taken place in the substance of the plate, the mechanical results of which require to be removed by abrasion of the surface before the plate is fit to receive another picture. Nothing of the kind takes place upon the glass plate; and it is only when solutions and liquids of a certain kind are allowed to dry upon glass, that deposits, producing stains, difficult of removal, are formed.

If your head is cool, and your nerves are strong, you may now proceed to coat a glass plate with collodion. I have seen many a brave man undertake this operation, but not one that failed to tremble at the first attempt. So having screwed your courage to the sticking place, take the glass plate in your left hand, by the lower left-hand corner, resting it upon the lower portion of the second finger, the thumb over it; let the fore-finger run up the edge of the glass, towards the upper left-hand corner, to steady and control it in the various movements required. Holding the plate breast high, take the collodion-bottle in the right hand, and inclining the plate slightly towards the right, pour upon the centre a

steady stream of collodion, until there is sufficient to cover the entire plate. By a slight but dexterous inclination of the plate, the whole surface is quickly covered with the collodion—first to the upper right, next to the upper left, then the lower left, and lastly, to the lower right-hand corner, from which the excess of collodion is drained into the bottle. This operation is performed much more quickly than described; the chief care to be taken is to avoid the collodion "doubling"—that is, a fluid portion running over another portion that is becoming set, which, if it occurs, will destroy the homogeneity of the film, and, consequently, the picture taken upon it. The *modus operandi* of coating a plate uniformly with collodion is a *flooding*. I know of no better term to express it. If you do not soon succeed to your satisfaction, you had best get some one to show you how it is done; but I think a philosopher of your intelligence cannot be discomfited with one or two failures; and if you succeed unaided, your triumph will be the more satisfactory to your pride and perseverance.

In a few seconds (the number of which depends upon the composition of the collodion and the temperature of the operating-room), the collodion on the plate will become set; it is then ready to be immersed in the nitrate of silver bath, which you will prepare by dissolving one-and-a-half ounces of crystallized nitrate of silver in a pint of distilled water, and afterwards adding an ounce or two of old iodized collodion; these ingredients should be mixed in a large bottle, and well shaken; after a few hours repose, filter through bibulous paper.

Photographic Glossary.

Hydracids, or Hydrogen Acids—These acids are formed of one equivalent of hydrogen, united to one equivalent either of chlorine, bromine, iodine, fluorine, sulphur, selenium and tellurium. As hydrogen forms only a single acid with each of these elements, the formulæ of the hydracids are indentical. The hydrogen acids combine with bases to form salts.

Hydrogen—A gaseous substance, the lightest of all bodies, being fourteen-and-a-half times lighter than air. It is adopted as the unit of the scale of chemical equivalents. Mixed with oxygen, it detonates with great violence, and the product of the combination is water. It is a very powerful reducing agent, but has not yet been employed for that purpose in photography.

Hydrosulphate of Ammonia—A compound of hydrosulphuric acid and ammonia, sometimes termed sulphide of ammonium. It is a gas possessing a very fœtid odour, and is always employed in an aqueous solution, which, when pure, is colourless, but becomes yellow by contact of air. It is used to precipitate metals from solutions in the state of sulphides, and is employed in photography in the treatment of residues.

Hydrosulphuric Acid—A colourless gas of a very offensive odour. Water takes up about three times its volume of this gas, and acquires its properties. By exposure to the atmosphere, the solution becomes milky and deposits sulphur. This acid is employed in photography, to extract silver from solutions containing it, by forming an insoluble sulphide of silver.

Hypochlorite of Lime—Commonly called chloride of lime, which is an intimate mixture of chloride of calcium and hypochlorite of lime; it destroys the colour of most substances, and is employed for bleaching tissues and paper, and also as a disinfectant.

Hyposulphites—Compounds of hyposulphurous acid with bases. Hyposulphurous acid exists only theoretically, as it cannot be isolated. A very remarkable property of the hyposulphites is, that of dissolving certain insoluble salts of silver, as the chloride, &c.

Hyposulphite of Soda—A salt composed of soda and of hyposulphurous acid. It is obtained in large colourless transparent crystals. It dissolves the salts of silver, which are insoluble in water, such as the iodide, bromide, and chloride, while it attacks, only very slowly, the blackened salts of silver or metallic silver, thus forming a most useful fixing agent.

Image—When a lens is presented to a given object, the rays proceeding from the latter in passing through the lens are refracted, and unite, at a certain distance from the lens, its focus, and form there an *image* of the object. The relative sizes of the object and the image are determined by the distance of the object from the lens, and by the length of focus of the lens. Rules and tables, showing the size of object and image, focus of lens, and distance of object, may be found in Lay's Photographic Almanack.

Ink-Printing Process—A method of obtaining positive pictures on paper, by the employment of the components of common writing ink, viz., tannic acid and iron.

Insolation—A French term, signifying exposure to the sun's rays.

Instantaneous Pictures—By the employment of very sensitive chemical materials, under favourable conditions, negative pictures can be obtained by an instant's exposure of the prepared material in the camera. Pictures so obtained are termed instantaneous pictures.

Invisible Rays—Recent researches have shown that there are chemical and calorific rays in the spectrum, which extend beyond the extreme visible violet and red rays, some of which are made evident by being arrested by a solution of disulphate of quinine, or decoction of œsculine, or seeds of the datura stramonium. Glass, coloured with oxide of bismuth, has also a similar property to that of the solutions named.

Foreign Correspondence.

Paris, April 7, 1859.

PHOTOGRAPHY, after enjoying its period of hybernation, is waking up under the influence of sunshine and precocious summer heat, and the photographic world resembles a hive of swarming bees. The results of last year's excursions are coming out, and when our Exhibition opens we may expect a treat, the like of which has never before been vouchsafed to us. The great rage with the public is for stereographic pictures, and artists have not been slow to minister to the prevailing taste. Many of the series of views display a vast amount of energy and enterprise, even as commercial speculations. There is no corner of the globe so distant, provided it be picturesque, that will not repay the expenses of a voyage thither, and yield a good surplus besides. The World in the stereoscope! Here is work enough cut out for a generation of photographers, work they never so nimbly. And it is not merely the *univers pittoresque* that the photographer brings home with him, but the *monde scientifique* also. In M. Smythe's *Teneriffe*, England has sent us but one scientific stereoscopic contribution; but for that one we can send you twenty in return. There is the mountain chain of Mont Rosa and the panorama of Mont Blanc, the first photographed by M. Bisson, sometimes at an elevation of upwards of three thousand feet above the level of the plains; the second photographed by M. Martens, the scientific value of which has been recognised by the *Académie des Sciences*. M. Ferrier has overrun the Alps, like a true mountaineer, from the Wetterhorn to the Appenines, and his views are the perfection and wonder of the picturesque. But I will now confine myself to describing the series by M. Bisson, taken during his ascent of Mont Blanc, which are not stereoscopic, but are in two series, one very large, the other smaller, suitable for the tourist's album or the artist's portfolio.

The series commences with the starting point, the Priory of Chamounix; and the views from this charming valley, surrounded as it is by the most celebrated mountains of Europe, show us the general physiognomy of these giants of the Alps. A most splendid panorama presents itself to our view: there is the Forest of Montanvers, with its sombre foliage contrasted against the white glaciers; beyond rises a series of gigantic mountains, from the Bochard to the *Col de Baume*, whose snowy crest cuts the distant horizon. To the left the wooded heights of *La Flegère* close the vast circle, in the foreground of which the pretty villas of Chamouny rise as out of a luxurious carpet of green verdure, through which the stream of the Arve flows, like a ribbon of silver over a mantle of dark velvet.

From this point the photographer commences his laborious ascent, and from every suitable point of view the eye is gratified and astonished with new wonders. There is the *Glacier des bois*, rising abruptly between the *Aiguille du Bochard* and *Montanvers*. The eye measures with terror the height of this colossal peak, yet it is but a step of the ladder whose summit is in the clouds. Still ascending we soon reach a little wooden chalet surrounded with a flower-garden—the *Auberge de Chapeau;* here another magnificent spectacle presents itself—glaciers, icy peaks, bottomless chasms, exhibit a varied grandeur and majesty—contrasts tha awaken ideas of the Infinite. Another stage higher and we reach

Le Courtil, an oasis in a desert of ice, a meadow enamelled with flowers amid a perpetual winter: here every emotion merges into that of solemn awe inspired by the scene. The summit of Mont Blanc appears nigh, rising a snow-crowned monarch, King of the Alps, which bow their heads around him. Here the artist pauses in his perilous ascent: it was scarcely possible to ascend higher with a photographer's baggage; but with a supply of dry collodion plates the attempt may be renewed, and a new store of wonders opened to us.

The peculiar excellencies of these productions can only be fully appreciated by one familiar with photographic perils and difficulties, and perhaps none greater are ever encountered than attended the production of these views. You will doubtless soon have an opportunity of admiring them yourself, for they will be put into circulation immediately the Exhibition is opened.

The other M. Bisson (you know it is always Bisson *frères)*, while his brother was engaged in Switzerland, occupied himself in photographing the architectural riches of the south of France. Although this section of the country had been previously visited by three skilful artist photographers, yet M. Bisson, by selecting new points of view, has contrived to give an air of novelty to things familiar. The cities of Arles and of Nismes, especially, have furnished him with some of the choicest productions of photographic art. The interior of a Cloister has all the magical chiaroscuro effects of a dioramic picture. From the Museum of Aix, M. Bisson has brought copies of the paintings attributed to the hand of the good *Roi René*.

I must not omit to add that in stereoscopic pictures a new class of subjects is obtaining great popularity: these are animated groups, illustrative of the songs of Beranger; the principal scenes in the comedies of Molière; with romances illustrated in series of twenty subjects; scenes from the *Bal d' Opera;* national dances, *cum multis aliis*.

From this you will gather that the horizon of photography is not diminishing, but rather widening every year. The public accepts these new offerings with great avidity; and very many among the productions of this branch of photography are subservient to the purposes of education. J. P.

New York, March 16, 1859.

THE item of most interest to photographers here at present, is the result of the suit of *Cutting* against a practitioner of the art for an infringement of his patent, dated July 11th, 1854, for the use of *bromide of potassium* in combination with collodion, according to the following extract from his specification. After describing the preparation of the collodion, he says: "In order to excite this collodion, take a deep one-ounce vial — introduce two-and-a-half grains of bromide of potassium, and add water, drop by drop, to make a saturated solution. In this solution, dissolve two-and-a-half grains of iodide of potassium; then add one ounce of collodion, and shake well. Let it settle clear, and decant for use. The solution must be decanted every day. In order to make the most sensitive collodion, I dissolve the bromide and iodide of potassium and the collodion *in a saturated solution of carbonate of ammonia in water*." This he calls the "Mezzographic Process." The italics are mine. The *collodion* must be dissolved in a saturated solution of carbonate of ammonia in water! His claim is, "The employment of bromide of potassium in combination with collodion," and under this he threatens every one with an injunction to restrain from the use of *any* bromide, whether in collodion, "dissolved in carbonate of ammonia," or otherwise, unless they purchase a license.

However, all is not yet lost — for, although the courts have decided that his patent is valid (judgment went by default), a certain editor has declared to the photographic world, in a circular which I send you herewith, as a specimen of his wondrous powers of *blarney*, that he desires "to be the means of contributing at least *five hundred dollars* (!) to a common fund for protection." This circular is the only notice the practitioners have received of the terrific onslaught to be made on them.

The process is said to be also patented in England, when, if so, those who dissolve their salts of potassium and collodion "in a saturated solution of carbonate of ammonia in water," may also expect an injunction — unless they shelter themselves under the wing so maternally raised to accommodate all who need its defence.

At length a photographic society has been formed in New York —at least, so it was stated in one of our newspapers a few days ago in a paragraph of three lines, alluding to it as *un fait accompli*, while the last of the lines read, "no name of any prominence appears in the proceedings." This remark does at first sight appear rather disparaging; but on criticising it, especially after obtaining an insight into the whole subject, it will be found to be as superlative a degree of praise as could, under the circumstances, be expected, since *all* our *more* prominent men were there. Our *inventor-general* issued the invitations, led off, continued and concluded the proceedings, all of which will, no doubt, appear in his journal, which is so extensively advertised as being "emphatically the organ of the art in America," notwithstanding which the practitioners so emphatically ignore its existence, that when its proprietors have a resuscitated process, or an antiquated form of apparatus to re-invent, they must have recourse to a flood of post-paid circulars to make it known to those who would use such things — an advertisement in *their own organ* being utterly unavailing for the purpose of reaching them.

To return to the society. The meeting was called by private invitations, of which it is said about forty were issued. Of those invited, very few were present — some sent excuses, whilst the greater number paid no attention whatever. But those present declared the society organized, and elected themselves its officers, besides doing every thing else requisite for the occasion, except designating "an organ." This ceremony was omitted, because the editor of the monthly advertiser was there also, and was very desirous of "having a finger in the pie," as well as our most *prominent savant* himself. With these luminaries of the art (each a host in himself) present, it is clear the newspaper reporter must have been incompetent to distinguish wherein *prominence* consisted.

By the way, European inventors must look to their laurels, or we shall henceforth show *our priority* in every useful invention, and each successful process that can possibly be thought of. This we shall accomplish in a very peculiar manner — a genuine invention of our own, with which *you* have nothing to compare.

The monthly advertiser, under its grandiloquent name of *The Photographic and Fine Art Journal*, for December, 1858, was only issued about the 1st March, 1859; while the number for January 1st is not yet out, nor is it probable it will be out for some time to come. Now it is very possible, that the number for January 1st will contain a notice of the formation of the new society, which event did not take place till March, or more than two months after it purports to have been published — thus beating the electric telegraph all to pieces in announcing new inventions, &c. Will not this become a power incapable of being withstood in our race for priority? As an example: Some one invents a new lens in Vienna, or elsewhere, and it gets described in *The Photographic Journal*, say for the 1st February — it comes here, as a matter of course, as soon as published, and is then published here in March (also of course); but the particulars may appear in a journal whose date is in November, or earlier of the year preceding! The editor claims the invention as his — the true inventor does not hear of it for a long time; but when he does, he points to the date on which *he* first published it, with full confidence of the public verdict being in his favour. Alas! his confidence in your ability to sustain him is sadly misplaced; for does not the advertiser of the *preceding year* contain the very same invention, in the same words, except some few *phono*-typographic alterations, in the peculiar orthography of its editor. The gentleman, professor, or what not, is clearly shown to be an unmitigated plagiarist, by the comparison of dates, which are unanswerable.

Photographic weather would be very acceptable now; but such is still a desideratum, and will most probably be till the equinox is past. ARGUS.

Correspondence.

IRON PRINTING.

To the EDITOR.

SIR,—In the last number of your Journal I notice some remarks in reply to "A Young Beginner," respecting my iron printing process. I think you are in error as to the kind of paper there recommended, for the sensitising solution entirely dissolves animal size, so that practically it is just as well to use blotting paper as any of the English papers. Canson's plain thick paper answers best in my hands.

I do not find the slightest difficulty in getting the half-tones, and the contrast between the darker and lighter parts of the picture need not be more than in a silver print from the same negative. No doubt I shall see you at the Society's meeting to-morrow, and I will then show you one or two specimens that will bear out my assertions. The tone I get by gold is better than that of my silver prints by the old sulphur bath.

If your correspondent will write to me direct, enclosing some of his failures, I will endeavour to set him to rights. — Yours, &c.

Stoke Newington, 4th April, 1859. MICHAEL HANNAFORD.

PRINTING, &c.

To the EDITOR.

SIR,—You must not think that I have altogether forgotten you. I have had a long communication on printing, &c., almost ready for you for the last two or three months, but have now abridged part of it by extracting the formulæ (which are what it appears the Journal readers care most for), appending to them some of the more essential of the observations.

In a letter in your No. 90, alluding to some remarks of mine in your London contemporary, so far was it from my intention on that occasion to accuse Mr. Hannaford of plagiarism—being, of course, quite satisfied with his admission, that he had in his published process been formulising for the benefit of the public what I had previously laid down as a principle—that had it not been necessary to abridge the article alluded to by cutting out part of the matter, *after* it was printed, Mr. Hannaford would have found a sentence to the following effect:—"It is remarkable that among many of my processes or plans which have been adopted, here or abroad, in no one instance, except that of Mr. Hannaford, has their employer or adopter considered it necessary to acknowledge their original source."

My ink process with bichromates and the vegetable salts of ferric oxide, as I mentioned to you in one of many letters (*on it* and the other ink processes) which passed between us several months ago, dates from 1854.—Yours, &c. C. J. BURNETT.

Edinburgh, March 2nd, 1852.

TONING TROUBLES.

To the EDITOR.

SIR,—Of the enclosed picture the part which should be white is very dirty, the defect being caused in the toning bath. I filtered it and had the same result. The toning bath is made with four ounces hyposulphite of soda, four grains gold salt, eight ounces water, and thirty grains nitrate of silver. I have tried Mr. Hardwich's alkaline toning, but not with success. I used to get the whites pure with the old toning formulæ. I do not know whether the annoyance may not be caused by the preparation of the albumenised paper.—Yours, &c.

Lonsdale Square, Islington. ALFRED THOMAS.

[We do not wonder at the condition of your print with such a toning bath as that given. You can never know whether it contains any gold after it has been once used, nor, in fact, what it really does contain. Its toning properties must be due principally, if not entirely, to sulphurisation. Give it up by all means. If you do not manage Hardwich's alkaline toning bath readily, employ that of Mr. F. Maxwell Lyte, which we find equally good, and can be kept ready mixed; but read his instructions carefully, and see also our reply to J. Roberts in the last number, page 88. With regard to albumenised paper, some kinds are very troublesome in the toning bath: we generally find that it is the paper and not the albumen which is in fault, as different papers prepared on the same albumen bath do not always act alike in this matter. As a rule we find thin kinds of foreign paper most liable to the defect of which you complain.—ED.]

CASES FOR PRESERVING SENSITISED PAPER.

To the EDITOR.

SIR,—You seemed interested the other night, at the meeting of the Photographic Society, with the fact of my having, for the last six or seven years, used a case for the keeping of my excited positive paper: I have, consequently, sent the case actually in use during that period for your inspection. At the time I first used it I showed it to poor Horne.

Before my long and severe illness I used to prepare my paper in Montague Street, and take a case full to Cheapside and print as opportunity offered. The simplicity of the affair prevented my "rushing into print" with a "full, true, and particular account" of, &c., but I think it involves the same principle, barring the chloride of calcium, at present in dispute between Messrs. Marion and others.—Yours, &c. P. W. FRY.

14, *Montague Street, Russell Square, 7th April*, 1859.

[We did not receive the above note until after having written the remarks that will be found in our leader, but consider the subject of sufficient interest to record the facts.—ED.]

HARDWICH'S GOLD TONING PROCESS.

To the EDITOR.

SIR,—Having been charmed with the hue of the blacks resulting from Mr. Hardwich's mode of toning by warm solution of gold, with soda and citric acid, I persevered in its use; but, to my mortification, found it gradually losing its effect, until I had only my former red and brick-dust tones.

As the paper and the chemicals were all the same as used at first (except the gold solution, which was freshly prepared every time), I was, for a long time, perfectly nonplussed at my now invariable failure after previous uniform success. Long cogitation only led to the conclusion, that the silver bath on which the paper was sensitised had become acid by frequent use. Test paper speedily confirmed the fact; so I lost no time in correcting this, by the admixture of the oxide of silver, as recommended by Mr. R W. Thomas. The bath now exhibited a slightly alkaline reaction, and upon sensitising anew, to my infinite satisfaction I had no difficulty in arriving at the purple tones for which the process is so peculiar. As many friends have complained of want of success, may it not be traced to a cause thus easy of remedy? I, therefore, advise all who find difficulty in working it, if assured that their paper be good (a perfect *sine qua non*), to examine the condition of their nitrate of silver solution.—Yours, &c.

Liverpool, April 12, 1859. C. COREY.

BOTTLED LIGHT.

To the EDITOR.

SIR,—Every photographic journal that I have seen for some time back has contained some comment on M. Nièpce de St. Victor's experiments with bottled light, and yet none have come to any real conclusion as to whether it is the action of latent light, or the action of the moisture from the water that is introduced into the tube, and the heat that is applied afterwards; for myself I have no time to try the experiment, yet I wish to know if any one has tried a yellow handbill for a negative, as I think some result might be arrived at from this. If from this an impression were obtained, I should conclude at once that the action of latent light had nothing to do with it.—Yours, &c.

April 4th, 1859. A. WHITHAM.

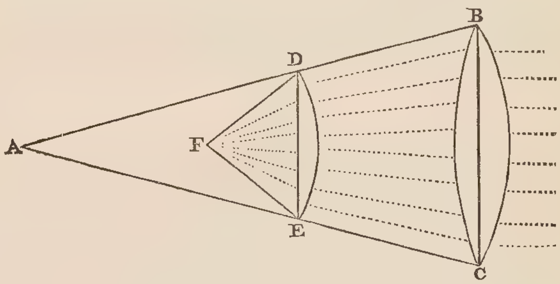
[When a gentlemen of M. Nièpce de St. Victor's standing in the scientific world puts forth a statement, however extraordinary it may at first appear, it is but reasonable to suppose that such *authority* will only be met by *positive evidence*, consequently in commenting upon the presumed discovery of a new quality of light, it is not surprising that the remarks made have been guarded and moderate. We, however, do not concur in the assertion of our correspondent, that *no real conclusion* has been put forth. We point to our last for our own opinion, while no less than two of the remaining three of our contemporaries in this country have also expressed similar sentiments.—ED.]

ON THE ILLUMINATION OF PHOTOGRAPHIC NEGATIVES BY ARTIFICIAL LIGHT.

To the EDITOR.

SIR,—It occurs to me that I can be of some farther use to your correspondent "Veritas," as regards his new difficulty.

1. As to the distance between his condensing lenses. If he draws the triangle A B C below, having the perpendicular B C to the diameter of his larger lens, and the point A at the distance of the focal length of it, then the smaller lens should be placed at such a distance as to make its diameter touch the converging lines as shown.



2. Maintaining this relation of the glasses, if he now exposes the lens B C to the parallel rays of the sun, the focus F (at which he may light a lucifer match) will show the distance from the smaller lens at which he should place his lamp for evening operations.

My own work has been done by the light of a small "fish-tail" gas-burner, and the illumination has, of course, been the least portion of my difficulties.—I am, yours, &c. H. A. S.

Aberdeen, April 2, 1859.

COMBINATION LENSES, &c.

To the EDITOR.

SIR,—Seeing that you are ever ready to afford information on points connected with the practice of photography, I venture to propose the following questions, hoping to receive answers through the medium of your valuable Journal:—

1. Will a portrait combination of lenses take *views* as *well* as an ordinary view lens?

2. Can you say whether or not the front lens of any of ——'s portrait combinations is adapted for taking views, and are the lenses manufactured by him in general very good?

3. Is there any advantage or disadvantage in using a quarter plate camera with a half plate lens?

4. Is there any advantage or disadvantage in using a *stop* between the two *back lenses* of a portrait combination?

By answering the above you will materially assist,

AN AMATEUR.

[1. Yes, if properly applied, but is much more cumbersome.—2. It is intended by the maker for use in that way, and will certainly take

pictures such as they are, but we consider none of his lenses more than second or third rate. You had better get one of a good English maker.—3. A pony would not do well for a chariot, nor a large horse for a pony chaise—though each could possibly draw the respective vehicles; so it is with the lenses.—4. A decided disadvantage.

We have been requested by the agent for the sale of Derogy's lenses to examine and report upon their qualifications. We hope to be able to do so by the time our next number is ready for press. We can state, however, at once, that we have tried the front lens of the combination alone as a landscape lens, and find it quite comes up to all that is claimed for it in this way.—Ed.]

COPYING OIL PAINTINGS, &c.

To the Editor.

Sir,—Your obliging correspondent, Mr. A. M'Nab, in his interesting paper contained in your last number, would, I have no doubt, added much to the obligation he has conferred had he given a few more details relative to difference of time of exposure between plates so coated and when simply coated with collodion, what developer he finds the best, and the time usually required for it, which I should fancy would be considerably longer than usual, but more particularly the advantages to be gained by this extra manipulation over the ordinary wet collodion, with which I conceive the plate is, after it is dry, intended to be coated and sensitised in the usual way.

1. What do you consider the best method to employ for reducing and taking a negative from an oil painting, rather dark in point of colour, namely, the best light to place it in, the kind of lens, collodion, and developer?

2. If any, and what, difference between copy and reducing the above, and a large and dark shaded positive portrait photograph?

3. What do you consider the best kind of reflector to concentrate the rays of a gas light, upon an object three inches square, and where to be procured?

4. Can Mr. Rogerson's apparatus be seen any where in London?

With thanks for former obliging replies.—Yours, &c.

London, April 4th, 1859. QUERIST.

[1. Place the painting in a *strong* light, at right angles to a window, and close to it, then proceed as if taking a portrait, using freshly mixed and sensitive collodion, and develope with an iron solution, and intensifying with gallic acid.—2. To copy of the same size the same position with regard to light will be proper, but the orthographic form of lens will be far better though much slower in action. In this case we prefer to use a syruped collodion film and long exposure: developement as before.—3. A reflector is comparatively useless for this purpose, a condensing apparatus, composed of two lenses, being very superior. See diagram in the present number.—4. We do not know.—Ed.]

COATING GLASS PLATES WITH ALBUMEN.

To the Editor.

Sir,—In the ninety-first number of *The Photographic Journal* is a paper by Mr. M'Nab, on coating glass plates for collodion pictures with albumen, which I have read over several times, but can come to no conclusion as to the meaning of the fourth paragraph of the second column, page eighty, which states that Mr. Young found that by keeping the plates became mouldy and gave foggy results—that a plate kept more than twelvemonths was tried, when the result proved corroborative of Mr. Young's assertion, viz, that it would fog. Being satisfied that this was the case, the plate was taken and a solution of protosulphate of iron was poured on it to coagulate the albumen, and that then, after washing off the iron, the result proved satisfactory.

Now, nothing is said about sensitising the plates, the paper merely speaks of plates *thus prepared*. If they were not sensitised they could not fog, and if they were, Mr. M'Nab can scarcely mean to assert that pouring protosulphate of iron on a foggy picture will clean it; nor can he mean that the iron is poured on the albumen to coagulate it, as it would have been previously covered with collodion, and if capable of being coagulated through that coating, the nitrate bath would have already done it. Perhaps you may be able to give, in a future number, the correct interpretation of Mr. M'Nab's meaning.—Yours, &c. B. JONES.

Cheltenham, 7th April, 1859.

[Mr. M'Nab's paper was upon coating glass plates with a film of albumen *previously* to their being used for taking collodion pictures upon. In mentioning to us the advantages gained thereby he stated, however, that plates prepared for some time beforehand and *stored away*, were apt to become mouldy and thus cause fogging when used to take collodion negatives or positives upon afterwards. We suggested that the mouldiness arose probably from imperfect coagulation: it is very difficult to coagulate *thin* films of albumen by heat, and advised the trial of a solution of protosulphate of iron for the purpose, previously to storing away the plates. It appears that in naming this to a friend, Mr. M'Nab determined to try whether plates that had been stored away without this treatment and had already become mouldy, could be rendered available for use by subsequently submitting them to the action of the iron solution, which was, of course, washed off, and *the plates dried* before pouring on the collodion. The immersion of the plates in the nitrate bath, after the collodion had been poured on, would not obviate fogging, although the albumen became thereby insoluble, because the mouldiness had previously come in contact with the collodion—the object of the iron solution being to *remove the mouldiness* or prevent its formation.—Ed.]

DEROGY'S LENSES.

To the Editor.

Sir,—My attention has just been called to your report of the meeting of the Manchester Photographic Society, contained in your Journal of the 15th March. You say, "Mr. Sidebotham exhibited a large lens by De Rogni," &c. From the description given, there can be no doubt that Derogy is the name intended. Your correction of this error in your next number will much oblige.—Yours, &c.

196, *Strand, London.* LLOYD CHAPMAN, Agent.

ANSWERS TO CORRESPONDENTS.

Mary P***k.—Touch the stain with a little *tincture of iodine* and let it dry, then use a strong solution of cyanide, or iodide of potassium.

J. Stevens.—See reply to "A Devonshire Man" and "Racks." We really cannot give private replies, our labour would never be at an end—as it is we have no sinecure, we assure you.

An Old Subscriber.—It would not be safe to prepare plates by Fothergill's process near a gas light, unless protected by a piece of yellow glass or calico, particularly if wanted to be kept for some time—fogging would probably otherwise ensue.

A Devonshire Man.—Yellow tammy is a woollen material like serge, and is to be had at the *upholsterers'* shops, being used by them for lining curtains, &c. It is more costly than calico, but is much more permanent in colour when exposed to light.

X., Peterborough.—In consequence of a transposition, by the printer, of the *order* of the replies in our last, you were referred to a wrong one. It should have been, "see reply to James Southwell," &c., which, as we wrote them, immediately preceded yours.

J. R.—1. It is best to take a negative direct; but, of course, if you have a positive, and wish to convert it into a negative, it may sometimes be done. 2. Tincture of iodine half a drachm, water one ounce. A good negative should exhibit all the details well *in the shadows*, when viewed by transmitted light: a positive will not do this.

T. Lee.—The yellow spot appears to be due to a small bubble of air having been allowed to remain in contact with the paper while in *one* of the baths, probably in the toning bath, though it may have been in the plain water previously used to wash away the free nitrate of silver. You will find no plan of washing after fixing better than *hanging up*, by means of the wooden clips, each proof for several minutes, between each change of water; it is very little trouble, and very efficacious.

A. F. Eden.—We have not seen the stereographs of Messrs. Ogle and Edge that we are aware of, and consequently are unable to give such hints as you desire. We believe, however, that you may attain a warm brownish-red tone by using paper strongly sized with gelatine, and not allowing the proofs to remain very long in the gold toning bath. Hollingsworth's thick paper and F. Maxwell Lyte's toning bath will most probably enable you to obtain your object.

Racks.—We have frequent inquiries as to the readiest means of providing plate boxes with grooved racks. Messrs. Smith, Beck, & Beck, the celebrated microscope makers, No. 6, Coleman Street, London, having occasion to manufacture racked boxes and drawers, for the conservation of microscopic objects, have constructed machinery for the production of the racks in mahogany. It having been suggested to them that the same sort of racks are adapted to photographic plate-boxes, they have agreed to make them in any sizes that may be required, and they will be supplied to manufacturers of plate-boxes, or amateurs, at a moderate price. These racks are beautifully cut, and it will be a great convenience to photographers to be able to obtain them readily.

Wallis.—Streaks from top to bottom of the negative may arise from one of several causes. For instance, if the plate be removed from the sensitising bath too soon, streaks will form; if it be not properly drained before putting it in the dark frame, the superfluous bath solution will run down in streaks; sometimes, also, streaks form when the developing solution is poured off carelessly—the plate should be rocked a little when performing this operation. We presume you are speaking of portraits; if so, your bath may be too acid; but *intensity* is as much dependent upon developement as upon exposure. An iron developer is very apt to be deficient in giving strength. The best remedy is to use a pyrogallic acid solution subsequently. If, after attention to the preceding, it still is deficient, we think your collodion must be in fault. Try some other kind.

*** We give in this number two additional pages of matter, notwithstanding which, several articles in type are crushed out by a press of matter of more immediate interest. Among the articles left over is an important one on Mr. Lloyd's "Dry Process," which shall appear in our next.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal, *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE PHOTOGRAPHIC JOURNAL.

No. 93, Vol. VI.—MAY 1, 1859.

On the evening following the day on which our last issue was published, the 15th ultimo, we had the pleasure of assisting (as our French neighbours phrase it) at one of the most brilliant and successful soirées of the season, where photography formed the *pièce de resistance* of the intellectual part of the entertainment, with a garnish of microscopes, gyroscopes, electro-motive engines, and other philosophical apparatus by way of side dishes.

The gathering took place at the Mansion House, in consequence of invitations from the Right Honourable the Lord Mayor and the Lady Mayoress to some of our most noted photographers, together with many distinguished members of the scientific world and private friends of the entertainers, including a goodly array of the fair sex, to meet the President (Mr. Glaisher, the celebrated meteorologist) and other officers and members of the Blackheath Photographic Society, Mr. T. Wire, the son of the Lord Mayor, being one of the Secretaries.

Judging from the animated conversation which was carried on in every direction, the pleased and eager countenances that met the eye wherever turned, and the frequent expressions of admiration and satisfaction which fell upon the ear, the entertainment provided must have been highly gratifying to every one concerned.

The number of photographs exhibited was considerable and, what is more important, of high character; in fact, many of them have before been fully noticed in these pages, consequently it will be sufficient to mention the names of the artists to indicate the class of productions.

There were contributions from Francis Bedford, M. Claudet, P. H. Delamotte, Roger Fenton, Frank Frith, Melhuish, Alfred Rosling, B. B. Turner, Williams, &c., &c., in addition to many others, chiefly members of the Blackheath Society, amongst which we recognised with pleasure some subjects taken by Mr. Wire in his trip through Kent, described in a paper published in our last volume, entitled "A Week with the Camera among the Kentish Hills," in which that gentleman sung the praises of a "dog-cart" as a *photographic* vehicle; to the justice of which praises the photographs bear ample testimony, particularly those taken at Chiddingstone, a locality apparently abounding in the picturesque.

Mr. Glaisher exhibited some highly interesting photographs from drawings of *snow crystals*, presenting very many varieties of form, as observed by him a winter or two back, when a copious fall of snow took place, in such condition as was most favourable for a microscopical investigation into the subject; the flakes not being composed of agglomerated masses, but consisting generally of regularly formed feathery crystals, perfectly symmetrical, and of great beauty,

Surrounding the collection of photographs contributed by the members of the Blackheath Society, was a beautiful series of large-sized ones representing the fronds &c., of various ferns; these, besides being of an out-of-the-way character, were further distinguished as the production of a lady follower of our art, Mrs. Glaisher.

The method of execution was by simple interposition of the actual frond itself upon a sheet of sensitised waxed-paper, which, after sufficient exposure, was developed and fixed in the usual way. This afterwards acted as a negative, from which the positives exhibited were printed, and thus a faithful *fac-simile* produced, displaying all the beauties of venation, fructification, &c.

Botanists and Naturalists generally, as might be anticipated, prefer these illustrations to all others taken by any process hitherto devised. It will be at once perceived that this is a most valuable application of photography, and one that may be followed by the many without any expensive apparatus.

The Rev. A. B. Cotton's picture of Sinai, from two negatives on waxed-paper, we notice as very effective for the particular subject delineated; indeed the waxed-paper process, in skilful hands, not unfrequently rivals collodion—for instance, some of Mr. B. B. Turner's works are such as to leave little to be desired.

We were much struck by some small pictures of Mr. Heisch's, viz., a red and a white camellia, with the bright green leaves, in a hand basket, colours most trying to the photographer to reconcile, but which under Mr. Heisch's treatment were successfully interpreted in simple light and shade. This be it remembered is no slight praise—no engraver can do more in this respect; while, as regards truthfulness of form and minutiæ of detail, of course the photographer beats the engraver hollow. There were several examples from the same subject exhibited, illustrative of Mr. Heisch's researches upon the value of employing iodides, bromides, and chlorides in something like atomic proportion; the views entertained by him being fully set forth in a paper published in our last volume. Certainly the most perfect is the proof from the negative prepared with four parts of iodide, two of bromide, and one of chloride, as a sensitising mixture.

Mr. Claudet's contribution comprised many large-sized photographic portraits coloured in oils.

Herr Pretsch displayed some of his photogalvanographic plates, together with the impressions therefrom.

M. Rejlander had a small pair of his very suggestive *morceaux*, which we believe he calls "The Two Children," the subject being taken from an old Norse legend:—

> 1st. Thus they played for hours together,
> And the dog went fast asleep.
> 2nd. So they both would sleep together,
> But the dog then watch would keep.

In both pictures the group consists of an aged grandsire, the little grandson, and the dog. In the first, the *two* children, (that is, first and second childhood) are playing at "cat's-cradle,"

the old man's countenance expressive of kindly and eager interest and lit up with a beaming smile,—the dog snugly sleeping at their feet.

In the other, the two playfellows are locked in one another's arms and having a quiet doze after their game, while the dog *wide* awake keeps a vigilant look out. The complete repose of the muscles is the point especially aimed at, and this is beautifully exemplified in the child's hand, which is particularly expressive of sleep.

And the dog! — what a famous dog he must be! — we fancy we have made his acquaintance before accompanying his master with a *camera turned into a wheelbarrow!*

Of course stereoscopes and stereoscopic subjects formed a very attractive feature in the entertainment.

As novelties in the latter branch, we have to mention a series of twenty-five, recently published by Messrs. Negretti and Zambra, of scenes and individuals of note in China, which are particularly interesting, and exhibit characteristics differing materially from the ordinary class of stereoscopic illustrations. We believe they are the productions of a photographer sent out specially by the publishers for the purpose of procuring them.

Messrs. Horne and Thornthwaite exhibited the illustrations of the moon, and also the beautiful sea-view, noticed in another column as the work of Mr. S. Fry, together with two others of a similar description to the last-named, representing the calm and the ground-swell.

Messrs. Smith and Beck were intrusted with the magnificent stereographs of the moon belonging to Mr. Warren De la Rue, enlarged by the late Mr. Robert Howlett to about twelve inches in diameter, from negatives taken by Mr. De la Rue. These were shown in the large reflecting prismatic stereoscope constructed purposely for their display, and are truly wonderful productions. Smaller copies of the ordinary stereoscopic size were also shown by the same gentlemen in their well-known achromatic stereoscopes.

Among the stereoscopic luxuries were some pillar arrangements for showing in succession a series of subjects. In one, which we believe is called "Stereoscopia," twenty or thirty paper slides are attached by their backs to endless tapes, passing over a square piece of wood, revolving on an axis upon the principle of the Jacquard loom. This arrangement does not admit of the display of transparencies.

In another a series of drawers, containing about fifty slides each, placed in racks, are so contrived that the whole, amounting to some hundreds as a total, can be viewed in succession by simply working a handle. This we believe is the result of American ingenuity; it is, we must admit, a little complicated, and rather puzzling to work correctly at first. Like the preceding, also, it is only adapted for opaque slides.

Another form, manufactured by Messrs. Negretti and Zambra, is contrived to be employed with transparencies, and this in a very ingenious manner, occupying but small space, the twenty-five Chinese views before alluded to being all mounted in one instrument. It is difficult, without the aid of diagrams, to give an idea of the method of arrangement; some notion of it may however be formed, by imagining the slides to be all arranged like the spokes of a wheel around a cylinder, but with a sort of hinge so contrived that all except the one under inspection bend out of the way.

A magnificent collection of first-class microscopes, by Powell and Lealand, Ross, Smith and Beck, and others, attracted very general admiration.

Of photographic apparatus there was a goodly display, comprising every possible necessary convenience and luxury that a photographer could desire; in fact, if any objection could have been made to such a collection, it could only have arisen from *un embarras de richesse*. Cameras of every possible (we had almost added and impossible) form—rigid and folding, portable, square, long, massive, &c., &c. — together with the thousand and one contrivances for changing plates in the field — lenses, dishes, plate-boxes, tripods, plate-holders, baths, dark slides, *cum multis aliis*.

Amongst Messrs. Horne and Thornthwaite's collection we noticed a new bellows camera, with diagonal brass stays to insure rigidity, and Powell's box stereoscopic camera.

Messrs. Burfield and Rouch had their new dark operating chamber for large plates (a developement of their registered box), in which one or two unsual essentials to comfort were apparent, viz., elbow room, and ventilation. They also exhibited a new portable camera that has some advantages.

Messrs. Murray and Heath brought out several interesting novelties in the apparatus department: in the first place there was a small deal plate box for a dozen glasses, so arranged that they rest on slips of india rubber, and are placed in V shaped racks, other slips of india rubber being fitted into the lid to prevent any vibration during transport from place to place. At the bottom of the box is a little drawer, just under the cross pieces of india rubber; this drawer being for the reception of waste blotting paper to absorb the drainings from the plates which may be put in while wet. By removing the drawer, and leaving open the lid, a free current of air passes to dry the plates. To some of these boxes, for work in the field, an additional partition is added to carry the chemicals, and the whole is thus as snug and compact as it is possible for such a thing to be. Some folding racks for draining wet plates are also natty contrivances, the principle being the same as adopted in those made by Mr. Francis—the novelty is their folding. Another well-contrived affair was a glass water-tight bath in a mahogany case, the lid being of ground-glass, and kept tight by means of a spring underneath and a vulcanized rubber pad between it and the wooden part of the lid, which also was so contrived as to be removeable without being actually separated. It is extremely simple and effective, and a matter of very great convenience to a travelling photographer, while equally efficient in the operating room.

We have been thus diffuse upon the various kinds of apparatus, because we find that our country friends especially are always eager for information relative to new and useful appliances in the mechanical department, as is indeed natural from the greater difficulty experienced by them in obtaining a sight of such matters. We therefore endeavour as much as lies in our power to make use of our eyes upon all occasions for their particular benefit, and take a note of all that strikes us as worthy of comment.

While on the subject of mechanical conveniences we may mention that we have been contriving a new folding tripod that is extremely firm and handy to use, also an effective and economical swinging back for cameras, both of which we purpose describing shortly.

PALMAM QUI MERUIT FERAT.

In our last Number, at p. 91, we published a paper read by Mr. Sidebotham at the last meeting of the Manchester Photographic Society on Micro-photography, in which that gentleman claims for Mr. Dancer the honour of having been the originator of these very minute productions.

Although we noticed the remarks made while the article was still only in manuscript, we preferred publishing the paper without comment at the time, intending in the present to make a few observations upon the statements made, not by way of detraction from Mr. Dancer's merit, but in justification of our own assertions. The production of very small photographs is so obvious a possibility as to suggest itself to many photographers without its even calling forth a remark; and, having produced them, those possessed of a microscope would as naturally examine them by its aid. We know many who did so. But this is not the point at issue.

We have ourself laid claim to having *originated* the idea of producing photographs specially *as microscopic objects*, and for

examination only by aid of the microscope, as indeed is a necessity, for they cannot be distinguished without.

The very word "micro-photograph" *we* also coined to describe them, upon the occasion of our supplying Messrs. Smith and Beck, the noted microscope makers, of Coleman Street, with some which they desired to have for sale. We find an entry made in our pocket book at the time, dated March 29th, 1854, when we furnished them with twenty-four specimens. A few of these we had exhibited some weeks previously, at the house of our friend, Mr. A. Rosling, the Treasurer of the Photographic Society, and subsequently, at the meeting of that Society on 6th April, 1854, we publicly exhibited them, as will be found recorded in the *Journal of the Photographic Society*, Vol. i., p. 194, and published on the 21st of the same month.

The dimensions of these portraits and landscapes ranged from the $\frac{1}{40}$ to the $\frac{1}{20}$ of an inch square, that is the *one-sixteen hundredth* to the *four hundredth* part of a superficial *inch*, one of them being a pretty extensive view of Paris.

Now we assert most emphatically that we never saw, or even heard of, anything of the kind having been produced, prior to our conceiving the idea and practically working it out in the early part of the month of March, 1854, nor have we ever, until we saw Mr. Sidebotham's paper the other day, heard it alleged that micro-photographs had been in existence prior to the time named.

Moreover about *twelve months subsequently* to the date quoted, Mr. Thornthwaite, to whom we had previously shown our specimens, at a soirée, at Mr. Woodward's, laid before us a copy of the monumental tablet of Sturgeon, which he alleged to have procured the production of *in consequence of what we had shown him*, and asked our opinion of its merits; to which we replied, that it was good, but the scale upon which it was taken was not comparable with those we had done, it being *very* much larger in dimension. At that time we had never heard of Mr. Dancer's name to our knowledge.

The lens employed by us was an achromatic microscopic object glass of $\frac{2}{3}$ of an inch equivalent focus, manufactured by Messrs. Smith and Beck, and the negative was placed at a distance of about three feet from it.

It may be remarked by our readers that we are making a fuss about a trifling matter, as micro-photographs can never be more than amusing curiosities; but it is a matter of some importance to us — no less than a charge against our integrity — imputing to us an attempt to claim the credit due to the ingenuity of another.

Such a charge against us appears to be involved in the article by Mr. Sidebotham, especially in the concluding paragraph; and to remain silent upon the subject would be tantamount to admitting its justice.

We do not suppose that Mr. Sidebotham or Mr. Dancer would either of them imagine that we would willingly be guilty of such turpitude; but the paper read by the former, in which it is stated that Mr. Dancer gave him some micro-photographs early in the year 1853, necessitates the inference that we had unfairly claimed credit for the latter's suggestion, unless some explanation of the discrepancy be given.

If then Mr. Dancer really did produce what are called micro-photographs at that time (1853), it was at an earlier date than our own, which was in March, 1854, as above stated; and we shall certainly be sorry should it turn out to be the fact.

We do not by this remark mean for one moment to call in question Mr. Sidebotham's veracity, but simply to request him to refer with care to his dates; and if it be found that Mr. Dancer preceded us, we shall of course withdraw our claim to having been the *first* to produce them, although we cannot concede the point of our having worked it out independently, and without any knowledge whatever of its having been done before. We purpose sending a copy of this article to Mr. Sidebotham, with a request that he will communicate it to the Manchester Photographic Society.

NOTICE OF RECENTLY PUBLISHED STEREOGRAPHS.

In our last we had occasion to bestow commendation upon some highly deserving specimens of stereographs on paper; we have now to direct attention to some printed on glass, the work of Mr. Samuel Fry, of Brighton, which are quite out of the ordinary class of these productions.

The application of photography, aided by the stereoscope, to the visible demonstration of the fact that the earth's satellite is uncontestably of a globular form, is one of more importance than at first sight appears to be the case. It is true that, by strict logical reasoning, the fact had been deduced; but, until the phenomenon had been actually brought home by the evidence of sight, the conviction thereof rested rather upon circumstantial than direct evidence; consequently, the production of photographic stereographs of the moon's surface may be regarded as the *experimentum crucis.* We believe, that to our friend, Mr. Warren de la Rue, belongs the honour of having first accomplished this feat; and, thanks to the subsequent aid of the late Mr. Robert Howlett, the public have been supplied with many copies from Mr. de la Rue's negatives.

As might have been predicted, an object of such beauty, and possessing besides so much of scientific interest, became naturally very much in demand, and several other photographers were fired with the ambition of producing equally valuable results; amongst them Mr. Samuel Fry has been eminently successful.

To those who are unacquainted with the principles of binocular vision, there will not be any thing surprising in the power of showing visibly that the moon really and truly is of a globular form, and more or less studded all over with mountainous protuberances; because they are ignorant that, in order to exhibit this, it is necessary that the pictures be taken from *two distinct points of view;* while to the unassisted eye, or by aid of a telescope, the moon's surface appears as a flat disk, but with certain parts darker than others.

Now although the inhabitants of this earth never see but one and the same side of the moon, it is a fact that owing to the relative rates of her orbital and axial motion, a small portion of her surface on opposite sides of the hemisphere next the earth are alternately rendered visible — the movement being regular and periodical, and known as the moon's *libration.* Advantage is taken of this slight change of position to procure the impressions from the requisite points of view, for of course it is immaterial whether the camera is shifted or the object itself is made to turn slightly on its axis.

In order to show the effect of an entire globe it has been thought advisable to take the moon's portrait when at the full, but in so doing it must be borne in mind that the irregularity of the surface is in a great measure lost to the eye, because the effect is precisely similar to that which occurs when we take a landscape with the sun shining directly behind our backs—we lose all the beautiful relief of shadows. It is true that by taking the impression when presenting a gibbous phase, the effect of the shadows is retained, but then a portion only of the globe is visible. Mr. Fry, being anxious to retain the advantages of both of these conditions, has in his stereographs combined a full disk with a very gibbous one, in opposite states of vibration, and the effect produced is both striking and beautiful; and though we should, if we had the choice, prefer *three* sets of illustrations, viz., those of the waxing, full, and waning moons, yet for a single one the arrangement adopted is perhaps the most satisfactory.

Accompanying the stereograph is a small pamphlet with an illustrative diagram of the moon, which imparts a fund of information, together with the names and supposed character of the more important elevations and depressions of the surface. The little pamphlet materially enhances the value and interest of the slide which it explains.

Scarcely inferior in interest to the preceding is an instantaneous picture of the sea, showing the effects of a stiff south-west breeze, in which every ripple is distinctly visible, with the white foam cresting the breaking waves, and more than all, the brilliant play of light upon the dancing spray.

We have no hesitation in pronouncing the beautiful specimen before us more satisfactory than anything of the kind that we have hitherto seen. The perfectly liquid appearance of the water, the transparency of the spray, the four vessels towards the horizon, and the graceful curl of the wave, together with the general brilliancy of the whole, unite to bring vividly before the mind the

pleasurable sensation of the bracing effects of inhaling the sea breezes. In fact one never wearies of looking at this specimen, and while viewing it we almost fancy we hear the rush of the surging waters and smell their briny savour.

We strongly advise those having stereoscopes to indulge in the luxury of a mental visit to the sea-side.

MR. F. G. LLOYD'S DRY PROCESS.

Mr. Alfred Keene having made his first appearance this season in your April 1st number, and published (for I dare not say "positively the last" time) his mode of manipulation in Fothergill's process, I beg to call your attention to, in my opinion, a much simpler and more efficacious method of proceeding, by which quite as good results are obtainable, with less trouble, considerably less exposure, and a less protracted developement. This improved process is the invention of Mr. F. Giesler Lloyd, of Belsize, Hampstead, and it so completely supersedes the troublesome manipulation usually prescribed in Fothergill's, that I suppose that no one who has tried it once will go back to the other.

Albumen — prepare thus: To each ounce of albumen add an ounce of water and three minims of liquor ammoniæ. Beat up in the usual way, allow to settle, and filter through sponge. Preserve in a stoppered bottle with camphor. For use, one ounce is diluted with nineteen ounces of water, to make up a pint.

After removing the plate from the nitrate bath drain for half a minute, rest the plate on blotting paper, and wipe the back dry. Place it in a *well-bath*, containing two ounces of the dilute albumen, and lower the bath suddenly to cover the surface of the plate at once. Move the bath, so that the albumen may flow backwards and forwards for about two minutes, or until the albumen wash becomes milky and does not get more so; then pour it off, supply its place with water, and agitate: pour off the water, take out the plate with a silver hook, and wash it well under a tap; finally, rinse with distilled water and set up to dry. When surface dry, place the plate before a red fire, or complete the drying over a spirit lamp.

Exposure — The time is short, the plates being very sensitive.

Develope with pyrogallic acid and citric acid, one and a-half grains of the former and three-fourths of a grain of the latter to the ounce of water. Neither alcohol nor acetic acid are necessary.

First wash the plate in distilled water and place on a levelling-stand. To every two drachms of developing solution add three drops of a thirty-grain solution of nitrate of silver. After moving the solution over the plate two or three times, let it remain still until all the details appear; then pour off, and add nitrate of silver until sufficient intensity has been obtained.

Should the developer become much decomposed, mix a fresh quantity with more nitrate.

Fix with cyanide of potassium, five or six grains to the ounce.

Such is this process, simple, easy, and intelligible, and I recommend a trial of it to all those of your readers who wish to obtain excellent results with the least amount of trouble.

Although I have not yet tried developing with protosulphate of iron and citric acid, as detailed in your last number, page 78, I think it applicable to the above process, and that it would reduce the time of exposure by one-third. The solution given by you seems to me rather too strong, and I would recommend trial of a weaker one, say ten grains protosulphate of iron, and three-quarters of a grain of citric acid to the ounce of water. Two drachms of this and two drops of nitrate of silver solution would be sufficient for a stereoscopic plate.

Preliminary Coating — Allow me to thank Mr. MacNab for his interesting paper (supra, p. 80) on the coating of glass plates with albumen, prior to using them for the wet process. They will be found equally useful for every dry process in which collodion is employed. I am glad to see that the importance of this method is beginning to be recognised. It was first announced by the Rev. W. Law, of Marston, near Rugby, in two letters addressed by him to the *Journal of the Photographic Society*, October, 1854, and was almost simultaneously, in the autumn of that year, put into practice by Mr. R. Barnes, and subsequently detailed in his pamphlet on the "Dry Collodion Process." Those who have seen what can be done with both wet and dry collodion on albumenised plates, in Mr. Barnes's hands, may be well satisfied with such results.

A paper has recently been published by Mr. Nevile, which may be termed a modification of Mr. Barnes's process for dry plates. He simply coats the plates with a mixture of half albumen and half water, and dries them; but I should prefer Mr. MacNab's formula. Mr. Nevile uses an old collodion with a rotten film in preference to a newer one, and sensitises in the ordinary nitrate bath, letting the plate remain double the usual time. After taking it out he washes it for half a minute in a bath of water made slightly acid with citric acid; this has the same effect as sensitising in an aceto-nitrate bath. The plate is then set up to dry, and the drying may be completed by artificial heat. After exposure the plate is again put into the citric acid water to moisten the film, and is developed with a solution of pyrogallic and citric acids and a few drops of silver, in the way indicated above. The developement is not longer than with wet collodion. Wash and fix with hyposulphite of soda. The plates by this method are not easily spoiled by over-exposure. If they are to be exposed in one or two days after preparation no preservative solution need be used, but if the plates are required to be kept for some time before exposure, give them a coating of dilute albumen, and drain off before they are dried.

I think it of importance to direct the attention of your readers to these two processes, as they are both closely related, and I shall be happy to find that they will not only be practised but improved upon. If Mr. Barnes would give us the benefit of his experience in the latter mode of operating, I am sure I shall not be the only person who will thank him for imparting information on a subject which he has made peculiarly his own, as he was unquestionably an independent inventor of the dry collodion process on albumenised plates, and the first to point out the necessity of employing a collodion giving a structureless film for the dry process

AN AMATEUR.

SILVER PRINTING PROCESSES,

Including Salting, Sensitising, Toning, Fixing, and Testing Baths.

By C. J. Burnett.

(Continued from page 90.)

No. 9*.

Hydrofluoric-ammonio-nitrate bath made on the same principle as those already described, but by adding *hydrofluoric acid* or fluoride of ammonium* (or potassium) to an ammonio-nitrate bath.

No. 10.

Fluo-nitrate of silver bath, formed by adding fluoride of ammonium (of potasium or of sodium) to a neutral nitrate of silver bath. This bath is specially intended for sensitising paper salted according to formulæ 2, 3, 4, 8, 9, 10, and allied formulæ.†

No. 11.

Benzoate of silver being to a considerable extent soluble, we may form a neutral benzoic-nitrate bath by adding benzoate of *soda* (or of ammonia) to a neutral nitrate of silver bath.‡ Intended for salting chloride, chloro-bromide, and pure bromide-salted papers. This bath should also be tried with albumenised papers.

Nos. 12, 13, 14, 15, 16, 17.

An ammonio-nitrate bath, with the addition of, in the first instance, a small quantity of hydrofluoric acid or fluoride, and then (12) benzoic acid (or a benzoate) to saturation, and similar, but with (13) citric, (14) formic, (15) oxalic, (16) succinic, (17) tartaric, or other acid instead of benzoic.

Nos. 18, 19, 20.

Baths, by adding (18) benzoate of soda (or ammonia), or (19) formiate, or of (20) malate soda to a neutral nitrate bath, along with fluoride of ammonium or potassium.

N.B.—Should any one ask me which of all the various formulæ yet published I would recommend for one who has not leisure for trying, or does not care about trying, a variety of processes, but wishes to set to work with *one* thoroughly good and reliable-on

* Hydrofluoric acid, unless very dilute, must be cautiously handled. The bi-fluoride of ammonium is a convenient salt.

N.B.—All baths or solutions containing *fluorides* or hydrofluoric acid should be used *only in gutta percha vessels.* Can a neglect of this precaution have any thing to do with the discrepancies of opinion, as to advantages of the introduction of fluorides in negative processes?

† Though I have got good pictures from papers containing fluorides, I do not yet undertake to pronounce whether there is any thing of importance gained by their use in printing, but give *these* sensitising baths (*i.e.*, 9 and 10 and 12-20) containing them merely to show what I believe to be, on principle, the best way of introducing them, if they are to be used.

N.B.—I have not yet been able to get the fluorides to *take the place* of chlorides, bromides, or iodides (fluorine seeming, at least in this combination, much less readily allotropisable than its allies?). Had it been capable of replacing them, the fluorides of silver being very easily *soluble*, we might have been able to simplify our operations by dispensing altogether with separate salting bath, and the fixing without hyposulphite would also have been *greatly* expedited.

‡ The citrate tartrate, &c., and other salts which are nearly insoluble in water (even more than the benzoate), being yet soluble to some extent in a nitrate bath, might be also introduced in this same way; also the malates and formiates.

process, I think I might venture to reply,—Take chloro-bromide paper,* salted by my formula A, No. 1, or else, according to tone, &c. wished, common chloride of ammonium or sodium salted paper,† and sensitise it with a bath prepared according to my sensitising formulæ B, No. 1 or 2, by the addition of *citric* or benzoic acid to the old ammonio-nitrate bath (or you may neutralise partly with each acid). You will then have a paper which will give you *fully* as good results, as to tone and adequate representation of the negative, as any now in use, and which, especially when prepared with citric acid, keeps much better in the sensitive condition than the old ammonio-nitrate papers will do. You have all, and I think more than all, the advantages, as to the results obtained, of the old ammonio-nitrate paper, without the liability to discoloration which has stood so much in the way of its more extended use. Those, however, who prefer the old plain neutral nitrate bath, should try it on papers salted according to salting formulæ A, 2, 3, 8 (or some of the others containing salts of vegetable acids). Benzoate and citrate of soda (or tartrate of ammonia) together, instead of either of the two alone, answer very well in mixture along with the chloride (or chloro-bromide). The mixtures of these vegetable salts I would recommend for use in albumenising papers for those who must have albumenised papers, though for my own part, except for stereoscopic prints, I, as a general rule, dislike albumen.

Photographers will take note that the materials I have *specially* recommended are all quite accessible.‡ Benzoic acid is obtainable at any chemist's shop, and should not cost more than 1s. 6d. per ounce; benzoate of soda can either be purchased or easily made from the acid; citrate of soda is purchasable or easily made; tartrate of ammonia easily made, or Rochelle salt purchasable at 1d. per ounce; also that oxalate of ammonia is cheaply purchasable; formiate of soda and succinic acid, or succinate of ammonia, are to be got at some of the principal chemical shops; fluorides of potassium and hydrofluoric acid ditto; malic, racemic, and meconic acids are occasionally to be met with; fumaric acid and its salts must be made, and I have not yet got them tried in the *pure* state.

(To be continued.)

POSITIVE PRINTING.—PRESERVATION OF SENSITISED PAPER.

The researches of Messrs. Davanne and Girard have now extended to the causes of the discolouration of sensitised paper, and to the means of effectually obviating them. Paper prepared with nitrate of silver, it is well known, will not keep many hours; it becomes discoloured and of a *scorched* appearance, while it loses its sensitiveness, and becomes altogether unfit for producing good positives. This deterioration takes place within a period of time that varies with the state of the weather and with the quality of the paper: it is most rapid in a warm moist atmosphere, but proceeds much more slowly in one that is cold and dry. Papers prepared by other methods, as with the chromates for example, do not undergo this deterioration; but the employment of paper prepared with the chromates would upset all our present *modus operandi*, while the proofs obtained would be vastly inferior to those yielded by nitrate of silver.

In tracing the cause of this deterioration in sensitised paper, we must remember that the surface is formed by the mixture of two very distinct bodies, insoluble chloride of silver, and soluble nitrate of silver in great excess, which remains on the surface in a free state—they are both indispensable to the obtaining of a good proof, with all the half tones and relief so much coveted by artistic photographers. Upon examination, it was found that the free nitrate is the cause of the discolouration of the paper; for upon taking a sheet of silvered paper and dividing it in two parts, and washing one to remove all the free nitrate, so that nothing remained on the paper but the insoluble chloride, this portion underwent no alteration when kept in the dark, while the other portion became rapidly discoloured, and at the expiration of three or four days was quite unfit for use. This preservative power of chloride of silver is permanent, whatever may be the quantity in the paper.

It would therefore be easy to prepare a silvered paper, that could be kept in good condition for a long time, by simply freeing it from the excess of nitrate of silver, but in that case the paper would be unfit for photographic purposes. The deterioration of positive paper in the dark is evidently due to the action of the free nitrate of silver upon the organic substance of the paper: this deterioration may be promoted by secondary causes, such as great concentration of the nitrate, or the prolonging of the time the paper is allowed to float on the silver solution, or as the sizing may have a greater or lesser tendency to combine with the nitrate of silver; every experiment however tends to prove, that the free nitrate is the sole cause of the discolouration of the sensitive paper.

It has been observed by every one, that sensitised paper becomes darker on the back than on the face, which may be easily explained, from the fact, that on the surface of the paper the free nitrate is mixed with chloride of silver, which takes no part in producing the deterioration, while the back is charged with free nitrate, which penetrates by capillary attraction.

The mode of manufacturing the paper, and the nature of its sizing, have also an influence on the deterioration of the sensitised paper. English papers, strongly sized with gelatine, undergo less change than papers of continental make, amongst which those that contain the least sizing, are the most subject to change. The more sizing there is in the paper, the less nitrate is absorbed by capillary attraction. This fact induces the belief, that the salts of alumina, which possess the property of inducing impermeability in tissues, may, when judiciously employed, communicate to photographic paper a conservative property. This is proved by experiment. Positive papers salted with chloride of sodium, to which one per cent. of alum is added, preserve their integrity much longer than when prepared in the usual manner.

In seeking to discover the law governing the alteration of sensitised paper, and taking as a guide the changes in ozonized paper when exposed to humidity, we may conclude that moisture plays a very important part in the alteration sensitised papers undergo. When prepared paper is kept in a state of absolute dryness, it retains for an indefinite time all its original value and properties. Pieces of positive paper of the most diverse kind have been suspended, in the dark, in jars hermetically sealed, containing hygrometric substances, such as chloride of calcium, carbonate of potass, &c.; at the expiration of three months the paper had undergone no alteration, not the slightest discolouration was apparent, while the other portions of the same papers, kept in portfolios, were stained. Thus it appears that when sensitised paper is preserved in a completely dry state, in an atmosphere also quite dry, it undergoes no deterioration, but is at the end of three months as fit for use as at first.

Boxes may be easily constructed in which this condition is fulfilled. At the bottom is placed the hygrometric substance, covered with a frame fitting tightly, upon which a piece of fine linen is strained; above, but not in contact with the linen, the sensitised papers may be kept. The top of the cover may be lined with some yielding substance, into which the interior of the box should press tightly, so as to preclude the admission of air.

ON PRINTING GLASS TRANSPARENCIES.

By T. H. Nevill and James Dorrington.

[Read at the Meeting of the Manchester Photographic Society, by Mr. Dorrington.]

(Concluded from page 192.)

These earlier suggestions appear, however, to have been nearly overlooked, for they have never been extensively employed by either amateurs or professionals, so far as is known. In his first experiment with the albumen, prior to applying the collodion, Mr. Nevill carried out Mr. George Nevile's suggestions literally, washing the plates in water slightly acidulated with citric acid. The result, however, was a failure, so far as the picture was concerned; but the tenacity of the film was found perfect, and thus one great difficulty was in a fair way of being overcome.

The next experiments were made by combining certain parts of Mr. George Nevile's process with our old favourite—the raspberry syrup. The plates were first coated with albumen; then, after being dried, were covered with collodion in the usual way, and after sensitising were treated exactly according to the formula framed by Mr. Sisson, for the raspberry syrup. From plates so

* Paper salted with bromide alone also deserves a trial. I have got not bad results on it when sensitised with these baths. A bromide and benzoate salted paper, sensitised with nitrate of silver, also gives good proofs.

† Marion's or Canson's salted, as sold, gives capital tones.

‡ I might have varied the manufacture of some of the sensitising baths, had I not been so anxious to attend to this, *e.g* by., recommending the pure solutions of citrate, benzoate, succinate, and other allied salts of silver in ammonia, and discarding the nitrate altogether. I might also have recommended the double salts, generally freely soluble and easily crystallisable, (and which might readily be prepared for sale in crystals, if in demand) which are formed by their vegetable acids in combination with ammonia and silver-oxide together. Both these classes of baths will yield good prints, and are highly deserving of the photographer's attention; though with the exception, perhaps, of the acetate and carbonate, not generally articles of commerce, the organic acid salts are in most cases so readily obtainable by double decomposition and precipitation in the case of sparingly soluble ones, as tartrate and citrate, or by solution of carbonate or oxide of silver in the acid in the case of more soluble ones, that there is, even now, not much of an obstacle in the photographers way.

prepared the result was at times most satisfactory, as will seem by the specimens now upon the table, numbered 1, 2, 3, and 4.

But it was found that there was very frequently a tendency to become dirty in the developement, as exhibited in pictures No. 5 and 6, for which no satisfactory reason could be found, for this tendency was very irregular. In the most carefully prepared plates, the dirty deposit sometimes made its appearance immediately on the application of the developing solution, and at other times only about the time that the developement was on the point of completion. In every case, being within the film, it was irremovable, as exemplified in No. 5 plate, where an attempt was made to remove it.

It was at this stage of his later experiments—the earlier ones of which he had already made known to me, from time to time, as they were being carried on—that Mr. Nevill showed me what results he had obtained, and asked me if I could suggest any means of removing the difficulty he had met with. My first idea was that the dirt was owing to the use of common water, not distilled, and I repeated his experiments, carefully preparing the plates with distilled water. The result was the same. It then occurred to me to try gelatine in the place of albumen; and, accordingly, I prepared some gelatine from the formula given by Dr. Hill Norris, in December, 1856, through the *Journal of the Photographic Society*. On trying the first plates so prepared I was delighted with the result:—it was entirely successful with each of two plates so prepared, whilst several other combinations which I had made at the same time were defective in one respect or other, and were at once abandoned.

The Process now Employed.

Having been applied to by many parties for the details of the process, which has evidently not been fully understood, as may be gathered from paragraphs in the various journals, I now proceed to give them, at the risk of rendering this paper unduly long, and of the repetition being thought tedious:—

First, then, to prepare the gelatine, take

Nelson's Patent Gelatine	60 grains.
Distilled water	7 ounces.
Alcohol	1 ounce.

Soak the gelatine in about one ounce of the water, then dissolve it completely by heat. When dissolved, and nearly cool, add the remaining six ounces of water, and the alcohol; also a small quantity (half a teaspoonful, or less, is sufficient) of albumen, that has been beaten up. Heat the whole to boiling temperature, before which the spirit causes the albumen to coagulate. Allow it to settle in a warm place, after which filter carefully. When properly prepared, the gelatine solution is perfectly bright and clear.

With this, whilst warm, coat the plates as with collodion, taking care to effect this by once pouring on and off. Dry by rearing on one corner. If the plates are a little damp, they are the more easily coated. A large quantity of plates may be gelatined at a time, and so kept till wanted for use.

Before coating with collodion, warm the plates at the fire, so as to ensure the surface of the gelatine being quite dry; and when cool, proceed as with the ordinary collodion process, and sensitise in a neutral bath. I use thirty-five grains of nitrate of silver to the ounce of water. Any good collodion, positive or negative, seems to answer; but the plates on the table are mostly taken with Keene's collodion, as prepared for Fothergill's process. A very old collodion, in some cases, gives an opalescent film, which it is as well to avoid, although it disappears when varnished. Collodions prepared with resin are still more objectionable in the same respect.

The plate, on removal from the bath, is passed into a dish of distilled water, and left there until another plate is ready to take its place, when it is passed into a second dish of water, and afterwards to a third, by which time it has received the necessary amount of washing.

It is then transferred into a dish containing the raspberry syrup, diluted with six times its bulk of water, in which dish it remains until the fifth plate is ready to be taken from the bath.

When taken out of the syrup dish, the plates should be placed in one corner, and left to dry naturally, in a dark room of course.

The Printing.

Before using these plates it is perhaps as well to warm them slightly at a dull fire, so as to prevent any chance of the film adhering to the negative, although I have seldom found this necessary in practice; for, whilst the back of the plate, unless cleaned, is often very tacky, the syrup on the collodion side seems generally to get almost entirely absorbed into the film, especially after the plates have been prepared for a few days.

After printing I first moisten the surface with water, and then develope with a solution—

Pyrogallic acid	2 grains,
Glac. acetic acid	20 minims,
Water	1 ounce,

to which a little alcohol may be added if preferred. Theoretically, perhaps, no alcohol should be used; but I find, by experience, that the developing solution flows more readily when a small quantity of alcohol is added. To one and a-half or two drachms of this add three or four grains of a solution of nitrate of silver, forty grains to the ounce of water, and pour this on and off over the moistened plate. The silver should always be added to the developing solution before the latter is poured over the plate. In a few minutes the picture makes its appearance, and the developement may be carried on, generally with the same solution, until sufficient intensity is obtained. Fix with cyanide of potassium, or with hyposulphite of soda. Wash well, and dry. If there should be any deposit of dirt, which in this process can only arise from careless developement, or from a bath being out of order, it will be found to be merely on the surface, and can readily be removed entirely, by again wetting the plate, and rubbing it whilst under the tap with cotton wool or with the finger. It is, however, imperative that the plate be well dried before attempting the cleaning away of dirty deposit after, or during the course of, developement, otherwise the film will rub off; although, after drying, it will bear any reasonable amount of rubbing.

It is not necessary to varnish these pictures before mounting. They are not in any way improved by a varnish, which often, in fact, brings only defects, from spots of dust or uneven flow.

It will be seen, from this paper, that we advance NO claims to any new discovery. We have simply followed out and combined ideas previously published; and before attaining a process sufficiently successful to be worthy of communication to this society, have patiently worked our way with partial successes, but far more numerous failures, the trouble of which others who may be disposed to follow in our steps may now be saved. We shall feel amply repaid for our own pains and labour if the process which I have now detailed prove as successful in the hands of others as it now almost invariably does in our own; and we are glad to be in some measure able to reciprocate, by this communication, the many useful hints and suggestions that we have from time to time received from our fellow-members in particular, as also from the generally free communications of our brother photographers at large—an easy, simple, and expeditious method of printing glass transparencies having long been a desideratum.

PRODUCTS RESULTING FROM THE ACTION OF BROMINE AND CHLORINE UPON WOOD SPIRIT.

By M. S. Cloez.

I. When bromine is gradually added to pure methylated alcohol, an energetic reaction takes place, accompanied with a considerable elevation of temperature. The wood-spirit employed in this operation must be put into a tubulated retort, and the bromine introduced through a long tube reaching to the bottom.

The acid vapours resulting from the reaction pass over into a tubular receiver surrounded with ice; one portion of the vapours condense into a liquid acid, containing unaltered wood-spirit and hydrobromic methyl-ether in solution; the rest passes into the atmosphere in the state of hydrobromic ether, mingled with a very irritating volatile substance which excites tears.

About ten or twelve parts of bromine are employed for one part by weight of wood-spirit; when the reaction is complete, the liquid in the retort separates into two portions: the lightest is acid, being a saturated aqueous solution of hydrobromic acid; the other, more dense, constitutes the principal product of the operation; it is an oily liquid, of an amber colour, which soon becomes a solid mass formed of colourless crystals, when exposed to the air after many washings with distilled water.

The crystals formed remain impregnated with the volatile irritating substance already mentioned. They are purified by being pressed between bibulous paper, so as to completely remove the liquid that soils them; they are next treated with warm absolute alcohol: the filtered solution deposits, upon cooling, colourless prismatic crystals, similar to those of nitrate of potassa.

The centesimal composition of this product is the same as that of bromal, resulting from the action of bromine upon the ordinary alcohol; but as all its physical properties are different, it must be designated by a special name; that which at the same time ex-

presses the written formula of the body and its chemical function, is —*parabromalide.*

The formula $C^4 H Br^3 O^2$, or one of its multiples, represents the composition of parabromalide; it is deduced from several analyses made upon products obtained at various operations.

The following equation shows that parabromalide produced from bromine and wood-spirit arises simply from an elemination of water and hydrobromic acid:—

$$2 (C^2 H^4 O^2) + 8 Br = C^4 H Br^3 O^2 + 2 HO + 5 H Br.$$

The density of parabromalide is 3·107; it melts at 67° C.; when distilled, it is decomposed. At about 200° C. it decomposes into bromine and hydrobromic acid; elevation of temperature destroys it completely, forming a mass of carbon in the retort. It is completely insoluble in water; its best solvent is concentrated alcohol; chloroform dissolves a large quantity; it is decomposed by a dilute aqueous solution of potash into formiate and bromoform, in the same manner as its isomeric body bromal.

Cold alcoholic-ammonia solution acts upon parabromalide nearly like potash; but when the operation is conducted in closed tubes, at a temperature of 100° C., the reaction is more complex; for, besides formiate of ammonia, we find in the liquor the products resulting from the action of alcoholic ammonia upon bromoform, and a brown powder remains in suspension, which appears to be impure cyanhydrine.

II. The action of chlorine upon wood-spirit has been studied by several chemists. In examining this subject anew, I have ascertained that chlorine acts in exactly the same manner as bromine: the principal product of the reaction is a body isomeric with chloral—*parachloralide;* it separates from the water, and gives out much hydrochloric acid, mingled with chloride of methyl. The wood-spirit subjected to chlorine must be in the greatest possible state of purity, and absolutely anhydrous, obtained by repeated rectification upon powdered quick-lime.

The chlorine is immediately absorbed by methylated alcohol; the action is sometimes so energetic as to occasion explosions. It is necessary to operate in diffused light: at first the apparatus must be properly cooled; but towards the end of the operation the retort must be warmed, so as to distil the product in a current of chlorine.

The oily liquid saturated with chlorine is mixed with its volume of concentrated sulphuric acid. After twenty-four hours it is distilled upon massicot in a current of dried carbonic acid.

Parachloralide is a liquid similar to chloral; its density is 1·5765 at 14° C. It boils at 182° C., and distils almost without residue. It has a suffocating odour, similar to that of perchloroformic ether; its insolubility in water permits of its being perfectly distinguished from chloral, from which it also differs in its boiling point being almost double. With the fixed alcalis and alcoholic ammonia it behaves exactly like parabromalide.

The formula of parachloralide ($C^4 H Cl^3 O^2$) probably represents only two volumes of vapour; so it is with the formula of parabromalide, which, if the hypothesis be true, must be doubled. This is a point to be investigated. The determination of the density of the vapour of parachloralide, made at the temperature of 265° C., has given but very unsatisfactory results; for the liquid in the receiver undergoes alteration in becoming coloured and producing a little hydrochloric acid gas.

Between chloral and parachloralide, and between bromal and parabromalide, there must exist the same relation as between ordinary aldehyde and its isomeric modifications, paraldehyde, metaldehyde, and etaldehyde; unfortunately, the equivalent of these products has not been definitely ascertained, and we cannot derive any conclusions from these relations that will establish the equivalent of the two new bodies described above.

COLLODION FROM CELLULOSE.

By M. D. Van Monckhoven.

The discovery of M. Schweitzer, recently detailed in this Journal (page 80), of a new solvent for cellulose, has excited much interest among photographers, in the hope that a new collodion would be obtained, in which cellulose would replace gun-cotton. The experiments of an eminent scientific photographer, M. Van Monckhoven, lead us to hope that this desirable result is arrived at. He dissolved recently-precipitated oxide of silver in the cupro-ammoniacal solution of cellulose, and spreading the liquid on a glass plate, put it when dry into dilute hydriodic or hydrobromic acid. A white layer of iodide or bromide of silver is formed, but it was impossible to obtain a clear and transparent image upon it. A continuous layer of reduced silver is formed beneath the layer of cellulose, and the superficial image is lost. The same results attended the employment of the ammoniacal deuto-bromide of copper (2 Cu. Br, 5 N H^3) and the ammoniacal iodide 2 (N H^2), Cu. I, 3 H O, a brown veil of metallic silver always formed beneath the image. These results are named to warn others against undertaking useless experiments.

The methods that succeeded are as follows:—

The ammoniacal solution of deutoxide of copper is prepared either by saturating concentrated ammonia by oxide of copper recently prepared, or in employing the method of M. Pelygot, which is much the simplest.* When the solid impurities are quite settled, dissolve cotton in the liquid in the proportion of eighty-five grains to the pint. A thick liquid results, which is gradually diluted with water, until all the cotton is dissolved. Then a concentrated solution of iodide of potassium is added, so that thirty five ounces of the solution of oxide of cupro-ammonium will contain from seventy-five to one hundred-and-fifty grains of iodide. It is this mixture with which the glass plates are coated.

All the beauty of the proof will depend upon the preparation of the cupro-ammoniacal liquor, which must be thick, so that it flows slowly over the glass plate, and it must be quite transparent when dry. If the fluid is too thin the image will be superficial, without intensity, and will be washed away under a stream of water.

The ammoniacal solution, when poured on the glass, should spread itself evenly; it evaporates slowly; when the excess of the liquid is drained off, the plate is set against the wall. Two modes of operating next present themselves.

1st. After the plate has been allowed to evaporate a few minutes only, the coating becomes opaline, and an excess of liquid falls to the lower edge of the glass, which must be removed by a piece of tissue paper; the plate is then immersed in the nitrate of silver bath, to which recently-precipitated acetate of silver and acetic acid are added. The coating becomes white, as in the usual method, by the iodide of silver formed; it is then exposed in the camera, and afterwards developed as in the ordinary process.

2nd. If, on the other hand, the plate is allowed to become quite dry, the ammonia being quite eliminated by evaporation, the ordinary reaction of alkaline iodides upon the salts of the deutoxide of copper takes place; that is, protiodide of copper (Cu. I) is formed in the layer of cellulose, and iodine on the surface. Such a plate becomes red when dry. Plunged in the nitrate of silver bath, it yields a superficial picture, which the slightest washing removes, and metallic silver is formed under the image, through the presence of proto-iodide of copper. But as this method will be preferred by photographers on account of its simplicity, a remedy for its inconveniences may be found by passing the plate into a bath of anhydrous alcohol, into which a current of dry ammoniacal gas has been driven. The free iodine is transformed into iodide of ammonium, and aldehyde is formed:—

$$2 I + 2 NH^3 + C^4 H^6 O^2 = 2 NH^4 I + C^4 H^4 O^2$$

The plate becomes white after an immersion of a few seconds. On removing it from the bath, it must be agitated in the air, so as to remove the excess of ammonia by evaporation; then plunged, humid as it is, into the nitrate of silver bath; afterwards proceed as in the ordinary method. In this way may be obtained proofs of very fine quality, transparent, and free from spots.

It is certain that cellulose may supersede gun-cotton in collodion, to the great gain to photography in simplicity, economy, and excellent results.

ON THE UTILIZATION OF NITRATE OF SILVER BATH.

It is frequently desirable to make use of old nitrate of silver baths, by concentrating them to a suitable strength for positive printing; but they are seldom found available without some special treatment. One method, suggested by Mr. Eliot, is as follows:— Evaporate the bath solution till it is of the strength of fifty or sixty grains to the ounce; then add citric acid, in solution, of any strength, until precipitation ceases; then add ammonia, until the reddened litmus is restored to its proper colour; filter, and afterwards add nitric acid, two drops to the pint. When the citric acid is first added, a precipitate is formed, which ceases after a small amount has been added, and is not increased by further addition of acid. The solution, when filtered, furnishes rich purple tones to paper floated upon it, when the gold bath is very active; if it is not so, there is great difficulty in subduing the red colour imparted by the free citric acid. When *aqua ammonia* is added, to effect neutralization, a further precipitation of a light flocculent deposit

* By digesting copper *turnings* in a measured quantity of strong ammonia.

takes place, which appears to fill the bottle, but, when filtered out, is very little. The papers now floated upon the solution, print and tone to a dense neutral black, and take the gold readily. When two drops of nitric acid are added to the solution, it works as well as can be wished. The precipitates appear to be, in the first instance, iodide of silver—in the second, citrate of silver.

ON A MODIFICATION OF THE META-GELATINE PROCESS.

By D. W. Hill.

[Read at the Meeting of the North London Photographic Association, April 27, 1859.]

Not having been as successful as I could wish in preparing *large* plates by Fothergill's process, I have, for some time, used a modification of Maxwell Lyte's meta-gelatine, which I prepare as follows:

Soak one-and-a-half ounces of Nelson's gelatine in eleven ounces of distilled water for a few hours; then boil till dissolved, stirring constantly; then add two drachms of sulphuric acid in two ounces of distilled water, and boil gently for a quarter of an hour—allow it to get cold (I leave it all night); then boil again for a quarter of an hour, and neutralise the acid with powdered chalk; filter while hot; add one ounce alcohol, and make up the whole quantity to eighteen ounces—filter till quite clear.

Some prefer adding the white of an egg to the solution before diluting it, and boiling till it coagulates, when it runs through the filter like water.

After sensitising the plate, dip it in a gutta percha bath, containing moderately pure drinking (new river) water, till the water runs evenly over it; drain, and wipe the back with sponge; then pour on the meta-gelatine along the upper edge, and let it flow in an even wave over the plate—let half run off into the waste dish, and pour the remainder into the measure for the second application; then, with some kind of water, wash it off thoroughly *à la Fothergill*, and dry the plates before a fire. I find the picture developes more evenly, and is much less liable to stain. I have used it for 12×10 inch plates. The exposure with Ross's 9×7 inch lens, ⅜-inch stop, seven or eight minutes. With ½-inch stop, developing with iron, two minutes. I use the residues of all sorts of collodion, which has been accumulating for years.

I prefer bringing out the picture with iron, and finishing with pyrogallic and citric acids.

By using old collodion for cleaning the glass and polishing *thoroughly*, I never get a blister, and the plate will bear any amount of washing, though it is a good idea to cover the mouth of the tap with muslin, which prevents the water coming with too much force.

The method of making the meta-gelatine is nearly the same as M. Lyte's first formula; but he recommended the addition of honey and water, which, I think, only increases the risk of failure.

We extract the following, at the instigation of an esteemed correspondent, who thinks well of the hints thrown out, although some of the assertions made do not at all square with our own opinions. We are always, however, glad to let *both* sides of the question be examined by our readers, conceiving that it is the only way of arriving at sound conclusions:—

ADAPTATION OF THE DEVELOPING.

The strength of the bath is all the time changing, and the developing that will work well to-day may not work at all to-morrow. If you cannot procure satisfactory delineations, weaken the developer with water until they suit you. I adapt my developing every day or two, and can tell in an instant what change need be made. Make your collodion and bath by the formulæ, and then dont tamper with them, as any desired result may be produced by changing the strength of the developing. Too strong developing destroys the delineations, too weak gives smutty lights.

After being in use some weeks there will be an accumulation of alcohol in the bath when this collodion is used, so that the developer will not flow over it and develope the negative evenly. This "crawling" of the developer can only be remedied by evaporating the alcohol from the bath; it can be done by placing the solution in a strong open-mouthed bottle: place the bottle in an iron or earthen vessel containing water, and heat it gradually until the alcohol is evaporated. This operation is attended with some little trouble, but after becoming accustomed to it, I find this process has many advantages, which repay more than ten times over this one drawback on its practicability. The alcohol can be evaporated after the day's work, and the bath will be ready for use in the morning, after filtering. Alcohol should never be used in developing, as it precipitates the iron out of the solution, and is the cause of many of the holes in the skies so generally complained of.—*From an Article in "Humphrey's Journal" (American), by F. B. Gage.*

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

The usual meeting of this Association was held on Wednesday last, the 27th ultimo, at the Myddleton Hall. George Shadbolt, Vice-President, occupied the Chair.

The minutes of the last meeting were read and confirmed.

Mr. Barber exhibited some excellent photographs of scenes at Shanklin, Bonchurch, Ventnor, &c., in the Isle of Wight, the negatives having been taken by the oxymel process.

Mr. Fox, of Little Britain, was elected a member of the Society.

Mr. Hill read a paper upon *A Modification of Mr. Maxwell Lyte's Meta-gelatine Process*, an abstract of which will be found at page 110.

A vote of thanks was awarded to Mr. Hill.

Mr. Barber suggested the use of oxalic acid instead of sulphuric acid for making the gelatine, on the ground that oxalate of lime is absolutely insoluble.

Mr. Hill stated that he dried the plates before the kitchen fire (of course with the room darkened) without any detriment to the sensitiveness of the plate, not only drying them after they have become surface-dry, but also as soon as all flowing moisture had ceased.

The Vice-President drew attention to the use of hot bricks for the purpose, as had been recommended by Mr. Keene for Fothergill's plates.

Mr. Barnett exhibited a plate showing the effect of unequal drying by heat in producing stains, and considered that as a drawback to artificial drying.

Dr. Riley exhibited some negatives by his modification of the collodio-albumen process, as published in a former number of this Journal.

Dr. Riley considered that Fothergill's process is not so certain or simple as that he employs. He stated that he believed the true theory of the sensitiveness of his plates consisted in the altered structural condition of the collodion film by coagulation, and not from any compound being formed with silver. He asserted that a collodion film being sensitised and *thoroughly* washed from free nitrate of silver, coated with albumen, and again washed thoroughly while wet, and subsequently immersed in boiling water to coagulate the albumen—it dries in about a minute after removal from the water—and if then exposed in the camera, it is highly sensitive to the action of the light.

The Chairman suggested the possibility (if Dr. Riley's theory were sound) of coagulating the albumen by means of a sulphate of iron bath, and suggested that some of the members should try this plan before the next meeting, as well as Dr. Riley's of coagulation by hot water.

It was proposed by Mr. Hannaford, and agreed to, that this discussion be continued at the next meeting, and that dry processes generally be taken into consideration.

Mr. Hannaford mentioned that he had obtained instantaneous pictures upon dry plates, and also others with an exposure of a few seconds of time, but that he was not in a sufficiently forward condition with his experiments to communicate his results. He mentioned, however the following facts:—After taking the plates from the sensitising bath, and slightly washing them, they are dipped into a bath of solution of citrate or acetate of soda (other allied salts will of course suggest themselves), by which proceeding all the free nitrate becomes converted into citrate acetate, or other cognate salt of silver. It now becomes advisable to pour over it some preservative solution (say albumen by Fothergill's method), but pictures have been taken by him without any preservative solution on dry plates. On a plate six hours after preparation he had taken an instantaneous stereoscopic negative.

The Chairman, in reply to a statement of Dr. Riley's as to his belief that no dependence could be placed upon plates prepared by Fothergill's method, remarked that he had been quite successful with plates $9\frac{1}{2} + 7\frac{1}{2}$ inches, with several kinds of collodion.

Mr. Dawson, Mr. Hill, Mr. Morley, Mr. Hislop, Mr. Dalton, Mr. Barber, and others, took part in the discussion.

The subject of Mr. Young's (Manchester) discovery of the possibility of fixing plates before developement was then alluded to, and the Vice-President mentioned that he had within the last few days tested the point, and found a camera exposed plate developed perfectly after removal of the iodide by hyposulphite of soda.

Mr. HUGHES mentioned some interesting facts, ascertained by his experience, relative to the comparative rapidity of impressionability of plates when developed by iron solutions or by pyrogallic acid, as also the effect of bromides and chlorides in the sensitising solutions. He stated that with good collodion freshly *iodised*, and bath in good condition, and good light, the exposure required with either developer he found *the same*. If, however, the temperature were low, the light poor, the collodion old, or the bath acid, the *iron solutions* had decidedly the advantage. The addition of *bromides* he found to require an *increased* exposure (to nearly thrice as long) when pyrogallic acid developers were employed, but not any longer with iron. Chlorides required a little more time with the iron, but with pyrogallic greatly retarded the effect.

Votes of thanks were accorded to Dr. Riley and Mr. Hughes for their respective communications, and the meeting separated.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

THE Annual Meeting of this Society was held on the 13th ultimo. Mr. HOOPER, in the absence of both the President and Vice-President, was called to the Chair.

The SECRETARY read the minutes of the last meeting, which were confirmed.

Mr. JAMES HODGSON was appointed Auditor, to examine the Treasurer's accounts for the past year.

The Annual Report was then read.

REPORT.

The retiring Council, in conformity with the rule which requires them to lay before the Annual Meeting a summary of the proceedings of the Association, beg to lay their Report before the members.

Twelve meetings have been held during the past year, the proceedings at which are as follows:—

April 14—Election of Officers; Annual Report read; Discussion on the cause of the separation of the Collodion Film from the Glass in the Aceto-nitrate Bath.

May 12—Mr. WARDLEY: Paper "*On Waxed Paper Process.*"

June 9—Mr. HEYWOOD: Paper "*On Taupenot's Process.*"

July 14—Discussion on Mr. Wardley's Paper.

August 14—Discussion on the proper Exposure to Light of Sensitive Surfaces under peculiar circumstances; Mr. LEECH and Mr. DEANE: Communications on Levelling Stands.

Sept. 8—Mr. HEYWOOD: Paper "*On Fothergill's Process*;" Mr. DEANE: Communication on the Preparation of a highly Albumenised Paper.

Oct. 13—Discussion on Mr. Heywood's Paper.

Nov. 10—Discussion, introduced by Mr. Hooper, on Photoglyphs and several other subjects.

Dec. 9—Dr. ROSCOE, the President: Paper "*On the Measurement of the Chemical Action of Light*;" Mr. HOOPER: Communication on Carbon Printing; Mr. HEYWOOD: Communication on Alkaline Chloride of Gold Toning.

Jan. 12—Discussion on Printing and Alkaline Gold Toning; a circular Moveable Diaphragm was exhibited by Mr. HOPE; Discussion on Washing Prints, Dark Slides for Dry Plates from milled-boards, and Developement of Pictures in Daylight.

Feb. 9—Mr. HOOPER communicated a Self-acting Method of Washing Prints.

March 9—Mr. ROGERSON: Paper "*On Enlarging Photographic Pictures*;" and Nomination of Officers for the ensuing year.

The Treasurer's accounts are on the table, and have been found correct by Mr. Hodgson, who has been appointed auditor. They show that the Society has funds to meet all its engagements, and a balance of £1 15s. 3d.

Your council regrets being compelled to announce a falling off in the numbers of the members of the Association, but sees no reason to doubt the ultimate usefulness of the Society. Any person who has had much to do with public societies understands the case. The ardent photographer gathers around him many kindred spirits, and success crowns their united efforts; but many who have joined from curiosity fall away in the first or second year, leaving only those who can assist each other; and the Council believes that the Society consists now of more practical working photographers than it ever has done before.

If members wish the Society to progress, they must second the efforts of the Council by canvassing for new members amongst *photographers*.

The attendance at the meetings in July and August being small, owing to several causes, the Council suggests that Rule 9 be altered to discontinue the meetings in those months. The punctuality of opening and closing the meetings has been discussed in the Council, and it recommends that the business commence at eight o'clock precisely, and close at half-past nine. The irregularity into which the Society has fallen in this respect of late is a serious inconvenience to those members residing at a distance.

The Council believes that increased interest would be given to the meetings by a short summary of the most interesting news relating to photography; it would furnish abundant material for discussion and experiment; and it is happy in being able to announce that a member, whose services to photography are well appreciated, not only in, but beyond the circle of this Society, will perform that duty.

It was moved and seconded that the Report now read be received, approved, and adopted, which was carried unanimously.

It was moved and seconded that the best thanks of this meeting be given to the President, Vice-President, Treasurer, Secretary, and Council for their services during the past year, which was carried unanimously.

The votes for Officers were taken by ballot. Two gentlemen were appointed scrutineers, who found—

Professor Roscoe was elected *President:* Mr. Nicholson, *Vice-President*; Mr. Heywood, *Secretary;* Mr. Hooper, *Treasurer;* and Messrs. Meredith, Rogerson, Wardley, Whaite, Thelwall, and Fawcett, *Council.*

Mr. HOOPER then read a summary of intelligence from the photographic publications.

Mr. WARDLEY exhibited a box for storing sensitive papers, which he believed was as good as any now in the market; any tinman could make one. The only point to be guarded against was admission of the atmosphere; and a perforated box, containing chloride of calcium to absorb any moisture therein, should be placed inside with the papers.

In reply to an inquiry as to the cause of the creasing and running up of the albumen on collodion after fixing in hypo', Mr. WARDLEY stated that some samples of hypo' act so, but that he found it corrected by adding a few drops of acetic acid to the fixing bath.

Nine gentlemen were elected as members.

It was moved and seconded that the words "except the months July and August" be added to Rule 9.

The thanks of the meeting were then given to the Chairman, which concluded the business.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on Tuesday evening last, the 26th ultimo. Mr. HOWELL, one of the Vice-presidents, occupied the chair.

There being no paper to be read, various matters connected with photography were discussed. First came the point started by Mr. Johnstone at the previous meeting, as to the best mode of preparing French paper, so as to free it from the inferior sizing to which it was subjected. The process was again described in terms similar to those already reported in this Journal.

Mr. OSBORN mentioned that, some time ago, when working the calotype process in Suffolk, he met with a continuous succession of failures; up to a certain point the negative came up well, but then it gradually went brown all over.

Mr. JOHNSTONE said this might arise from more than one cause. If there was a small excess of nitrate of silver in the iodised paper, or an excess of iodide of potassium left in it, it would brown; and this would also be the result if it were under-exposed, and a developer with an under proportion of acid were used.

Mr. OSBORN: These were tried in every possible way—long exposure and short exposure; but all browned in the developing.

Mr. JOHNSTONE: After you have washed the paper by the double wash, if it gets the slightest gleam of light it will be good for nothing: you would not discover it till after you have developed.

Mr. OSBORN: Do you mean to say that iodised paper always ought to be kept in the dark?

Mr. JOHNSTONE: Yes, while it is being prepared. You should not prepare a paper by strong candle light unless there is a yellow shade.

Mr. OSBORN: Many people, in using single wash, coat the paper in an ordinary lighted room.

Mr. JOHNSTONE: In single wash you do not run any risk, because the nitrate is entirely neutralised by the excess of iodide.

Some conversation next took place regarding the various photographic agents, Mr. JOHNSTONE stating that fourteen years ago he used iron for this purpose. His first experiment was with some sulphate of iron which had been made eighteen months. He took

a piece of paper, washed it with nitrate of silver, dried it, put a small lithograph in contact with it, put glass over it, and held it in the sun till he had counted a hundred. He then took a little of the sulphate of iron, poured it into a flat dish, immersed the paper, and in five or six seconds a tolerably fair negative was developed. The next experiment, being with a new solution, did not answer. The sulphate first used had no doubt become peroxydised to a considerable extent, so that there was acid which kept the pictures clean.

The subject of Nièpce's "bottled up light" was next introduced by Mr. JOHNSTONE, who asked whether any gentleman had made experiments?

Mr. BOURNE said he had done so, but had signally failed.

Mr. JOHNSTONE said he had tried similar experiments as M. Nièpce, but had come to different conclusions. What M. Nièpce said was in reality no conclusion. He said the light was absorbed and was given out after a time, but, unfortunately for the notion, the same results could be produced in two different ways without the action of light at all. Both electricity and heat could produce them.

Mr. OSBORN said one singular thing was that this "bottled light" would not pass through glass. If it was really a bottled light one would think it would pass as well through a glass negative as through paper, just as with heat.

Mr. JOHNSTONE said Daguerre asserted that electricity was the great exciting cause in photography, but he never showed the mode of action. He (Mr. J.) hoped, in a short time, to be able to explain how chemical action arose and was carried on.

After conversing about the best form of tent, &c., the meeting adjourned.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

INTRODUCTION.

COLORED photographs occupy an undeservedly questionable situation: the artist curls his lip at them, and the photographer regards them with a sneer. The one says they are no paintings, the other that they are no photographs; thus the art of photographic coloring, unrecognised by either, must seek consolation in the fact that it is embraced none the less eagerly by both. At exhibitions of paintings colored photographs are peremptorily refused, and it is very frequently advised that they should not be received for photographic exhibitions. The truth is that an artistically painted photograph combines the best and highest qualities of both photography and art:—the camera providing truthfulness of light, shade, and resemblance; the painter adding those beauties and effects from which all pictures derive their greatest value. A mere likeness is valuable during the life of its possessor, but cannot outlive the love or respect of the friend or relative who may chance to own it; while a genuine work of art "will preserve the remembrance of the homeliest woman and the poorest individual, when every trace of the most beautiful female or the most august sovereign have been swept by time from the memory of man." If the beautiful and the true are united, their productions surely claim the very highest standard of worth, surpassing all those which are merely true or merely beautiful.

Let the scientific man of the camera and the studious son of the pallette, then, throw aside all their childish jealousies, and combine their efforts for the production of works valuable both for fidelity to nature and artistic merit.

"Unity is strength," and the truthful can have no better mate than the beautiful.

The best interests of photography are served by advocating its union with art, in demanding for it a much higher standard of worth than it can ever claim as a simple mechanical acquirement, calling for no greater intellectual effort than that implied by carefulness and manipulatory skill.

Photography should stand as high in the domain of art as it does in that of science, and its professors should consider the principles and theories of great painters as legitimate a branch of their study as optics and chemistry.

The photographer who has mastered the philosophical principles of his art knows the difficulties he meets with in combatting its imperfections. The effect of form is dependent upon light and shade, but, independent of this, colors having in themselves photogenic power produce in the photograph both lights and shadows, thus effecting a positive alteration of more or less consequence in form itself.

Of no less importance are objections arising from the imperfect nature of our optical arrangements, such as the distortion of advancing and receding objects, without referring to others demanding a more complicated and detailed description.

This being the case the advantages of an educated eye must be apparent to every photographer, as he may otherwise overlook upon the focussing glass of his camera remediable errors, and perpetuate them in his photograph to the injury both of himself and his art.

In the next chapter, I shall venture to suggest some of the more prominent principles of pictorial effect in connection with photographic portraiture, and in conducting my instructions to a close, I shall always so endeavour to combine the practical and theoretical, that the *how* may be safely founded upon the *why*, hoping to beget that habit of thoughtfulness in the student without which there is little chance of ultimate success.

Permit me to remark, that no department of the fine arts possesses greater claims to feminine attention than photographic coloring, the demand for its professors is fast increasing, and colored photographic portraiture bids fair to outstrip all its rivals, many of my pupils have been ladies, some of whom are now well known as accomplished and meritorious colorists.

If in the course of these chapters any of my readers should find passages at all imperfect or obscure (which as I have no pretensions as an author is probable), I shall very willingly answer any questions they may please to ask, or give any further information they may think necessary for successful progress.

(To be continued.)

Letters to a Young Photographer.

No. IX.

MY DEAR EUSEBIUS,

Do I remember your grandmother? That dear delightful old lady, to whom we paid a flying visit on our way to the Lakes? When I forget her, may my right hand forget its cunning. Is she not as fair and prim as a maiden of eighteen? is not her voice as melodious as the note of the blackbird? and is not her face radiant with smiles, such a one as only a Raphael could paint? Shall I forget her whipt syllabubs—her strawberries and cream, and those tea-cakes, which refreshed us, after our dusty journey, like manna in the wilderness, while seated in the jessamine arbour? No, never! Should I like to see a portrait of her? Aye, indeed; should I not? Would I not frame it, and place it in the post of honour in my studio, as a trophy of your skill in photography, and as the picture of a model woman. It is an honour to your head and heart to devote the first essay of your skill to the obtaining her fair counterfeit; and you cannot fail to triumph over all difficulties, if you but exercise your skill with due patience and deliberation.

How shall you take her? I would have her seated in the jessamine arbour, with that quaint old-fashioned tea-service before her, which she boasts was the property of *her* grandmother. I would place Fido at her feet, and the favourite cat on the opposite seat—there will be a picture, which will gain you a prize and "honourable mention" at the next Exhibition. I think, if you plant your camera under the great walnut tree, you will find the jessamine arbour and its contents to come nicely into a $8\frac{1}{2} + 6\frac{1}{2}$ plate. Be very particular in focussing. When the image appears on the ground-glass, if it be indistinct, you must move the screen first backwards, and if the indistinctness increases, then bring the screen nearer to the lens, until you are satisfied with the sharpness and brilliancy of the picture. Many operators think it necessary to employ a "focussing glass," and I dare say they find their account in it; for my own part, I can do without one.

Now comes the crisis! You are about to take a picture! and you feel—don't you—as you did when you first pulled the trigger of that confounded old blunderbuss, that kicked and knocked you over last Guy Fawkes' day. Never fear, your camera won't kick, although it may capsize some windy day, and cause you to find your level prone on mother earth.

Now, I suppose you have a collodioned plate all ready in the dark slide. You place the cap on the lens, withdraw the focussing screen, and put the collodion slide in its place, having coaxed dear old granny to "sit quite still for just half a second." She does her best, but not being used to pose to artists she soon forgets the injunction, and just as you place your finger on the trigger (I mean the cap) she enters into confidential intercourse with Tabby, nodding her head and smiling all over her face. You pause, this will never do! You do not wish her to look like a Chinese mandarin, and so wait

till the sentimental fit is over, and mildly repeat your warning gently insinuating that "the operation is going on;" to which she promptly replies—"Yes, I know. I feel it going all over me like a cold chill!" You argue—it is nothing, it will soon be over, and with this assurance a mesmeric influence is established, and you get sufficient time to remove the cap, and, lo! the picture is taken.

Of course the dear old lady wants to see how she looks, and coaxes you to open the slide, as she has to go to see about dinner and cannot wait. You expostulate, and urge that nothing can be seen of the picture until after it is "developed." She urges: "she is not particular, she had rather not, it will do as it is," but your remonstrances prevail, and you make good your retreat to your dark room.

I cannot give you any precise instructions as to the time of exposure which will secure a good picture; there are many things to be taken into consideration which I will briefly enumerate. First, there is the power of the lens, dependent on its length of focus, and on the principles upon which the "objectif" is constructed; secondly, there is the degree of illumination of the object, and its tone of colour; and lastly, there is the sensitiveness of the collodion, to be taken into account. Now, it is impossible you can work by fixed rules amid these variable controlling influences. An inch or two of difference in the focus of a lens will effect a second or two difference in the time of exposure, other things remaining the same. As a general rule, the shorter the focus the quicker the picture is taken. As the collodion is affected in proportion to the amount of light reflected from a given object this latter must, of course, always form a variable quantity in operating with the same lens; and this again is governed by the quality of the collodion employed, some being much more sensitive than others. Therefore, if two of your elements of operating are constant, you may, by one experiment, arrive quickly at a knowledge of the unknown quantity of the third. For example, you first wish to ascertain if you are working with a quick lens or a slow. To establish this rigorously you experiment with the same collodion, upon the same object, the camera at the same distance from it, and at the same hour of the day, when the amount of illumination is identically, or nearly, the same. If you move your camera, or change your collodion, or repeat your experiment in the afternoon instead of the morning, you will not be able to tell which influences the result, whether it be distance, light, or collodion; and in this state of confusion, your lens, which you think are testing, is—nowhere.

Suppose you wish to test a sample of collodion, you must change only this one element of the operation; the camera, the distance, and the amount of light must be fixed elements. You will know by the result whether your picture has been over-exposed or under; if the latter there is no remedy for it, but do not give way to the weakness so many photographers indulge in—that of seeking to obtain pictures in less than no time. In the majority of such abortions all the qualities that constitute a really good picture are absent. There are no half-tones; the shadows are dry and opaque instead of being clear and transparent; the lights look abrupt and glaring, as if they had run away from the shadows; there is, in fact, a total absence of what painters call breadth, and a want of harmony of tone, which places such productions out of the pale of art altogether. Yet you will see such things held up for admiration, on the sole plea of having been taken in nineteen-twentieths of a second. Much better is it to take fifteen or twenty seconds, if they be required to obtain a good picture. Why, when I first began to take Daguerreotype portraits, my sitters thought themselves lucky if they could get off with a five minutes' pose; a pretty severe trial this for fixed attention. As soon as the cap was removed, I used to sit down and read a chapter in the last new novel while the operation was going on, and generally managed to get through it before I considered my picture *done;* but, as the French say, *nous avons changé tout cela.*

Photographic Glossary.

Iodates—Salts formed by the union of iodic acid with bases. They generally resemble the chlorates.

Iodate of Potassa—A salt obtained by the action of iodine on solution of potass. It crystalises in small cubes, and is permanent in the atmosphere. In alcohol, sp. gr. 810, it is insoluble, and requires fourteen times its weight of water at sixty degrees to dissolve it. In iodide of potassium it is more soluble. Iodate of potassa is decomposed by heat into iodide of potassium and oxygen gas.

Iodate of Silver—When to a solution of nitrate of silver iodate of potassa is added, iodate of silver is precipitated in the form of a white powder which is very soluble in *liquor ammonia.* From this solution it is deposited in small rectangular prisms which are free from ammonia.

Iodic Acid—A compound of one equivalent of iodine and five equivalents of oxygen. It may be prepared by the direct oxidation of iodine by nitric acid, or by the action of sulphuric acid upon iodate of soda. It is a very soluble substance; it is decomposed by heat, and its solution is readily deoxidised by sulphuric acid. It crystallises in six-sided tables, which contain water.

Iodides—Compounds of iodine with metallic and other bases. The principal iodides employed in photography are those of ammonium, cadmium, potassium, zinc, and silver.

Iodide of Ammonium—A deliquescent salt composed of iodine and ammonium. It is obtained in colourless cubes, which are anhydrous, but extremely soluble both in water and in alcohol. It is used as an iodiser for positive collodion, but it is not suited for negative on account of its great instability. It is also called hydriodate of ammonia.

Iodide of Cadmium—A compound of iodine with the metal cadmium. It is permanent in the atmosphere, and very soluble in alcohol and water. It is much employed in iodising collodion, which does not become discoloured by the liberation of iodine, as when iodised with the salt of potassium. Iodide of cadmium is considered to impair the fluidity of collodion.

Iodide of Potassium—A white salt composed of iodine and potassium. It is anhydrous; slightly deliquescent, and very soluble in water. In absolute alcohol it is scarcely at all soluble: in dilute alcohol it is soluble in proportion to the quantity of water present. This salt is extensively used in photography, both in the collodion and in the waxed-paper processes.

Iodide of Silver—This salt is formed when a soluble iodide is added to a solution of nitrate of silver. It is of a primrose yellow colour, insoluble in water and alcohol, and slightly soluble in nitrate of silver. It dissolves in iodide of potassium, forming a double salt. It is nearly insoluble in ammonia. It is very sensitive to the action of light, and is the principal agent in obtaining photographic pictures.

Iodide of Zinc—Iodine and zinc combine with great energy, producing a brownish deliquescent white salt in prismatic crystals. Its aqueous solution decomposes very quickly when exposed to the air. This salt is sometimes employed in photography, but its instability does not recommend it.

Iodine—An elementary body, of great importance in photography, obtained from certain seaweeds. It was discovered in 1814. It is solid, existing in the form of blueish-grey scales, which are readily volatilised by heat in the form of a beautiful violet vapour. It possesses an odour similar to that of chlorine. It is nearly insoluble in water, but soluble in alcohol and ether, which it tints yellow or reddish-brown; it is also soluble in chloroform and in sulphide of carbon, which it colours violet. It stains the skin and most animal and vegetable bodies yellow, but the colour quickly disappears, unless the organic substance has become decomposed. Iodine is extensively employed in the daguerreotype process and in the preparation of the various iodides.

Iron—Some of the salts of this metal are employed in photography, as the citrate, sulphates, hydriodate, iodide, &c. The protosulphate of iron is the most energetic developing agent employed.

Isinglass—The purest form of gelatine, consisting of the air-bladders of sturgeons. It is white, semi-transparent, devoid of smell and taste, softens in cold water, and dissolves in boiling water. It is recommended for use in photography by those who consider it superior to artificially prepared gelatine.

Ivory, Artificial—A substance so-called has been employed in photography for receiving photographic images. It is prepared by mixing sulphate of baryta with albumen, and rolling the plastic compound into sheets. Another kind, known as Pinson's, is obtained by immersing sheets of gelatine in acetate of alumina; when dry it will receive a fine polish.

Kaolin — China clay, pipe clay. A very white and pure clay, used in the manufacture of porcelain. It is composed of silica and alumina. It is much employed in photography for removing the colour of nitrate of silver baths, produced by the action of organic bodies, such as albumen, gelatine, &c. Paper is prepared in Germany with a surface of kaolin, like that of "enamelled cards," upon which proofs may be printed with very delicate and fine effect.

Foreign Correspondence.

Paris, April 23, 1859.

THE researches of M. Nièpce de Saint Victor in the matter of "bottled light" have not met with that candid reception and philosophical treatment we were justified in expecting from the country that has produced a Bacon, and which professes to conduct all its philosophical investigations on the inductine system laid down by that profound philosopher. It is but too evident that photography and philosophy rarely shake hands. They might be friends, perhaps, were it not for the jealous interference of empiricism.

M. Nièpce has just cause to complain of the manner in which the accuracy of his discoveries has been questioned; still more at the summary fashion in which they have been repudiated upon an empirical test. It was hardly worth his while, still he thought it necessary, to condescend to reiterate his assertions, and to point out to those who have professed to test his conclusions, the blind errors of their proceedings. The unlearned run little risk in implicitly adopting any conclusions upon which so profound and sagacious a philosopher as M. Chevreul has placed the seal of his approval. At a recent meeting of the *Académie des Sciences* that *savant* read, with approval, a note from M. Nièpce to the following effect:—

"By a simple experiment I can reply to the objections which have been made to my discoveries of the persistent activity of light. I placed in a refrigerator a tin tube, containing some cardboard, impregnated with tartaric acid. Exposed a sufficient length of time to the action of light, this tube was left surrounded with ice for the space of eight and forty hours, covering its orifice with a piece of paper rendered sensitive with nitrate of silver only, and dried. A piece of thin printing-paper, impressed with large letters, to serve as a negative, was interposed between the orifice and the sensitive paper. At the expiration of forty-eight hours I concluded that the 'bottled light' had acted sufficiently: I treated the sensitised paper with gallic acid, and the result I now present to the inspection of the meeting. Had the sensitive paper been prepared with *iodide* of silver instead of the *nitrate*, the image would have been much more vigorous; but such as it is, it proves, beyond doubt, that an action is really exercised by light, independently of *calorific* radiation; and that is all I wish to prove at present.

"As to the action of heat, I am aware it exists, since it has manifested itself in many experiments performed months ago, the results of which I shall soon make known; but to establish my priority of claim, I will at once state, that employing the obscure radiations emanating from a source of heat of 212° F., I obtained at will positive and negative pictures, according to the preparation of the paper. It is then evident that, under certain circumstances, heat may produce the same results which, in my first researches I attributed to light. Calorific or luminous radiations undoubtedly exercise chemical actions, which are quite distinct from each other, and which must not be confounded, even when they are exercised simultaneously. At a time when the distinction between the luminous and calorific effects was not so clear in my mind as now, I recommended that the tube containing the 'bottled light' should be warmed, I obtained a more rapid and and more intense impression, because the two effects were combined; but the experiment recorded above, in which the calorific agency is nullified, proves that light alone, independently of elevation of temperature and of moisture, is sufficient to produce very vigorous proofs.

"As to the objections derived from the fact that the image is not produced when a thin plate of glass or of mica intervenes, it is only necessary for me to refer to my first memoir, presented to the *Académie* on the 16th of November, 1857. I then remarked that the activity communicated by the 'bottled light' would not pass through glass; in this respect it resembles the luminous radiations emitted by burning phosphorus, which have no influence upon sensitised paper."

Very great interest was excited at the meeting of the *Académie* by the exhibition of some magnificent coloured photographs, executed by M. Victor Plumier, according to certain variations in M. Nièpce de Saint Victor's nitrate of uranium process. The colours in which they are printed are light and deep tones of green, lustre, orange-red, and sky-blue, of a purity and brilliancy truly surprising. These charming proofs exhibit one of the most beautiful applications of chemistry imaginable, which opens an unlimited extension to the boundaries of photography. M. Chevreul expressed the great pleasure and pride he felt in the labours of his indefatigable *protégé*. I will give the process by which these remarkable productions are obtained.

For red proofs — prepare positive paper with a solution of nitrate of uranium, of the strength of 20 per cent., leave the paper fifteen or twenty seconds in this solution, and drain and quickly dry it in the dark. Paper so prepared will keep good several days. The exposure in the pressure-frame will vary according to the intensity of the light and the strength of the negative: from eight to ten minutes in sunshine, and from one to two hours in cloudy weather.

On removing the proof from the printing-frame, wash it for a few seconds in water of a temperature of 120° to 140° F., then immerse it in a solution of red prussiate of potash of the strength of 2 per cent. In a few minutes the proof will acquire a blood-red colour; wash it in several waters, until the last remains limpid, then leave it to dry.

To obtain a green proof, take a red one, prepared as described, and immerse it for a minute or so in a solution of nitrate of cobalt, withdraw it, and without washing, dry at the fire: it is fixed by being placed for a few seconds in a solution of sulphate of iron, of the strength of 4 per cent., and 4 per cent. of sulphuric acid; wash in one water, and dry at the fire.

Violet-coloured proofs are obtained upon paper prepared with nitrate of uranium, as indicated for the red proofs. On removal from the pressure frame, wash the proof in warm water, and develope it in a solution of chloride of gold, of the strength of two grains to the ounce of water: when the proof has assumed an agreeable violet colour, wash it in several waters, and dry it.

Blue proofs are obtained by preparing negative paper with a solution of red prussiate of potash, of the strength of 20 per cent., and drying in the dark. Paper so prepared will keep several days. On removing the proof from the pressure-frame the solarised parts will have acquired a light-blue tint, it is then placed for five or ten seconds in a cold-saturated solution of bichloride of mercury; afterwards rinsed in one water; then immerse it in a cold-saturated solution of oxalic acid, warmed to 120° to 140° F., wash it in two or three waters, then dry.

It will be understood that this result, beautiful as it is, in no way solves the great problem of printing in natural colours. To obtain this coveted boon, we must first discover a chemical substance capable of assuming all the myriad-tinted hues of nature. Do we know of any such chemical chameleon? Shall we ever discover it? Perhaps so: in the same year with the Elixir of Life and the Philosopher's Stone! J. P.

New York, March 30, 1859.

THERE is so very little stirring at present among us in photography that material for a letter is not easily accessible, as nothing comes to the surface worth transcribing. The Journal mentioned in my last, popularly known as *Anthony's Monthly Advertiser*, for the 1st January, 1859, is yet unpublished (March 30th), and the *on dit* is that it is defunct for the lack of bank paper. *Humphrey's Journal* has changed hands; whether its "policy" will be changed or not remains to be seen, but it is to be hoped, at any rate, that something may yet appear in it worthy of the bright actinic atmosphere of America. Its new proprietor has extensively advertised his wishes to get matter for its pages from professional men; but I fear he has had the trouble and expense for his pains, unless he follows in the footsteps of his predecessor. Hitherto the American Journals have contented themselves with reprinting the articles, without selection, as they have appeared in your and other Journals of Europe, even your translations, typographic errors and all, and crediting the original Journal for the article itself and themselves as the translators, although neither of them can read any other language than the "American," and not that correctly.

I have just seen several cameras of the largest dimensions tried; their success was really astonishing, the image being impressed more rapidly than I should have imagined such large instruments to have done, and with a degree of sharpness and clearness not to be surpassed in a small instrument.*

* Our American cousins often attribute to the *camera* what we do to the *lens*, and thus give great credit for speed to the *carriage* instead of the *horse*.—ED.

These large cameras seem to be the order of the day here at present as well as in South America, whither some of those I saw were bound. All of them are portrait cameras, and are unquestionably the best made in America, as your readers may readily understand from the fact that for so many years they have held their own in the market, without having any Journal to celebrate their good qualities, as is the case with their only rival, which are as celebrated as the utmost efforts of *two* Journals could effect, whose whole energy seems to have been devoted to this exclusive purpose.

Notwithstanding this lack of *celebration*, the cameras of Holmes, Booth, and Hayden are as widely known as any instruments of American manufacture. The lenses are all made of imported German glass, and entirely worked by able German artisans.

Some of our public practitioners who have made cheap or rather *low-priced* "face-maps," advertise to sell out their stock and good-will, as they have made as much money as they desire out of a business which they say has averaged 50,000 dollars per year! All have not been so lucky.

Nothing new in the way of apparatus has recently come under my notice, although I visited all the respectable ware-rooms for the purpose of seeing any such, if on sale.

The oldest establishment of the kind in this city is that of the *Scovill Manufacturing Company*, which is the most extensive in America, and has been in the business from its earliest days. Here everything required in the art may be obtained, and I am not certain that any house in London or Paris is more complete in its arrangements than this. This firm sends a large quantity of goods to Europe, and its annual receipts must be immense to keep so many employed in the sales' department alone.

Second to this house in the *age* of their establishment is *Holmes, Booth, and Hayden*, already mentioned. Their establishment is hardly so extensive as that of the former, but for the quality of their goods they are not be surpassed; while with their cameras they cannot be approached, so far as I have had an opportunity of judging.

In my next I may have a few words to say of some of the other houses in the business, and as both time and space are alike exhausted for the present, I must make my *congé*.

ARGUS.

Correspondence.

DETAILS OF HONEY PROCESS.

To the Editor.

Sir,—Having generally been as successful as perhaps most amateurs with Taupenot's and Fothergill's dry collodion processes, but wanting to expose three or four plates near home, on Good Friday, it occurred to me that the honey process would be the most easy to manipulate.

I accordingly set about to prepare the plates; and, first of all, after cleaning, took the precaution to albumenise them, as recommended by Mr. M'Nab (although I believe Mr. Barnes was first to make known this plan); with the collodion I used it was, perhaps, needless to perform this operation; but having seen the collodion film slip off the glass, there was no harm in trying the experiment. I need scarcely add, that in this particular I was successful, for no amount of rough washing affected it in the slightest degree.

The collodion was Keene's, iodised last September, and now is scarcely tinged with yellow. The bath was prepared, according to Mr. Thomas's directions in the *Journal of the Photographic Society* for August last. The plate coated and sensitised in the usual way, drained, and a portion of honey solution poured on and off two or three times (the honey having been prepared twelve months), and drained for about half-an-hour.

Before going out, I exposed a plate, as an experiment, on a view from the window—Petzval lens, eleven and a-half inches focus, half-an-inch stop, three minutes. On developing it (iron one drachm, citric acid four grains), the picture started out immediately, and was very red and feeble by transmitted light. I concluded it was over-exposed.

I went out, and gave the first plate one minute, the next two minutes' diffused light; on applying the same developer to the plate exposed one minute, the picture started out almost as soon as before. The detail was all there, but very feeble, no after treatment bringing up the intensity. I developed the two-minute plate with pyrogallic acid: the image appeared at once, but was, if anything, rather more intense, although useless for printing. From this one might infer that with a honeyed plate, a short time after preparation, instantaneous pictures might be taken with suitable lens, &c.

Would you recommend more acid in the bath, or a more highly coloured collodion (both are in good order for the wet process), or to work on with the same, giving shorter exposure, or a weaker developer? The *modus operandi* is so simple, I would like to be able to work the process occasionally. There is, though, a great difficulty in clearing the iodide off the plate. I steeped it in hypo two hours, and then by reflected light, the image appears quite grey and misty, just as if it had not been fixed.

Yours, &c.

CAUSTIC.

[Our correspondent has hit upon a direction in which we have been making some experiments—and which we have been obliged from circumstances to set aside for the moment. We are not so sure even now that his misty picture is not available, that is, if he has left it intact.

We found that proceeding just as above described, we got an impression with a very short exposure, but, what is very singular, the picture *was not in the collodion* but in the albumen, for we removed the whole of the collodion, by washing it with water and rubbing it with a sponge, and with the collodion we *took off all the fogginess.* Unfortunately we handled it very roughly, and scratched the albumen with some particles of grit in the sponge; but we have no doubt that, with very little care, the collodion might be entirely removed with a wet tuft of clean cotton, and the negative subsequently intensified with pyrogallic acid and silver solution. We think there is an excellent field open here for experiment. With regard to the honey process itself, we find it of the utmost convenience where we wish to prepare and use plates at a short notice, which we sometimes have done before breakfast of a morning, including exposure, leaving the developement till night or the next day. We find that one part of syrup to three of distilled water is quite strong enough for the purpose, and is much more pleasant to manipulate with. The previous coating of the plate with albumen should be avoided, and is quite unnecessary, especially with Keene's collodion, which by the way we find admirably adapted to this process.

Before concluding we would remark that we have recently met with honey which produces a milkiness of appearance on being first poured over the plate—we have found a remedy in adding about ten drops of 30 grains of solution of nitrate of silver to each ounce of syrup *in the dark*, allowing a precipitate to fall and filtering the syrup—no darkening takes place, nor does the syrup turn milky when used subsequently. [Ed.]

IRON DEVELOPER WITH SYRUP, &c.

To the Editor.

Sir,—In the April 1st number of your Journal, page 78, you recommend honey syrup to be added to the iron developer, for dry plates. Please kindly inform us (1) how to prepare the honey syrup, (2) and if it may be used also for wet plates, with the iron and citric acids of same proportions, and oblige,

TWO CAPTAINS ROYAL ARTILLERY.

[1. Take of honey *two* parts by measure, distilled water *three* parts: place in any convenient vessel, and dissolve thoroughly by heat; filter through bibulous paper, an operation that proceeds very slowly.

The object of filtration is to remove the pollen, &c., which is always present in honey, and would cause spots if left in the syrup.

One use of this syrup with the iron developer is to produce *intensity*, which it does in a marked degree.

2. We do not recommend citric acid with the iron developer for *wet* collodion, because it does not mix readily with the solution of nitrate of silver on the plate, acetic acid in this case answering better; but the syrup is just as useful as with dry plates, and acts in a similar manner. —Ed.]

FLASK APERTURE.

To the Editor.

Sir,—I am afraid I cannot shelter myself under your editorial ægis in relation to my bottle diaphragm, or rather *aperture*, as I was fully aware of the construction of *Marten's* panoramic camera,—having not only seen several, but made one with my own hands. But in reply to your correspondent, W. E. Kilburn, p. 63, I may say I did not claim to have invented it, for I said (p. 5), "send you the description of the diaphragm and aperture I have now *used* for several years." I leave all the *re*-inventions to his own countrymen, some of whom are exceedingly expert at this process, there being here now two recently patented diaphragms, both of which were described years ago in various Journals, to say nothing of that "bromide in collodion." I would further say, that I go further back in my reading than Mr. Kilburn himself, for the idea of stopping out a portion of the rays from any part of an object which would act too powerfully on the plate belongs to *Lerebour*, of Paris, in the first edition of whose pamphlet on photography, on *research*, Mr. K. may find that L. used a leaf of a tree for effecting this object. From this I got *my* idea of the aperture, the chink *(fente étroite verticale)*, of the panoramic camera, such as in the sketch. This chink is rather narrower at bottom than at top, is placed immediately in front of the *plate*, and not near the lens at all, for its use is to circumscribe, not the rays admitted by the lens, but the part of the plate to be impressed, so that it is as long as the width of the plate, whatever that may be—even if as long as five or more times the entire diameter of the lens.

To avoid any further charge of *piracy*, I may say, that my scioptic camera *is* founded on Marten's panoramic camera, but only so far as the revolving box and the above chink are concerned, but no farther. *His* will only impress cylindrical plates, while mine impresses *plane* surfaces, such as albumenised or collodionised glasses. As every part of it, except the lens, was made by myself, the workmanship is not so perfect as if it were made by a machinist.

Mr. Kilburn will, I hope, see fit to institute what he recommends to others, "a little research," or else his candle *will* "go out in a stink" for neglecting to see whether an *invention* was claimed, instead of assuming such to be the case. I cannot profess to have read *all* that has been written on the subject, but I have read a tolerable proportion, and when I want to make claim to re-discover anything, I shall not, like a countryman of his, assert that although such a thing may have been printed by another before me, I have *ascertained* that no copy of *that* publication had reached this country at the time my discovery was printed here—even though a period of four months had elapsed, and ten days being ample for the purpose. *The Photographic Journal* reaches its subscribers in New York and Boston often in ten days, and seldom over fifteen from the day of its publication, although that fact is ignored by the circulars announcing a new process for sale, which has just been copied from its pages.—Yours, &c. WM. ROSS.

New York, March 28th, 1859.

COPYRIGHT.

To the Editor.

Sir,—Will you oblige me by an answer (in your notices to correspondents), to the following queries?

Suppose I purchase from the publisher of certain engravings the exclusive right of photographing for sale reduced copies of them, does the law protect me in such right? And does it protect me against photographic *copies of my photographs* from such engravings being issued for sale?—Yours, &c. L. M.

[This is a purely *legal* question, and as such we cannot be expected to give an authoritative reply; but so far as we understand what has been laid down as the law upon the subject, a copyright *does* exist as regards an engraving, and *any reproductions thereof of any sort*, consequently including photographs of it. Any one pirating a photograph of an engraving would therefore be amenable to the owner of the copyright or his assigns. It is held, however, that photographs of natural objects are not in the present state of the law protected by copyright.—Ed.]

PREPARING GLASS PLATES WITH ALBUMEN.

To the Editor.

Sir,—Referring to the last number of *The Photographic Journal* (April 15th), page 102, I perceive that your correspondent, Mr. Jones, of Cheltenham, has been a little perplexed with regard to the article upon coating glass plates with albumen. His difficulty, I think, arises from a slight error in the paragraph he alludes to, viz., the substitution of the definite article for the indefinite. Instead of reading "*the* plate was taken," &c., it would be better rendered thus:—"*a second* plate was taken," &c., &c. I would at the same time remind your correspondent that the method applies exclusively to the *preparation* of plates *previous* to their being collodionised, and is adapted for either process, wet or dry, negative or positive.

Plates prepared with albumen will not, however, work clean if kept for a length of time, hence the necessity of coagulating with iron; but if thus treated, and afterwards washed, dried, and stored away in a dry box, will work as clean as if newly prepared. In proof of this assertion, Mr. Young prepared four plates, and made trial of them at intervals, extending over a period of two months, and in *every* instance found them to give perfect results; this is one point satisfactorily established, viz., that plates thus coated will keep good for the above-mentioned time.

I wish it to be clearly understood that if the method be faithfully carried out, the result cannot fail to be successful; and here I would reiterate the assertion, lest any misapprehension may arise in any one desirous of following out the experiments, as it has been mentioned to me by a practical photographer, that it was a failure in *his* hands; upon inquiry, however, I found that the trial had not been fairly made, from the circumstance of his only adopting *one* part of the formula and rejecting the other.

I am further of opinion, that unless the albumenised plates be coagulated previously to being coated with collodion, there will be trouble with the silver bath. This opinion is confirmed from the fact, that those who have complained of their non-success have omitted this important point.

In reply to your other correspondent, "Querist," I would state that the advantages are: the adhesion of the films to the plates; saving trouble in cleaning the glass; also that cheap picture sheet can be used instead of patent plate: the exposure is the same, neither longer or shorter, and the developer, either protonitrate of iron or pyrogallic acid. Any *good* collodion, but I prefer my own make, the formula for which can be had at a future time, by those to whom it may be of service.—I am, Sir, yours truly,

Glasgow. A. M'NAB.

PHOTOGRAPHY FOR ORNAMENTATION.

To the Editor.

Sir,—I have often thought it strange that the same idea should suggest itself, and be carried out much in the same way, by more than one individual about the same time; the following is an instance:—

A few weeks since, I thought that portraits on leather, cloth, or paper, would be very suitable for putting upon books or book-markers, intended for presents to friends.

I procured a book and some markers, and attached leather portraits to them for show in a small case, when a young lady (a customer) told me that the last leather portrait I executed for her had been sewed on to a book-marker by a friend. Subsequently, other two persons told me they had seen photographs applied in a similar manner. I now find that book-markers, with photographs of engravings, pasted on one end, may be had at wholesale stationers at 4s. per dozen, which is cheap enough.

I was not aware that any other person had applied photography thus till after I had begun to do so.

I enclose a small leather portrait on a card.—Yours, &c.

Glasgow, April 19, 1859. A. R.

[Not only are photographs thus applied in London, but one firm, we believe, is pretty extensively engaged in preparing visiting cards with the owner's portrait attached. All that we have seen are, however, printed on paper.

The specimen sent by our correspondent has considerable merit—the whites are extremely good, and the lights generally not degraded in tone, as unfortunately generally is the case when transferred to leather.

If our correspondent is willing to communicate the details of his method of operation, we have no doubt it will be acceptable to many of our readers.—Ed.]

HINTS TO MANUFACTURERS.

To the Editor.

Sir,—I beg to suggest the desirability of making the groves of plate boxes in this fashion VVV, instead of the usual V shape; the backs of the plates would thus lie against the flat surface, whilst the faces would have the minimum of contact with the angular.

It would also be preferable to have them made of copper or tin (not tinned iron).—I am, yours, &c.

April 26, 1859. AJAX.

[We have seen racks made of the form suggested in *gutta percha*, by Messrs. Murray & Heath, of Piccadilly—a material, we think, better adapted for the purpose than copper. Tin (not being tinned iron) we do not consider at all available. We do not perceive any impediment to the use of wood for the purpose. Racks made of tinned iron are very useful for dry plates; and in this case, a form which we have in use answers beautifully. They are arranged as annexed—UUUUUUUUUU—Ed.]

ANSWERS TO CORRESPONDENTS.

A.—The cleaning of glasses, coating with collodion, &c., have been too often described to need further notice here.

Nathaniel V.—Perfectly correct—photosulphate of iron and *citric acid*.

F. C.—You do not mention what *sort* of lens, whether for portraits or landscapes, nor the size of the picture. We cannot, however, undertake to recommend any particular maker; but have no objection to state what principle of lens we should advise.

An Amateur—We have never tried to remove silver stains from marble; but should try the following, viz.—Apply, first, tincture of iodine to the spots pretty freely, and let it dry; then cyanide of potassium.

A Soldier—Many of the men amongst the sappers and miners are good photographers. We see no reason whatever to expect that your following the pursuit of photography could be offensive to your officers.

Printer on Albumenised Paper—We have recently tried a new make of English paper, which we much like—it was given us by Mr. Hardwich, and coated, if we mistake not, by Mr. Spencer; we will ascertain the maker's name for you.

Thomas Gulliver—Your specimen is not likely to have changed—it could not be worse: it is quite useless, and we will return it as you desire. We will endeavour, in a few days, to comply with your other request.

D.—We shall be most willing to help you out of your difficulty; but you give us no clue to your failure. What paper do you use? How long before use do you make your toning bath? How long do you leave your proofs in it? How do they look before being put in? &c., &c.

THE PHOTOGRAPHIC JOURNAL.

No. 94, Vol. VI.—MAY 15, 1859.

We are strongly of opinion that during the forthcoming season, as connected with practical photography, considerable progress will be made in attaining greater sensitiveness of the dry collodion film. Various well-established facts and observations appear to converge towards this desideratum. As cases in point, we may cite the productions of Mr. Kibble, of Glasgow, and also draw attention to some remarks let fall by Mr. Hannaford, at the recent meeting of the North London Photographic Association reported in our last.

We cannot forbear remarking, *en passant*, on the very *practical* nature of the discussions generally occurring at this modest suburban society, and the earnestness with which the members figuratively throw themselves into them, as evincing the great advantage derivable to the art from the formation of like local associations, not as substitutes for, but as supplementary to, The Photographic Society, acting towards it somewhat in the same relation as the militia corps does to the regular army—a sort of preliminary depôt, in which the awkward squad becomes converted into the trained and skilful operator, and the useless drones are filtered out.

We very recently assisted at the "birth" of another of these useful training photographic colleges, the South London Photographic Society. A report of the preliminary meeting will be found elsewhere in our columns.

We perceive that the *principle* of Fothergill's process appears to be gaining ground, other substances being substituted for albumen, such as metagelatine, gum, &c., the *principle* however being retained by flooding the sensitised plate with the preservative solution, after dilution of the free nitrate of silver remaining on the plate, and *subsequently washing away as much of the preservative medium as remains uncombined with the silver solution.* This point is the very essence of the Fothergill process (whether Mr. Fothergill knew it or not), and whatever modifications may be made in the material, so long as this feature is retained the process must be regarded as a modification of the original suggestion.

This reminds us of another matter upon which we have a few words of remark to make. In a paper read by Mr. Dorrington at the April meeting of the Manchester Photographic Society, that gentleman made some observations, by which it appears that he somewhat misunderstood what he is pleased to designate as our "editorial fulminations of an infallible decision" against the "Raspberry Syrup Process."

Like the man who was astonished one day at finding that he had been in the habit of speaking prose all his life, we are equally surprised at finding that we are accused of having "fulminated." We have however a very strong persuasion that our *thunder* must be of the kind known as *buttered*. But to return to the point in discussion:—we never questioned or doubted that negatives, and good ones too, could be taken by the aid of raspberry syrup, especially by a skilful operator like Mr. Dorrington; but what we felt called upon to condemn was the claim set up to the suggestion of an *advantageous novelty*, with the further addition that there were "chemical reasons" for the employment of this material, which "chemical reasons," by the way, were prudently not quoted. We asserted that "raspberry syrup" was in fact only an inferior kind of oxymel; that any result obtainable by the former would be more surely attained by employing the latter; and that no sound reason could be given for calling it a new, or even an improved process. Had the promulgator contented himself with stating that in the absence of the supply of oxymel he had availed himself of raspberry syrup as a *substitute*, we should have applauded his ingenuity; but in putting it forth as a *new process*, asserting also that there were "chemical reasons" for its use, he fairly threw himself open to ridicule, and we maintain that it was our duty to lay on the lash; there are many, very many practitioners of photography who have no knowledge of chemistry, and placed as we are, as a watchman *on the look out*, it is as much our business to utter a note of warning when we perceive the danger of many being misled, as it is to sound the praises of the *bona fide* discoverer, or to make an attempt to rescue from oblivion a good suggestion when cumbered by other matter that would probably cause it to be hastily cast aside.

In noticing the allusions of Mr. Dorrington, we have not done so with any feeling of annoyance, on the contrary, we are obliged to that gentleman for affording us an opportunity of explaining what we have probably expressed but obscurely on a former occasion; which indeed must have been the case, or so acute an observer would not have been likely to have misunderstood our drift.

We are much amused at the cool manner in which our Paris correspondent, as appears from his letter in our last number, attempts to regard the matter of M. Nièpce de St. Victor's "bottled light" as a settled question, and the accusation of its reception in this country in an uncandid and unphilosophical spirit.

This is not so bad, when further on we read, as quoted from M. St. Victor's communication, "It is then evident that, under certain circumstances, heat may produce the same results *which in my first researches I attributed to light*," and yet it is but very recently, that in attempting to convince Professor Wheatstone of the alleged fact of the persistent activity of "stored-up light," that he made use of *heat* to produce the effect, an effect which Mr. Crookes subsequently demonstrated was as well produced without any insolation as with it. If our readers will turn back to the said letter, p. 114, they will perceive how M. Nièpce de St. Victor pretends to reply to the objections made "by a single experiment."

We assert that it is no reply at all. Does this gentleman presume to declare that because the said tin tube containing, as he contends, the "stored up light" is surrounded by ice, that no evaporation can go on?

Again, why does he call it stored-up *light*, if he asserts that it will not produce the effect through the thinnest of glass or mica? It is clearly invisible, whatever it may be; and as there are at least two of the most important qualities of *light* wanting, we contend that he has no right whatever to assume that it is *light* which acts. We have another suggestion to offer: let him try with his paper-negative his experiment again, but let it be previously *well waxed* to prevent the passage of vapour, and we more than suspect that he will not succeed.

We by no means feel certain that the so-called new action of light may not result in a much more extraordinary discovery, no less an one than that *lusus naturæ* known as "a mare's nest." In short, that "bottled sunshine" is little else than "moonshine."

The certain variations of what is termed *M. Nièpce de St. Victor's* Uranium Process are, as well as the process itself, a rediscovery of an Englishman's or rather a Scotchman's previously published experiments. Our frequent contributor, Mr. Burnett, not only published them long ago, but also exhibited specimens at the meeting of the British Association when held in Glasgow.

We confess that it does excite in us no small degree of annoyance to find how our French neighbours will persist in claiming these suggestions in the face of such distinct documentary evidence of priority of publication by Mr. Burnett as has been set before them.

Palmam qui meruit ferat. In our last we published under this this title some observations on a claim made by Mr. Sidebotham, of Manchester, on behalf of Mr. Dancer, of the same city, to priority of time in suggesting and producing what are known as micro-photographs. We felt bound to do this, believing at the time that we had been the *first* to originate them; and, having many times incidentally asserted as much, we could not let the matter pass unnoticed, without its appearing that we had attempted to arrogate an honour due to another person — a proceeding which we hold in very especial contempt.

We have now only to state that we made the claim in perfect good faith, believing most strictly such was the fact. We certainly never saw or heard of anything of the kind until we personally produced specimens; but, as appears from the report of the meeting of the Manchester Photographic Society in our current number, we were *anticipated by Mr. Dancer*, who executed specimens about twelve months earlier than we did. We trust that this gentleman will excuse the apparent wrong, committed in entire ignorance by us. To those who know us we are convinced that we need say nothing in vindication; to those who do not, we hope the present acknowledgment will make satisfactory amends.

A NEW COLLODION FOR FIELD WORK.

By J. E Mayall.

[Read at the Meeting of the Photographic Society, 3rd May, 1859.]
(Communicated by the Author.)

The prime requisites for a collodion for landscape photography are: — that it shall be stable in its composition, not easily decomposed at the varying temperature to which it is liable to be exposed; that it shall not become troubled by agitation; shall contain within itself the property of absorption of some of the moisture to which it is unavoidably subjected; and that the film, when silvered, shall have good keeping qualities; not liable soon to dry, to fog, to spot, to tear, to come off the glass, or to the thousand and one difficulties to which the landscape photographer is now liable.

The bath, the developer, and indeed every part of the process should be looked at from the point of view that the operator is in the country, far from the succouring aid of the chemist's shop, the advice of friends (which, by the bye, is no great loss), or the accidental obliviousness of some important article left behind in the last hurry of departure.

I may remark I have had these difficulties in view in perfecting the process which I have now the honour to read to this Society.

Preparation of the Pyroxyline.

Red fuming nitrous acid of commerce, s.g. 1·450 (Nitric acid impregnated with nitrous oxide.)	4 ounces.
Water	½ "
Sulphuric acid, s.g. 1·830	5 "
Blotting-paper	100 grains.

Cut the paper into strips and slightly damp it with steam; mix the nitrous acid and water, and then add the sulphuric acid in a bell glass, very *thin*, to stand the heat; put the paper into the acids with a glass rod, and cover up the vessel with a piece of flat glass; let it stand in a basin of hot water until the temperature of the acids reaches 130 degrees Fahrenheit, for twenty minutes; pour out the acids into another glass, and wash the paper as rapidly as possible to get rid of the bulk of the acid, and afterwards allow it to stand under a running stream of water for six hours.

To the acid remaining from the foregoing process add an ounce of sulphuric acid, and then put into it, in small tufts at a time, fifty grains of clean cotton-wool; get up the temperature of the acid to 130 degrees Fahrenheit again; soak half-an-hour; wash the cotton, as before directed for paper, six hours in cold water, and dry at the ordinary temperature of the atmosphere, merely towards the last dry by gentle heat, and when dry, expose the pyroxyline to the rays of the sun for half-an-hour. The increase in weight ought to be at least fifty per cent.

Remark.—As it is difficult to obtain acids of the exact specific gravity above-named, the operator must, for weaker nitrous acid, use a little more sulphuric in proportion; an excellent plan is to try three samples with varying quantities of sulphuric acid, until the exact proportions are found.

Mr. Hardwich recommends 140 degrees as the temperature of the acids, but as he uses much more water and sulphuric acid in proportion to the nitric acid, it can do no harm; but I find on increasing the temperature beyond 130 degrees, there is a loss of weight in the pyroxyline, also it becomes powdery, which is not a good quality for negative collodion.

Observe — the heavier the pyroxyline is from a given quantity of paper or cotton, the better is its quality.

Ether,

Pure or methylated, if well washed and rectified, and not acid, I find equally good; specific gravity ·720.

Alcohol

Should be especially prepared for this purpose. Ordinary alcohol, s.g. ·820, should be well agitated with dry carbonate of potash and chloride of calcium for two days, say an ounce of each salt to one gallon of alcohol, to render it almost, if not entirely, *anhydrous*; then distil over, in a water bath, out of doors. The s.g. of anhydrous alcohol is ·794, but a gravity of ·800 or ·807 will answer. The chemists prepare this, and no one who has not had considerable experience in this operation ought to attempt it. The alcohol thus prepared is almost as explosive as gun-cotton.

Collodion.

Alcohol, anhydrous	2 ounces.
Ether	10 "
Iodide of magnesium	120 grains.
Bromide of ammonium	45 "
Chloroform	2 drachms.

Shake the chemicals well together until the whole is dissolved; should the bromide of ammonium be difficult to dissolve, add a few drops at a time of ordinary alcohol to assist it, but not more. When perfectly dissolved, add 180 grains of pyroxyline from paper, and sixty from that of cotton, agitate well for two or three hours at intervals; try a plate — if the collodion is too thin, gradually add a little more pyroxyline until the proper consistency is obtained. Here it is difficult to give the exact weight of the pyroxyline; for one kind is much more soluble than another, owing to some accidental circumstance in making it.

This collodion will keep excited for two years without any perceptible change, either from varying temperature or when ordinary care is used to keep it from the light.

Remark.—The iodide of magnesium has properties eminently qualified for out-door work. Its easy solubility, particularly in the presence of a salt of ammonia, is well-known to every chemist, and is indeed its chief characteristic to distinguish it from *lime* on the one hand and *strontia* on the other; and being such a powerful absorbent of moisture, it prevents the decomposition of the excited collodion. The bromide of magnesium is even more deliquescent, and is an excellent excitant also where extreme sensitiveness is not required, but not near so rapid as the combination above given.

In order that the amateur and practical photographer may not be foiled in the attempt to put this process into practice, I now give another formula that answers very well—my friend, Mr. Rosling, says better than anything he has tried.

Collodion, No. 2.

Ether, s.g. ·720	20 ounces.
Alcohol, s.g. ·820	16 "
Iodide of magnesium	144 grains.
Bromide ......do.	54 "
Chloroform	3 drachms.

Shake well together; then add sufficient pyroxyline to render the collodion of moderate consistency, say eight to ten grains per ounce; shake well again, and add four drops of a saturated solution

of iodine in alcohol and eighteen grains of bromide of ammonium, or, instead of the latter salt, three ounces of old excited ammonium collodion will bring the mass into working order in twenty-four hours; decant into six-ounce bottles, and hermetically seal them for use.

I may remark, in passing, that the bromides are the true key to the middle tints: if you want excessive detail, as in leaves of trees and opaque objects, use more of these bromides; if you want intensity, use less.

NITRATE OF SILVER BATH.

Nitrate of silver	50 grains.
Distilled water	1 ounce.
Glacial acetic acid	1 minim.
Nitric acid	$\frac{1}{6}$ "
Iodide of Magnesium	$\frac{1}{4}$ grain.

First neutralise the solution of nitrate of silver with caustic potash, and then, for every ounce of bath, with the quarter of a grain of iodide of magnesium, precipitate a small quantity of iodide of silver from the nitrate; well wash the precipitate before adding it to the bulk of the solution of silver; stand a few hours and filter; then for every thirty ounces of bath add thirty minims of acetic acid and fifty minims of nitric acid, so as to render the bath decidedly acid: this bath will keep for any length of time by now and then adding a crystal of nitrate of silver to dissolve the excess of iodide of silver which accumulates in the bath, and every few days add a few drops of glacial acetic acid. A good plan is to refresh the bath with a sixty-grain solution of nitrate of silver, properly prepared according to the formula given, and refresh the bath every night after working. The specific gravity ought to be from eight to ten degrees; if less than eight degrees the bath must be refreshed with additional nitrate of silver.

Once a week expose the bath to the sun's rays for half-an-hour. No other collodion must be used in this bath.

As there is a large quantity of alcohol in the collodion, the film requires to be well set before dipping it into the silver bath.

DEVELOPER.

Two ounces of iron tacks and two quarts of water put into a stone jar with a cover, to which add two ounces of sulphuric acid, and in forty-eight hours a solution of protosulphate of iron will be formed of about the strength required for a developer. Of this solution take ten ounces, to which add two ounces of common acetic acid (thirty per cent. acid) and one ounce of alcohol. One or two trials will indicate if the developer be strong enough. If the image of the camera comes out too quickly on spreading over the developer, reduce it with distilled water till the required strength of the developer is once obtained, and then observe it.

To refresh the iron jar again add two quarts of water and two ounces of sulphuric acid; cover the solution with a lid to exclude the air, and it will be ready when wanted. It will keep better if six ounces of alcohol be added to every two quarts of iron solution, and bottled off and kept in the dark.

ANOTHER DEVELOPER.

Protosulphate of iron	2 ounces.
Distilled water	1 quart.
Alcohol	4 ounces.

Dissolve the iron, and call this the stock solution. To every ten ounces of protosulphate of iron solution add two ounces of common acetic acid (thirty per cent acid); a few drops of sulphuric added to the stock will keep the developer clear from fogging. Always filter the solution just before using.

As the whole of the process is exceedingly sensitive to light, the greatest care will be requisite to exclude stray light, both of the dark room, of the slides, and of the camera. Wash the plates well before fixing.

FIXING SOLUTION.

Cyanide of potassium...	12 ounces.
Water	2 quarts.

Either in a bath similar to the collodion bath, or by pouring on the plate separately. Hyposulphite of soda is a good fixing agent; but I find the negatives fixed with hyposulphite bleach afterwards, unless they are uncommonly well washed.

CONCLUSION.

The practical photographer will at a glance see the value of this process as a whole.

First, his collodion is not liable to decomposition; it is always the same; it contains within itself a powerful corrective of moisture, and consequently of decomposition.

The bath is not liable to fog, as it is always decidedly acid, and requires to be so; it also contains traces of nitrate of magnesia, which is a preservative agent, and enables the plates to be kept a long time moist. The mixture of paper and cotton renders the film much tougher; it will resist any amount of washing.

Should there be any signs of reticulation of the film it arises from the alcohol not being sufficiently rectified, and in that case more ether will be required in proportion to remedy this defect.

I have preferred to give the process just as I work it, no matter how it may jar with any theories or any other practice. My friends who have taken the trouble to work it, some of them in the tropics, others at the antipodes, and others again in the icy regions of Canada, all write of their success; and should the indomitable photographer of this country find in it a process that he can take up and leave off at pleasure, without any of those mortifying failures which sometimes overtake the most persevering, I shall be amply repaid for the trouble I have taken in bringing it before the Society.

COMPARATIVE EXPERIMENTS ON SOME OF THE DRY PROCESSES.

By JOHN DRAFFIN.

[Read at the Chorlton Photographic Association, May 11th, 1859.]

I THINK it is now generally admitted that on journeys for photographic practice, a good dry process is far superior to the great inconvenience of taking out all the apparatus requisite to work the wet collodion process, especially in hot or windy weather.

Now, having for the last twelve months been exclusively engaged in outside practice, as well as cathedral, &c., interior, I, of course, have endeavoured to ascertain with some degree of certainty which of the various processes recommended would suit me the best. Accordingly I made a series of experiments with the following:—M. Taupenöt's, Dr. Hill Norris's, Mr. Fothergill's, the Honey and Raspberry Syrup processes. The result was that I rejected the two latter, and determined to continue my practice with the three first named, which I did for a considerable time, taking three negatives of each subject—one by each of the three methods.

It is not my intention to argue that this, that, or the other process is best, but simply to lay before you as accurately as I can the results given, the method adopted by myself in preparing the plates, the length of exposure in each case, and the degree of light and nature of subject taken; and I purpose illustrating this to you by means of specimen prints. It will, then, be for you to judge which you think the best process to adopt for general purposes. I say, all three are exceedingly good, and especially are they so for out-door practice; in fact, for this purpose there is very little to choose between them when proper care is taken in manipulation. But as I proceed, you will perceive that it is not only for outside photography that a process should be good to make it all that is wanted. I find to a certainty that in places where there is a deficiency of light—as for instance, a thick wood, or the interior of a church or cathedral—that M. Taupenöt's process must take precedence of all others. This I can prove, I think, to your satisfaction, when I state that, a short time ago, a fine old chest was taken out of the wall of the vestry of York Cathedral, where it had been hid for a long time. This chest being a magnificent thing of its kind, I determined to obtain, if possible, a photograph of it, and obtained permission to do so. Accordingly I set to work with three plates—Taupenöt's, Fothergill's, and Norris's. Now, the chest being immoveable, is fixed in a niche in the wall of a dark dismal room, the vestry, and is itself quite black. I exposed each of these plates five hours; the result was that Fothergill's was a failure, completely so—Norris's considerably better—and Taupenöt's the specimen before you, which I think you will admit is a decent thing, considering the circumstances.

Now, on the other hand, outside, I exposed, on the same day, one each of Taupenöt's and Fothergill's, from the same series of plates, prepared at the same time. The "Spires of St. Mary's Abbey, from the City Walls" is the one in question. It was taken at twice; one-half of the picture is by Fothergill's, the other Taupenöt's; the former you will perceive is more exposed to all appearances than the latter. The time given was: Fothergill's, 1 minute; Taupenöt's, 35 seconds; full sunshine—4 inch focus, $\frac{1}{4}$ inch stop, as a proof that the exposure was quick. You will perceive in Taupenöt's that several men who were at work in the grounds are actually taken in the act of filling a barrow, although they had no notion that I was photographing—in fact, I was at least one-eighth of a mile distant. I will now call your attention to three other pictures of ordinary light and shade, viz., grass, trees, masonry, &c. These views were taken immediately after each other—the exposure as follows:—Taupenöt's 45 seconds; Dr. Hill

Norris's, 1 minute; Fothergill's, 1½ minutes; and also to another picture, taken from a great distance, so as to enable me to obtain the various objects of interest a moderate size for a picture, I used a 14 inch focus, powerful lens, with a ½ inch stop. I gave both pictures (right and left) the same exposure, 2 minutes: one is Fothergill's, the other Taupenöt's; the plates used were the ordinary 6¾ × 3⅜, but the prints were cut down to make a stereogram. Now you will see here that there is a very marked difference between the two pictures. The next I would call your attention to is a picture taken by Dr. Hill Norris's and Taupenöt's, the exposure being exactly the same — 1 minute, rather weak sunshine. Very little difference here, but Taupenöt has it. Next, to two interior views of York Minster — one by Fothergill's, the other Taupenöt's. Fothergill was exposed 4 hours, Taupenöt ¾ of an hour, both the same subject — the Nave — only one looks east the other west; the light all came from the south, so that both had the same light. Here you will see there is no comparison. The beautiful view of the South Aisle in York Minster is, perhaps, the best one of the kind I have produced. It is a Taupenöt plate; and you will observe although exposed a full hour, the beautiful window is perfectly given, and has not suffered from over exposure. In this respect I find Taupenöt's process far superior to any other, and here chiefly where I am at issue with those who condemn this process, because if their practice has been confined to country, &c., views, they are not capable of judging the great merits of the process. Comparatively speaking, I am aware that very few interior pictures are done, because of the great and manifold difficulties to encounter. Still, if we want to adopt *the best dry* process, it must be that one which is equally good for interior as well as exterior, and not the one good for exterior only.

Now, from the remarks which have been made here respecting three processes, it will be inferred (and correctly) that I am in favour of the collodio-albumen process. I have no doubt some parties will say, you have not prepared your Fothergill's plates right; you must have let *one or two drops of the four drachm washings fall off one corner* of the plate, or you have washed too much. In answer I beg to say, I think I can manage the *four drachm washing* as expertly as most people; that I can also wash with a ten-grain silver solution; that Keen's collodion is to be had by me as well as by other people; that I know how to make a neutral bath of silver. I not only think, Mr. Chairman, that I can do all this, but have followed in my experiments, all out to the letter. And I think I dare challenge the best practitioner in Fothergill's process to produce for me a good negative, taken in twenty-five to thirty seconds, four-inch focus, three-sixteenth stop, as I saw stated had been done some time since. I have put myself to a considerable amount of trouble and expense in ascertaining the above facts; because, knowing the amount of work I had before me, I was determined to find out and adopt that system best calculated to enable me to get together what I have — some hundreds of negatives of interest to all tourists in Yorkshire, &c.

For the benefit of those who may feel disposed to try their hands at a dry process, and for the satisfaction of others, I will proceed to state the mode I have adopted in preparing the plates by the various processes in question.

Collodio-albumen.

Collodion.—Any collodion will do, provided it is not rotten. Old collodion is the best — and as a rule, I prefer it thin.

Albumen.—To the white of six fresh eggs, or six ounces, add —

Water	1½ ounces.
Liquor ammonia	1 drachm.
Iodide potassium	½ "
Bromide	6 grains.

A bit of lump sugar, say 2 drachms weight.

Beat all up for twenty minutes, or until it will froth up no more — this is best done with a bunch of a dozen quills, a table fork must not be used. Let stand all night, and filter through sponge into a bottle; put a bit of camphor to it, and a little collodion round the cork, and it will keep any time.

Developer.

Saturated solution of gallic acid. This developer is best for beginners.	or	Pyrogallic... 2 grains. Water ...... 1 ounce. Glacial acetic, 20 drops.

Fix with hyposulphate of soda.

For the bath take —

Distilled water	1 ounce.
Nitrate of silver	40 grains.
Glacial acetic acid	30 minims.

Before commencing to prepare the plates, rinse out a glass measure with a lip to it — dont wipe it with a cloth at all — pour off two or three ounces of albumen into it, and have another vessel ready to pour the albumen off the plate into, as it should not be poured back into the same vessel, or it will create bubbles, which the operator will find awkward to get off the plate. Line the kitchen oven with paper, and on the bottom put a clean cloth for the plates to stand on, and proceed as follows:—Before coating with collodion, WARM THE PLATE SLIGHTLY (let those who practice this method, and who are mortified by seeing their good negatives ruined by blistering, take particular notice of this) and coat with collodion, allowing *it to set well*, say half a minute, then sensitise in either the ordinary bath or in the aceto-nitrate; I use the latter, making one bath do for both purposes — sensitising the collodion and albumen film. I take care to keep the bath clear by means of kaolin — or what will suit as well, I find, *fuller's earth* — and perhaps this is a fact worth knowing, as the former article is sometimes difficult to obtain. Take the plate out of the bath and wash for half a minute under a strong stream of water from a tap. This plan of washing I find far superior to the old plan of washing in bowls. By the latter plan the negatives generally were filled with innumerable specks or holes in the high lights and skies; by the former mode this is entirely obviated. Allow the plate to drain on blotting-paper or a clean rag of any sort, while you proceed with another plate, and by the time this is put into the bath, the former plate will be ready for coating with albumen, as follows:—Pour on, say a quarter of an ounce, and let it run all round the plate, pour off into a separate glass, repeat this with a fresh dose, and put the plate in the oven to dry. Mind no dust comes near it now. The albumen may, after all is done, be put back in the bottle again with a little camphor, and may be used over again two or three times. By systematic working eighteen plates may be prepared in one hour, which I should think quick enough for anything, besides the advantage that these plates, after coming out of the oven, will remain good for any length of time, provided they are kept dry. I have no doubt they will keep for years. The only thing to be done next is, when the plates are cold, to dip them into the bath again for one minute, and wash under a strong stream from a tap one minute. Well washing here must not be neglected or stains will follow. They may either be dried as before, or spontaneously; I prefer the former. The advantage of these plates to parties going long journeys must be admitted by everyone. They may take out a quantity not sensitised, and should they become exposed to the light it is no matter, and the atmosphere has no effect (except moisture). By taking out sufficient silver and acetic acid they can sensitise their plates the night before they are wanted without any trouble, and are then sure of good plates; but suppose a party (and I have known more than one instance), going abroad for two or three months, and taking a quantity of sensitised plates with him, how many negatives is he *sure* of bringing back with him out of every dozen plates, I should like to know? Or suppose some jealous Custom House officer insists on smashing his plate box open (that has been done, too). Now, if the plates contained in the box were plain collodio-albumen ones, this would not matter, even if opened in strong sunlight; and, as a proof of this, I show you a plate which has been prepared upwards of two months, exposed to strong sunlight before the second immersion in the bath, has been sensitised six weeks, and it is three weeks since I exposed it in the camera; the length of time given was, with 4-inch focus, ¼-inch stop, sunshine, fifty seconds. Perhaps my friend Hooper will develope it for you.

In developing, care must be taken, and for parties who wish to begin the process, I should recommend them to use the gallic acid as a developer, adding three or four drops of 20 grain solution of silver. I use the pyrogallic generally, because it saves time; with that I can develope my picture in ten minutes. I would also warn beginners not to *over-develope* their negatives; I have seen many a good picture developed to such an extent as to be useless for printing purposes. There is a difficulty, especially to beginners, in judging by candle-light the exact time to stop the action of the developer. Now this plan will be found a good one. Develop till the detail in the shadows are well out, and then fix with hypo.; next day, by daylight, the negative may be brought up to the proper amount of density, and if the exposure has been right a good picture no doubt will be the result. With respect to the exposure in the camera, this so much depends on the quality of lens, the light and nature of the object, that I shall leave beginners to find this out for themselves. I have frequently heard it stated that thin skies are the result of over-exposure. This is quite a mistake. A great deal has been said about the trouble connected with this

process. Now, sir, I find *it the easiest* process to work. There is not that exact amount of care required in washing—you cannot over wash the plates; if you want to prepare a quantity of plates in a hurry, you have not to run for this or that collodion—any will do; and if you have not used your bath for months, and don't know its condition, it does not matter. The great thing to be observed to ensure success is plenty of washing after the last sensitising, attention to the amount of exposure, and care in the developing. Should stains appear on the surface, they can easily be removed by means of a little cotton wool.

Fothergill's Process.

I have adopted the following method in treating these plates. Keen's collodion neutral bath, saturated with iodide is the usual way. In washing I have found it the safest way to dip the plate into a solution of nitrate of silver, say 10 or 12 grains to the ounce. The four drachm washing gives, perhaps, rather quicker results, but not much so; and unless the greatest amount of care is taken, peculiar markings in the negative are sure to take place. If the four drachm method be adopted, it is certainly adviseable not to use the same water twice over, but to pour on an equal quantity of distilled water on each plate fresh. The simplest and best method of preparing these plates, I think, was given in one of the journals some time since by an Edinburgh gentleman, I believe his name was Bell. His formulæ I tried, and found it to answer well; as also that recommended by him for making a collodion for this process, which I found to answer quite as well as Keen's. Perhaps, should this catch his eye, he will favour the public once more with his paper—to those who practice this process it would no doubt be of service. The plates, after albumenising, I allowed to dry spontaneously, and afterwards placed them in a hot oven. The developer used was the ordinary pyrogallic.

Dr. Hill Norris's.

I will glance over the method adopted by me in this process, if I am not taking up too much of your time. Any good negative collodion will do, but it should not be *new*, or sufficient amount of density will not be obtained. After sensitising in the usual way, I wash well the plates, and *immerse* in the gelatine, prepared exactly according to Dr. Hill Norris's formulæ, allowing the plate to remain in this a few minutes. It is then taken out and dried in a warm oven. The only difficulty I have met with in this process is that the film is liable to become detached. This, I have no doubt, depends much on the kind of collodion used; a tough one being the best, as it adheres more firmly to the glass. Great care must be observed in the developement, as should stains take place the film will not bear touching. The developer used for this process is the ordinary pyro-gallic. Fix with either hypo. or cyanide.

In conclusion, I beg to call your attention to a print which has been treated as follows:—The ordinary albumenised paper floated on the *back* on the solution of gutta percha, recommended some time since—the print was washed *five minutes only*, and has been printed nine months, constantly exposed to light. I merely wish to call your attention to the whites in the picture (not many certainly), but considering the amount of washing and the careless way in which it was done, I think it says a good deal for the gutta percha plan.

NOTE ON PHOTOGRAPHING IN THE PYRENEES.

By M. Civiale, fils.

During an excursion to the Pyrenees I obtained two panoramas of the mountains and some views in detail of the rocks and cliffs, which it appears to me may present some interest in a geological and geodesical point of view.

The first panorama, consisting of four proofs, represents a portion of the chain of the Pyrenees, French and Spanish, taken from the Antecade, near Luchon, at a station 6600 feet above the level of the sea. This panorama, comprised within an angle of less than sixty degrees, forms the sixth part of a cylinder, the diameter of whose base is 13,300 feet. The horizontal plane of this base is 4330 feet above the sea-level, and extends from the south-east to the south-west. I focussed upon the mountains, distant about 5000 feet from the camera, so as to bring in distinctly the most distant objects.

The second panorama, composed of three proofs, represents a view of the Maladetta and its glaciers, taken from Venasque, near Luchon. This station is 7660 feet above the level of the sea. This panorama, comprised within an angle of thirty degrees, is a plain. I focussed upon a point about 12,000 feet from the camera. All the distances and measurements of angles are only approximative.

The points from which panoramic views can be taken are not numerous, and are often of difficult access. The photographer is almost always obliged to work under conditions of distance and orientation, which are detrimental to the effect of the panorama he desires to take.

The other views are details of mountains, the chaotic rocks of Gedne, and the cliffs of Saint Jean de Luz. The negatives were taken on dry waxed paper, by a modified process of my own, and with an instrument as portable as could be made. This indication of the manner in which the proofs have been taken will, I think, show what can be obtained in the way of pictorial illustration of the general arrangement of mountain-chains, their forms, fissures, and their glaciers. We can also determine approximatively, from heights already known, the heights of peaks of very difficult access. The heights already calculated will give with the maps the approximative distance from the camera to vertical lines passing through their different summits; measuring the vertical angles of these summits, direct from the station-point, we obtain the approximative heights, by multiplying the line of the base by the line of the vertical angle.

$$h = \mathrm{A\,B} \sin. a.$$

We can also obtain details of the rocks, of natural sections of the glaciers, fissures, cliffs, &c. Lastly, the comparison of the panoramas of mountains obtained by photography with existing maps, will enable us to rectify certain inaccuracies which have crept into these maps.

DECOMPOSITION OF THE OXALATE OF LIME BY NITRATE OF SILVER.

By M. E. Chevreul.

In the work upon proximate organic analysis, to which I have devoted so many long years of study, I am obliged to distinguish as much as possible, by a series of experiments, the nature of each of the species of proximate principles which I have succeeded in isolating from each other, instead of confining myself to deducing this nature from the action of a simple reagent. It is in conformity with this manner of operating that I am able to assert the existence of *oxalate of lime* in the fat of the sheep and the alpaca. But the process I employed was tedious, since it consisted at first in reducing this salt, by means of sub-carbonate of potash, into sub-carbonate of lime and oxalate of potash; then in reducing this latter into nitrate of potash and oxalate of lead; and lastly, in decomposing the oxalate of lead by hydrosulphuric acid. A much more simple process, which I practice now, consists in converting the oxalate of lime into nitrate of lime, and into oxalate of silver, by means of nitrate of silver previously fused, then dissolved in water.

To one part of oxalate of lime, dried at 104 degrees F., and representing two atoms of water, put 2·07 parts of fused nitrate of silver and twenty parts of water. A reaction of from one to three hours, at a temperature of about 212 degrees F., suffices to decompose several drachms of oxalate; and a trituration of a few minutes' duration of several grains of oxalate of lime in the water containing nitrate of silver, suffices to effect the conversion of the latter into oxalate. The oxalate of silver, once obtained and well washed, touched with very weak hydrochloric acid, is reduced into insoluble chloride and into oxalic acid, easily obtained in a crystalline form from the water holding it in solution.

M. NIEPCE DE SAINT VICTOR'S RESEARCHES.

Distinction between the action of Heat and of Light upon the Salts of Silver.

The experiments of M. Nièpce being of so much importance in a scientific point of view, they have naturally attracted the attention of a great many inquiring minds, who have undertaken either to verify them, or to prove what value they really possess. Amongst others, and not the least in importance, are the investigations recently carried on in the laboratory of the eminent chemist Thenard, by M. M. Ed. Bouilhen, and A. Sauvage, in which the experiments of M. Nièpce were repeated with the most scrupulous care and minuteness. The result is as unexpected as it is important. For the results obtained by solarised tubes, attributed on the one hand to the action of heat, and on the other, to the action of light, are due to neither one nor the other, as will be proved in the sequel.

When a tube containing a piece of solarised cardboard, which has been impregnated with nitrate of uranium is opened in the dark, and a piece of paper coated with nitrate of silver is placed upon it, at the expiration of a couple of hours a very sensible reduction is produced on the portion corresponding with the open-

ing of the tube. If some drops of distilled water are previously placed in the tube, the reduction takes place more rapidly; if the temperature is about 176 F. it is effected in about ten or twelve minutes.

If the dry tube be warmed, the action is quicker than when it is cold, but slower than when the tube contains water.

On the other hand, if paper impregnated with nitrate of silver be exposed directly to the action of the vapour of distilled water, the reduction is effected in fifteen or twenty minutes.

Positive paper, which contains an excess of nitrate of silver, gives the same results.

The conclusion from these facts is as follows:—In the first experiment, there exists an action which is accelerated by the vapour of water, and in the second, that the vapour of water alone will cause similar reductions.

Having arrived at this point, the next step that suggested itself was to submit to solarised tubes papers impregnated with salts, irreducible by heat, in presence of an organic body, experimenting as follows:—

A paper imbued with pure chloride of silver, placed upon a solarised tube, a very strong reduction was obtained in about twelve hours. Pure iodide of silver and bichromate of potass gave the same results.

Although these experiments were very conclusive, it was desirable to corroborate them and render them indisputable. Therefore five pieces of paper were taken, washed with distilled water, and then imbued—the first with nitrate of silver; the second with chloride and nitrate of silver; the third with pure nitrate of silver; the fourth with pure iodide of silver; and the fifth with bichromate of potass: they were placed upon a plate of copper, warmed upon a water bath. At the expiration of ten minutes, two papers only were impressed; that imbued with nitrate of silver and that with chloride and nitrate. The others, although heated for an hour, gave not the least trace of reduction.

By this experiment it is evident that the action produced by the solarised tubes upon the sensitive papers is not caused by heat. Nor is it due to the light supposed to be absorbed and stored up in the paper. For if between the tube and the sensitised paper a thin plate of glass is interposed, no reduction takes place, even after ninety-six hours contact.

In fact, the reduction of a sensitised paper, submitted to the action of a solarised tube, is due neither to heat nor a stored-up light, but rather to a peculiar volatile substance, which is developed when certain acids and salts are submitted to the action of light in presence of an organic body.

From researches specially directed to this object for some time past, it is expected that this body, or this very reducible silver, will soon be made known, at least in its properties.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

The ordinary meeting of the above Society was held on Tuesday, the 3rd instant, Roger Fenton, Esq., Vice-President in the chair.

The minutes of the last meeting were read and confirmed, Mr. Malone having first asked whether the gentlemen he had recommended to be added to the collodion committee had been summoned. He was informed that they had, but that Mr. Heisch had declined to attend.

Henry Jenks, Esq., was duly elected a member of the Society.

Mr. Mayall then read a paper upon a *New Collodion for Field Work*. [See page 118.]

A pause ensued and the chairman called upon Mr. Hardwich.

Mr. Hardwich said he had hoped that some other gentleman would have taken the initiative; he had received some of the collodion described from Mr. Mayall, and tested it, and was bound to confess his favourable impression, although there were some points which he thought might be altered with advantage. He could not agree with Mr. Mayall as to his pyroxyline, and had mentioned to that gentleman the impossibility of obtaining blotting paper of an uniform character, there being a great variety even in the same ream. He (Mr. H.) believed that nothing but cotton wool, of the best quality, will make uniform pyroxyline. Another point (a most interesting one) was the mixture of iodide and bromide of magnesium instead of those of potassium, sodium, or ammonium. A gentleman had in the last number of the Society's Journal suggested the use of iodide of calcium instead of iodide of potassium, but had been in the habit of using it in conjunction with the bromide of calcium, therefore we are not sure that the favourable results in Mr. Mayall's case may not be due to the association of iodides and bromides, instead of to the bases; for it was well known that one great advantage in the addition of a bromide was that the collodion did not so rapidly change after sensitising. Mr. Heisch had pointed that out, and he had examined the point very carefully, therefore he asked Mr. Mayall whether he was prepared to say positively that the same amount of stability might not be obtained from the use of the iodide or bromide of any of the alkaloids, instead of the magnesium compounds, for it appeared that the manufacturing of the iodide of magnesium must be a difficult process.

The advantages of the iodide of potassium were known, and the iodide of cadmium was most satisfactory; because, after purchasing them and applying chemical tests, they were found to be pure and good. Mr. H. had experimented with a view of suggesting a ready mode of preparing iodide of magnesium in the laboratory, and it occurred to him that if he mixed solutions in atomic proportions of iodide of potassium and sulphate of magnesia, then evaporated to the crystallising point, and digested the crystals in absolute alcohol, it would leave behind the sulphate of potash.

He had made the experiment, and evaporated the crystals to dry ness, but found the last portion of water driven off with great difficulty, and vapours of hydrychloric acid escape. Upon treating the result with alcohol, he obtained very readily iodide and bromide of magnesium, which he dissolved in collodion, but he could not make that collodion work at all well, and the only idea which occurred to his mind at the moment was, that a decomposition of the iodide ensued in the heating, and had some fatal effect. Mr. H. made a considerable quantity of iodide and bromide of magnesium as he had thought quite pure, but when he came to test it with collodion it would not work.

If iodide of magnesium were prepared by chemists, how were they to make it in a way to ensure its purity? He thought the best thing would be, to establish careful experiments to make sure whether iodide of magnesium has any decided advantage over iodide of ammonium. Mr. H. had examined Mr. Mayall's collodion very carefully, testing its sensitiveness on a very dull day, with an uniform light, and found it more sensitive than collodion prepared with iodide of potassium only. Mr. Mayall said that the bath should contain forty grains to the ounce, which was a decided advantage for portraits, as he obtained very excellent intensity on a fine day with it, but afterwards on trying it for landscapes he found the skies metallic and weak.

Mr. H. rather inclined to the idea at that time that in the hands of the amateur it was not a collodion very easily brought up to the proper printing point for landscapes. Those who worked last week knew what the character of the light was with the strong east wind. The pictures taken then were very weak indeed.

Mr. H. then suggested that some plain, suitable, satisfactory, uniform collodion should be made and tried with different kinds of iodisers, some containing bromide and some only iodide. If any one wished to go abroad to a hot country, by all means let him provide himself with a mixture of iodide and bromide, and he knew that the mixture of iodide and bromide of ammonium had answered well after being taken in alcoholic solution to Australia.

He did not imagine that the bromides would supersede the iodide, or that Mr. Mayall's collodion would ever supersede the ordinary collodion, nor did he agree with Mr. M. in his assertion that the subject of pyroxyline was worn out, for he (Mr. H.) thought it the very essence of the experiment. Notwithstanding the solarisation of which some complained, he thought that the use of bromide was the key to the half tones; but, while adopting Mr. Mayall's other suggestions, cotton-wool should be used for the pyroxyline, and not the ever varying blotting paper.

Mr. Sebastian Davis had prepared collodion, and sensitised it in different ways, but with one he had observed the singular fact, that after keeping it some time, the colour at first apparent afterwards disappeared—the free iodine seemed to be absorbed; and the reason as he thought was the introduction of a certain quantity of bromide of ammonium. The quantity he introduced was small.

If he used iodide of potassium to sensitise the plain collodion there was too much intensity, in whatever manner the pyroxyline might be made—that is to say, he did not get that amount of middle tint which was absolutely necessary for a perfect picture.

He found in practice that the employment of iodide of potassium in combination with iodide of cadmium gives a satisfactory result, and theoretically arrived at this conclusion. Iodide of potassium however, properly prepared, is not neutral, but slightly *alkaline*, while iodide of cadmium in its pure state has an *acid* reaction, and the two together produce a neutral mixture. In introducing

bromides it was recommended at one time to unite them with iodides in equal proportions, but his observations led him to the conclusion that so large a quantity of bromide tamed down the pictures to too great an extent; he found the most advantageous proportions were about—

$4\frac{1}{2}$ grains of iodide of cadmium,
1 grain of iodide of potassium,
$\frac{1}{2}$ grain of bromide of ammonium.

He particularly mentioned bromide of ammonium, because it was more soluble in alcohol and ether: by mixing in the above proportions with collodion it had, after two or three weeks, become as colourless as water. He remarked there was a collodion which was well known, and is now largely used by some of our eminent photographers, which collodion contains iodide of cadmium, and that was perfectly colourless. As it is a mercantile article he did not otherwise refer to it than by saying it was equal to any in the market for keeping qualities.

With regard to the use of sulphuric acid in the making of pyroxyline, he thought it advisable to obtain the strongest. He had been in communication with one of the largest manufacturers of the article for the purpose of procuring an uniform sulphuric acid, and found that sulphuric acid of specific gravity 1·850 was really purer than that of specific gravity 1·840. A weaker nitric acid is more advantageous, say of the specific gravity of 1·45, as suggested by Mr. Mayall, and as a certain amount of water was added by photographers to the acid mixture, it appeared unnecessary to obtain an acid of very high specific gravity.

Mr. John Williams thought it possible to produce pure bromide of magnesium. He had opportunities of becoming acquainted with the subject: he prepared, first, iodide of iron; to that in a boiling state he added caustic magnesia, until the solution when filtered no longer became black on adding solution of hydrosulphate of ammonia; he then washed it and allowed it to stand twenty-four hours, during which time the excess of magnesia dissolved by the iodide of magnesium becomes carbonated, by absorbing carbonic acid from the atmosphere, and by that time carbonate of magnesia was formed and precipitated; he then evaporated the solution to crystallise, and brought the crystals to absolute dryness in a vacuum, as the operation could not be performed in the open air. The substance formed, if not *pure* iodide of magnesium, is a substance which photographers could use, and is as properly called so as the iodide of ammonium, of calcium, or any of the other iodides used by photographers.

Mr. Mayall had mentioned nitr*ous* acid, a rather indefinite term; pure nitrous acid could not be produced; the nitrous acid of commerce contains chlorine, sulphuric acid, and nitric acid in varying proportions. Sulphuric acid of the specific gravity of 1·84 is, perhaps, that which will keep best.

Mr. Shadbolt found one objection to the use of paper in the manufacture of pyroxyline, viz., that in all samples of bibulous paper that he had used he found a small portion of starch introduced to give it a body.

The developer which Mr. Mayall recommended was an old developer, used, if he recollected correctly, by Martens, of Paris — at any rate he had a manuscript of formulæ in his possession for the last five or six years in which that particular formulæ mentioned by Mr. Mayall appeared.

A remark had been made upon the use of bromides and iodides in combination. At a soiree held recently at the Mansion House he had very carefully examined some specimens by Mr. Heisch, being photographs of red and white camellias and green leaves, in which the various gradations of tone for all the colours were exquisitely preserved: they were taken with collodion containing two equivalents of an iodide for one equivalent of a bromide, by which the details of light and shade in the red and white camellias and in the green leaves were rendered in the most perfect manner possible, and with as perfect a gradation of tone as any photographs he (Mr. Shadbolt) had ever seen. That fact appeared to augur well for the use of the combination of iodide and bromide, where the colours to be taken were violently contrasted.

Mr. Shadbolt had also a question to ask Mr. Mayall: — how could the presence of magnesium in the collodion prevent the absorption by it of water, the salts of magnesium being so greedy of water?

Mr. Malone said that Mr. Mayall told them last meeting "that he had a horror of mixtures," but he had now departed from this fundamental principle. Mr. Malone long ago thought that a very simple collodion, prepared by the Count de Montizon from cotton wool, was the best. He perfectly agreed with Mr. Hardwich in the importance of beginning by studying fully the nature of the pyroxyline. Mr. Murray, he believed, was the first to suggest the use of paper, and it was taken up immediately by Mr. Crookes and others. Mr. Murray used what is called nitrous acid, and although these points had been frequently discussed, he still thought the whole chemistry of the subject required investigation. The objection with regard to paper in the manufacture of pyroxyline was this—that one cannot rely upon having the same substance in paper made even at the same mill, with what would be alleged to be the same materials. In the course of his experiments with Mr. Talbot he spent a fortnight in one of the paper mills, and he found that, unless the whole history of paper were known from the beginning to the end, one could not be sure whether it might not consist of a mixture of linen and cotton in varying proportions; but granting that it might consist of cotton only, even then it might be of new materials or perfectly worn out ones, and if so the result would vary. By using cotton wool you may make collodion as sensitive and as good as any with which we are now dealing. One gentleman had said that it was difficult to get acid of specific gravity, 1.45; but he agreed with Mr. Williams that that was the purest acid in the market—it is prepared by a well-known maker for the assayers, and we are not to conclude that taking a weaker acid, say specific gravity 1.20, it shall be equal to the other with the addition of water.

He (Mr. M.) had been told by a gentleman in the trade that he was satisfied that there was some reason for what the late Mr. Murray had suggested, viz., the mixture of nitrous and sulphuric acids—nitrous acid being the *omnium gatherum* of the acid manufacturer—any old rubbish being put into a bottle and sent out as nitrous acid, and although we were pouring contempt upon this acid, there might be something in its use.

It might be remarked that it was of an orange-red colour—the lower oxides of nitrogen were liberated and absorbed, and after all we ought perhaps to use a mixture of nitric and nitr*ous* acids, and not to attempt to isolate nitrous acid, for in fact we may get hyponitrous acid, which would undoubtedly be a more powerful oxidising agent. Dr. Paris has demonstrated by his delicate starch test, that *pure* nitric acid will not decompose iodide of potassium, showing how different the modifications of nitrous oxides were, and it might be that the mixture of nitric and nitrous acids operated differently on the cotton; he made these remarks to show how very far the subject was from being exhausted.

He might mention that, upon speaking on the subject not long since to Dr. Hoffman, under whose instruction Mr. Malone had studied chemistry, the Dr. had stated that there were five chemical varieties of pyroxyline, and until you ascertained clearly which of those five varieties you were dealing with, no certain result could be produced. Backed by such an authority, he said photographers were at sea upon the whole subject.

Mr. Hardwich said, as Mr. Williams had been good enough to give some information upon the manufacture of iodide of magnesium, he would ask him whether it could be obtained sufficiently dry to be weighed in the scale?

Mr. Mayall exhibited some iodide of magnesium in the required state.

Mr. Hardwich asked how it would keep in alcoholic solution.

Mr. Mayall said very well.

Mr. Hardwich asked whether it could be obtained white instead of highly-coloured like the specimen before him.

Mr. Mayall said that it was white when it was newly made.

Mr. John Williams stated that two or three months since he received twenty-four Winchester quarts of "bottoms" of old iodised collodion from a large manufacturer, for the purpose of saving the ether. Of course it was withdrawn in the usual manner—the residuum was examined and washed to save the iodides present, and upon examining it there was found to be in addition *one pound and five ounces of oxalate of lime*, which was a very unexpected result. Of course it could be seen where the oxalic acid came from, and the collodion must have contained a large quantity of it.

Mr. Hardwich asked whether the change might not have taken place during the distillation of the ether.

Mr. John Williams said it was impossible; he had since tested for it newly-made collodion, there was abundance of oxalic acid in ordinary collodion; he thought the oxalic acid was formed during the process of making the pyroxyline. The collodion was not of Mr. Williams's own manufacture.

Mr. Malone said that sulphuric acid acting upon rags formed a sugar, but in washing the pyroxyline the oxalic acid ought to be washed out by the use of distilled water. If ordinary water containing lime were used it would produce oxalate of lime.

Mr. John Williams said that might be the case, but he should almost imagine that the oxalate of lime would not dissolve in the collodion, but being contained either in the fibre or in the paper it would not be washed out of the pyroxyline.

Mr. Hardwich thought that Mr. Williams's statement was one of very great interest, and it appeared almost impossible that that quantity of oxalic acid could have existed in the collodion. He (Mr. H.) thought that oxalic acid was really formed by aid of the iodide of potassium when distillation was taking place. He could imagine, if iodide of potassium were heated with collodion, that under the influence of the heat the alkaline iodide might bring about decomposition of the pyroxyline. It was a most extraordinary thing, and he could not understand that the oxalic acid was produced in the original manufacture of the gun-cotton; he thought the subject could be pursued further with advantage.

Mr. Mayall stated that he could confirm Mr. Williams in the statement relating to oxalic acid. He (Mr. Mayall), had very frequently discovered it in an old collodion by precipitating it with lime and examining it with the usual tests. That was one of the reasons why he adopted the magnesium in the first instance, for if there were any oxalic acid formed it would be precipitated, and as he now sensitised one or two gallons at a time, he frequently found a very thin film at the bottom of the bottle of white precipitate, which is no doubt a precipitate of that kind, that is, an oxalate of magnesia, or some oxalate of the family; if there were any lime present in the magnesium it would be an oxalate of lime — however, that was a very important fact, and he had no doubt it was one of the clues to the removal of their obscure difficulties, and if no other fact were elicited than that, their time would have been well bestowed in attending the discussion. However, as Mr. Malone had reminded him of an observation he made at the last meeting upon his horror of mixtures, he must deny that what he recommended was a mixture more than was necessary, but was scientifically the best of its kind with which he was acquainted. He thought he might venture to speak from his experience of collodion, having been engaged with it since it was first discovered by Archer, and from the time he (Mr. M.) took his first lessons upon the subject from Dr. Diamond, which he believed was in May, 1851; and he had from that time to the present made nearly all the collodion that he had used: he made it also with the desire that he should each time comprehend some of the difficulties of which he heard others complain and which in the early days of his experience he almost found insurmountable. However, through good report and evil report, and notwithstanding the denunciation of paper, he had adhered to paper the whole of that time; and could only say that whenever he had made a mixture of half paper and half cotton, he had invariably made a finer collodion, flowing more easily over the glass, leaving no reticulation, and adhering better to the glass than when cotton only was used.

He knew Mr. Hardwich in his work recommended an immense quantity of water, and although he (Mr. M.) thought it a useful receipe, he very much doubted whether so large a quantity of water were the best, because he was obliged to use a very large quantity of sulphuric acid to absorb that quantity of water; and although it might act upon the cotton so as to disintegrate it somewhat, he should hesitate in employing that formula, because with it he got a powdery collodion, and consequently a rotten film.

He might state that the blotting paper of which he had shown a specimen was Whatman's prepared blotting; it was the same that is used by the old calotypists; he thought he had used it since 1846; he had never had any difficulty in getting the same quality of pyroxline, either from an old ream that he had purchased years since, or a recent one, which he had obtained lately; he bought it in St. James's Street. They would find that if they took one bundle of cotton and tried to make a batch of pyroxyline with it they would succeed, but from another sample of cotton they would not, and in his opinion there was more difficulty with the cotton than with the paper. They would find that if they made six or seven "brews" of collodion, take one and try it alone, what would be the consequence? They might get a collodion that had perhaps great intensity; if they took another it might produce exquisite detail; another might be tenacious; a fourth powdery; but mix them all together and the whole would be better than either. He would ask, what was that but the same thing as making paper?

Mr. Malone ejaculated, "Never twice alike."

Mr. Mayall must confess, at all events, that the manufacture of *that* paper was very carfully attended to, and he had no hesitation in saying that he could produce a collodion with it which he could work better than any other collodion that he had tried, therefore he should not be beaten out of the opinion that it was good, simply because other gentlemen had *not* succeeded while he had uniformly done so, and he did not recollect a single failure when he had used paper with the proportions and the acids he had named.

In what he had called nitrous acid he knew that there was a large quantity of nitrous oxide. Mr. Hardwich recommended nit*ric* acid— he (Mr. M.) thought there was a great deal of difficulty in using it, and that Mr. Malone's opinion would be found to be correct, viz.— that there were a quantity of lower oxides of nitrogen dissolved in this red fuming nitrous acid, and they were not to take it for granted that it was the refuse of some manufacturer that happened to have an *omnium gatherum* bottle in some dark corner into which he casts all his refuse: however, whatever might be said to the contrary, he recommended that as the acid with which he was successful, and it was the acid with which every one might succeed who tried.

The next thing was Mr. Shadbolt's most important question. He had asked how it was that the salt of magnesium (which was itself so deliquescent) should have the power of preventing the collodion from becoming humid? They all knew that the ordinary collodion contained a large quantity of water — in fact, if they had a very highly concentrated alcohol they could not dissolve enough of iodide of potassium, therefore a small quantity of water must be added; but if common alcohol and common ether were used, they would have in the sensitising compound of iodide and bromide of magnesium, an absorbent of moisture, as they themselves take up six or seven volumes of water to one of salt, without deteriorating (because that was the point); but was that the case with the iodide of ammonium or iodide of potassium? Nothing of the kind; for the moment we add iodide of potassium or iodide of ammonium, a decomposition is set up, hydriodic acid is formed, and the collodion becomes of a pale yellow colour, then red, and finally not capable of being used at all (simply because it, either the ether or the alcohol, had dissolved a quantity of water), and the image became consequently feeble; but one could continue working with these magnesium-excited collodions to a very large extent, one of the advantages being, that if he took a bottle of it sensitised a month ago, another bottle sensitised six months since, and one sensitised two years back, they would all produce precisely the same kind of image. Whether it be the cloudiest weather in winter or the hottest and finest day in summer, the same kind of image would be produced by the different samples; and he asked the gentlemen who had spoken on the subject if they could say the same of any one of the collodions which they knew or recommended — that was the point to be discussed. He had no object in view but the greater perfection of the art—in fact every one imbued with a true feeling for their beautiful art must desire that it should be freed from every possible error that surrounds it.

Mr. Hardwich had made some very important observations — in fact anything that Mr. Hardwich said was always received by the Society as of very great weight, because he had paid a great deal of attention to the subject, and brought an immense amount of scientific information to bear upon it. He wished some of the gentlemen who had time would take the matter up. It was well worth their attention, inasmuch as they could go out into the country under every possible condition of weather and produce a *tolerable* image, and if they used great care they could produce an image which in his opinion could not be surpassed by any other. The uniformity of the production was that which he insisted upon, and he did not think he could say the same of any other sensitiser with which he was acquainted, except iodide of cadmium, which, however, produces a ropy collodion that does not spread readily after the lapse of time, on being frequently poured over the plate and back to the bottle.

Any one could obtain the salt most carefully prepared by Mr. Williams. The salt that gentleman had prepared for Mr. Mayall had worked in the most satisfactory manner, and he had no doubt that many who go forth into the country and come back with smeared plates, very dirty hands, and not many results in the shape of pictures, would go into the country with this collodion and bring back good results, many of them very superior, and have scarcely any failure.

He gave a friend from the West Indies two or three bottles of this collodion, which he took abroad, and a letter had since been received by Mr. Mayall, stating that the collodion was in exactly the same condition as at first, and worked well in that climate. He had also received a letter from the icy regions of Canada which said the same, so that he did not think the theorist should put down a thing that was new until it had been fairly tried.

He offered to assist any gentleman who would take up the matter practically, and stated that as he believed the Chairman was about

to commence a series of experiments upon the subject, he hoped that in November they would be enabled to have some evidence that the magnesium collodion was not a myth, but something which they could all take hold of, and by which they could produce results of which none need be ashamed.

The CHAIRMAN made some pertinent remarks upon the value of the society and such discussions as the present. He then stated his opinion in favour of the combination of bromide and iodide, but that with potassium and salts there was the difficulty that it was almost always settling down in crystals at the bottom of the bottle; whether that arose from defective manipulation or want of knowledge he did not know, and he was always afraid to use collodion with large quantities of iodide of potassium in it.

In following the directions which had been kindly given to him by gentlemen making the theory a study, he had produced a great many bad pictures, more than he would have done if he had followed on in the use of the simple collodion with iodide of ammonium or any iodide easily soluble with the bromides; that of ammonium he had found the most easily worked, the most uniform in its results, and least affected by variation of temperature or climate. All that he had learned he had learned by constant failures, with occasionally here and there a success; and if the method of producing the collodion described to the meeting should prove to be satisfactory, or if Mr. Hardwich, or any of the gentlemen who experimented upon the subject again, would point out a better, the members of the society would, as humble disciples, thank them for their information.

After some remarks from Mr. Malone, who misunderstood the chairman to have undervalued the labours of the scientific section of photographers, which was denied by Mr. Fenton, the meeting was adjourned to Tuesday, 7th June.

Messrs. MURRAY and HEATH exhibited some apparatus described in our last; and the Rev. T. M. RAVEN a proof from a waxed-paper negative, it being the prize picture of the exhibition held in Edinburgh lately. Though very artistic, it was decidedly deficient in detail as compared with good proofs from glass negatives.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

A meeting was held on Monday evening, the 10th instant, at the rooms of the Walworth Literary and Scientific Institution, to organise the foundation of the above-named Society.

Mr. WALL being voted to the chair, proceeded to explain the motives which induced him to convene the meeting, and to state for discussion his views with regard to the proposed Society, which he thought ought to be established in connection with those in the rooms of which the meeting was held.

Mr. SHADBOLT proposed, and Mr. HERVE seconded—

That the present meeting constitute the South London Photographic Society as an independent body; that the subscription be half-a-guinea annually, but to the members of the Walworth Literary and Scientific Institution, only six shillings annually.

After a short discussion Mr. Shadbolt's motion was carried.

Mr. ACKLAND then proposed—

That this Society hold monthly meetings (with a recess), to read papers upon photographic matters, and discuss the same—to organise an Exchange Club—to supply each member with a Photographic Journal periodically, as published, and to present a photograph to each member annually, as soon as the number of members joining should provide sufficient for the purpose.

Mr. HOWARD having seconded this motion it was carried.

Mr. HOOD proposed, and Mr. ACKLAND seconded—

That this Society hold eight or nine meetings in the course of the year, and that ten shillings per evening be offered for the use of a large room, adjoining the Lecture Hall of the Walworth Literary Institution, in which such meetings be held, on the Second Thursdays of the months during the Session, provided that such resolution be confirmed at the next meeting of the Society.

Carried.

Mr. HOWARD proposed, and Mr. LEAKE seconded—

That the First Public Meeting be held on the Second Thursday in June next, in the large room adjoining the Lecture Hall.

Carried.

Mr. ARMSTRONG proposed, and Mr. HOOD seconded—

That Ladies be eligible to become members of this Society.

Carried.

Mr. ARMSTRONG proposed, and Mr. SHADBOLT seconded—

That the following gentlemen be appointed a *Provisional Committee*, to undertake the necessary proceedings consequent upon the formation of the Society, viz.:—Mr. Wall, Mr. Cotton, Mr. Hervé, Mr. Ackland, Mr. Howard, and Mr. Leake.

After some interesting and pleasant conversation relative to the views and objects of the Society just formed, the meeting was adjourned.

Ladies and gentlemen desirous of joining the Society are requested to communicate with Mr. A. H. Wall, 90, Cannon Street West, City.

LIVERPOOL PHOTOGRAPHIC CLUB.

THE ordinary meeting of this Society took place at Mr. Keith's rooms on Tuesday the 5th instant. There was a good attendance of members, and among the visitors was Mr. Holmes, managing director of the Scovill Manufacturing Company, introduced by Mr. Forrest.

Mr. FORREST regretted that he had made no progress with the permanent burning of photographs.

Mr. GLOVER was of opinion that the battery must be laid aside, from the insuperable difficulties in connecting the various insulated parts of most pictures; he would be glad to see some process whereby metallic copper could be deposited by direct chemical and not galvanic action.

Mr. BERRY confirmed this view, and reprobated the use of the battery; though the deepened tone of negatives when subjected to the effect of gold and sulphide of ammonium might give promise of the bold and forcible character of the photograph required, yet it must be borne in mind that all the intensity given by the gold and sulphur was at the expense of the silver, *much* of which was abstracted by this re-action.

Mr. FORREST wished to recall to the recollection of members, the majority of whom could corroborate his statement, that it was unjust to give the credit of taking the first stereoscopic photograph of the moon to Mr. Warren De la Rue, as had been done by the editor of *The Photographic Journal*, in his last number. A large proportion of those present could bear him witness, that so long ago as 1854, he and Mr. MacInnes, after having assisted Mr. Hartnup at the Observatory, had exhibited stereographs of the moon, as well as photographs, upon a disc fifty feet square.

Mr. BERRY presented a remarkable specimen of a photograph, which he held would entirely upset all preconceived opinions upon the phenomena of the calotype. It had been insisted upon on all sides, that the ordinary iodised paper was insensible to the action of light unless combined with free nitrate of silver; now he would exhibit a print that was taken upon paper prepared by the original process of Fox Talbot, and called simple iodised paper, and described by him as wholly insensible to light; this was some he had kept by him fully three months; now, without any subsequent sensitising with nitrate of silver, this had been placed under a negative, and when treated with a solution of pyrogallic acid, strengthened with silver, an exceedingly bold, clear, and distinct image was produced.

Another portion of the same paper, after prolonged exposure to light, was sensitised in the usual aceto-nitrate bath by Mr. Bell, and gave the ordinary calotype negative; thus nothing was gained by this subsequent immersion in the silver, and the latter portions of Mr. Fox Talbot's process were unnecessary.

The Messrs. COOK exhibited some very choice specimens of the turpentine waxed-paper and Fothergill processes, the proofs from which were toned by the formula recommended by Mr. Maxwell Lyte. They were much commended.

Mr. DOYLE showed improved specimens of his peculiar mode of printing.

Mr. HOLMES spoke in very high terms of the superior character of the collodion positives which he had seen in Liverpool, as compared with the American ambrotypes. The most eminent American photographers, he stated, confined their attention to the Daguerreotype and negative collodion processes, the positive process on glass being practised almost solely by those of a lower grade. He also called attention to the attempt of Messrs. Cutting and Bradford to claim by patent the right to the exclusive use of bromides in collodion, a right which will probably be, ere long, contested, as bromides were used in collodion by Mr. Berry,* Mr. Crookes, and others, before the date of their patent.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the evening of the 4th instant, at the rooms of the Literary and Philosophical Society. Mr. Lund in the Chair.

Mr. MANN, the Honorary Secretary, read the following letters to the Society:—

"GENTLEMEN,—At the last meeting of our Society, I claimed for our member, Mr. Dancer, the merit of being *one of the* first to produce microscopic photographs, on account of paragraphs having lately been in the newspapers, claiming for certain parties the invention, and as being something quite new. Mr. Shadbolt, the Editor of *The Photographic Journal*, has replied to my remarks, and calls upon me to give further particulars, as he has always considered himself to be the originator of micro-photographs.

* Messrs. Cutting and Co. date their patent from June, 1853; whereas Mr. Berry lectured on his mode of using bromides in collodion, in April, 1853, at the Royal Institution, Liverpool.

"My remarks are not intended to apply to Mr. Shadbolt, but as he has taken the matter up, I have no option but to reply to his letter: and now claim for Mr. Dancer, not that he was '*one of the first*,' but *the first* who produced these photographs.

"I repeat, then, that I have two specimens of microscopic photographs, given to me by Mr. Dancer, in the spring of 1853; they are mounted with Canada balsam, as microscopic objects, on the ordinary size of microscopic glasses. I may also say that Mr. Dancer at the time informed me how they were taken, and in the autumn of the same year I followed his instructions, and (although not very successfully) I produced some of these minute photographs, and have them still in my possession.

"That there may be no mistake in the dates, I enclose two letters—one from Mr. Dancer, the other from Mr. Binney—confirming my statement.

"*May* 4*th*, 1859." "Joseph Sidebotham.

"*Manchester, May 2nd*, 1859.

"My Dear Sir,—I duly received the letter in which you call my attention to an article on the 'Origin of Microscopic Photographs,' by Mr. Shadbolt, printed at p. 104 of the May number of our Society's Journal; and as Mr. Shadbolt requests you will read his communication to the Society, I must beg as a favour that the members present will listen to the contents of this letter, which shall be as brief as possible, and accept an apology for occupying their time with a matter so purely personal. The question at issue between Mr. Shadbolt and myself is simply this:—Did I produce microscopic photographs before March, 1854? In reply I can state that even on collodion I had produced microscopic photographs in February, 1852; I named these minute pictures, microscopic photographs, and this name I still employ. The word micro-photograph I have no claim to whatever. As the monumental tablet to Mr. Sturgeon was raised in your statement to the Society, and is also alluded to by Mr. Shadbolt, I will confine my remarks more especially to it. The tablet in question was photographed on the 25th April, 1853, and reduced for the microscope early in the following month. Some of the early specimens were presented to E. W. Binney, Esq., F.R.S., F.G.S., &c., of this town; S. Salt, Esq., now of Westport, Ireland; S. W. Williamson, Esq.; A. Neild, Esq.; two of our own members, and yourself. This and other microscopic photographs were well known in this locality long before they had been supplied by me to dealers in such articles; but when they first reached London I cannot say.

"I do not for one moment suppose that Mr. Shadbolt was aware of their existence previous to his own production. To remove all doubt as to the accuracy of the foregoing dates, I enclose a copy of a letter which I have this day received from E. W. Binney, Esq.; this letter relates especially to the tablet in question, and it, in addition to your own testimony, will, I hope (as regards the question of dates), be satisfactory to Mr. Shadbolt.

"I cannot conclude this letter without expressing my great surprise at a statement which appears in Mr. Shadbolt's paper, the substance of which is as follows:—That about March, 1855, Mr. Thornthwaite showed to him a copy of Sturgeon's tablet, which Mr. T. alleged to have procured the production of, in consequence of what Mr. Shadbolt had shown to him. No doubt this has been some misinterpretation, which Mr. Thornthwaite will be able to explain in a satisfactory manner.

"I regret that your friendly feeling should have involved you in this controversy.

"Yours very truly, "J. B. Dancer.

"Joseph Sidebotham, Esq."

"*Manchester, May 2nd*, 1859.

"My Dear Sir,—On referring to my papers I find that it was in April, 1853, when Dr. Joule, F.R.S., myself, and another, got the tablet in memory of our old friend, the late Mr. William Sturgeon, executed by Mr. Latham, sculptor, Manchester. On Saturday, the 23rd of April, I took you to Mr. Latham's place, then in Portland Street, to look at the tablet, and when there, requested you to photograph it for me before it went to Kirby Lonsdale, to be put up in the church. On that same day, Mr Latham, by my orders, took the tablet up to your house in Ardwick. It came back to his place in the early part of the following week, and on Thursday, the 28th of April, it went off to Kirby Lonsdale, and was placed in the inside of the church there. Within a month of the last-named date, in the end of May, 1853, you presented me with a micro-photograph of the tablet, which I received with much gratification and surprise, having expected only a common, and not a micro-photograph from you. I most certainly never gave Mr. Thornthwaite, or any other person, liberty to photograph the tablet; and Mr. Latham assures me that no one but yourself had any opportunity to take a photograph of it prior to its going to Kirby Lonsdale. Believe me to remain, my dear sir, yours truly,

"Edward William Binney.

"J. B. Dancer, Esq., F.R A S., Manchester."

Mr. William Crookes was elected an honorary member of the Society.

The Honorary Secretary stated that Mr. Crookes had sent the volume of the *Photographic News* for presentation to the library of the Society; also a print of his magnified photograph of the Moon, for the Society's portfolio. A vote of thanks was unanimously passed to Mr. Crookes for his presents.

A vulcanised rubber tray, made by Messrs. Macintosh and Co., at the suggestion of Mr. Sidebotham, was shown to the members.

Two large and exceedingly beautiful prints, from collodio-albumen negatives, were presented to the Society's portfolio by Mr. Lund. A very compact exposing camera was exhibited by Mr. Mudd.

Mr. Noton exhibited his contrivance for beating up albumen, and beat up a quantity of albumen in a few minutes into a very solid froth. The apparatus was highly approved of by the members, effecting the object in a most satisfactory manner and with very little trouble. A vote of thanks was unanimously passed to Mr. Noton, for having exhibited the working of the apparatus to the Society.

Mr. Higgins exhibited some sensitised papers which had been kept a month in one of Mr. Mudd's boxes, and which had remained quite white.

Mr. Mudd exhibited one of the boxes contrived by him for the purpose, and explained the same to the members.

Mr. Mabley exhibited some sensitised paper which he had kept white for sixteen days, simply in an ordinary drawer with some chloride of calcium. It was stated that the chloride of calcium would do over and over again, if dried when become damp.

Mr. Mudd said that he intended to make a box for keeping collodio-albumen plates with the aid of chloride of calcium; and it was generally thought by the members that by such a plan the collodio-albumen plates might be preserved longer than it is at present possible to keep them.

Thanks were passed to Mr. Lund for officiating as chairman, and for his donation of the photographs to the Society's portfolio, when the proceedings closed.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

The monthly meeting was held on Wednesday last, the 11th instant, at the Chorlton Town Hall,—Mr. Nicholson, Vice-President, in the Chair.

The minutes of the last meeting were read and confirmed. Two new members were elected.

The Chairman said that a former member of the Association, Mr. John Draffin, who had gone to reside at York, had volunteered to send the meeting a paper on *Comparative Experiments on some of the Dry Processes;* and for the feelings of kindness which Mr. Draffin had expressed for the Society he was under an obligation, and so also must every member be, to that gentleman. He should, without further comment, read the paper, only remarking that the Society was not bound by Mr. Draffin's opinions, with some of which he could not coincide with, but he was always glad to hear and discuss an opposite opinion to his own. [For paper, see page 119.]

After reading the paper, the Chairman invited discussion, which he said must be short, as the time of the meeting was so far advanced.

Mr. Hooper was sorry to differ with an old friend, but he thought Mr. Draffin was wrong in stating that Taupenöt's process was more sensitive than Fothergill's. He also could work both processes, and must be allowed to say, that he found Fothergill's the better for other reasons also; and submitted that the prints by Mr. Draffin proved it, particularly the view of York: the Fothergill side was full of detail and half-tone; the Taupenöt side was without detail in the foreground, whilst the developement had been carried so far that the distance was fading away.

Mr. Fawcett had always found Taupenöt's plate less sensitive than Fothergill's, but much easier to manipulate. The more you washed them the better they were, but could never be got by him in the camera as quick as Fothergill's.

Mr. Wardley thought the collodio-albumen the best process. Mr. Draffin's remarks about collodion and the state of the bath were very good—the dark skies in some of the prints might be caused by a very bright sky and a clear atmosphere; then light objects would take lighter than the sky. He mentioned one case where a white lighthouse was clearly defined against the sky in a picture taken by a friend of his. The subject of developement was not sufficiently studied, he thought, A very common notion was, if under exposed, add more nitrate of silver solution; he thought just the opposite—add more pyrogallic, and give time; forcing was bad, and a good negative could not be got by this means.

Mr. Heywood said that about any state of nitrate bath Mr. Draffin and also Mr. Wardley were, he believed, in error. An alkaline bath would not give good negatives by either Taupenöt's or Fothergill's process. A bath of his that was once acid, had been so doctored with kaolin that it became alkaline, and for some time he could not tell the reason; but by making a new bath all came right, and on testing the old one he found it decidedly alkaline.

Mr. Adin wished that a committee could be formed to try the relative merits of the two processes; but it was thought best that a committee should be formed first to arrange what was requisite to be done to test the matter fairly. It was agreed ultimately that it should be deferred.

Mr. Rogerson brought two negatives and some prints, the first productions of an amateur who had just commenced Fothergill's process, to show what could be done at once by that process: the pictures were not faultless, and the gentleman desired that the errors might be pointed out, so that he could remedy them.

Mr. Whaite exhibited a pair of lanthorns for dissolving views, with a new arrangement for dissolving the pictures into each other by a pair of long combs passing over the lens.

A vote of thanks was passed to Mr. Draffin for his interest in the Society, and for his paper.

The thanks of the meeting were given also to the chairman, which concluded the business of the meeting.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER II.

The Utility of Art Knowledge to Photographers.

One of the most important elements of the picturesque is to be found in the skilful management of light and shadow, or what artists term *chiaroscuro*. Certain effects depend entirely upon a careful arrangement of light; for the object of our photograph may stand out in the boldness of relief, or present a tame, flat, unattractive appearance, according to the attention (or want of it) bestowed upon the management of it.

The photographer desirous of excelling in portraiture must give earnest attention to this subject: the light should fall upon the sitter either from the right or left hand (as the aspect of the studio may decide), and not too strongly or too vertically, but so as to give a soft and delicate gradation of shadow from the upper to the lower portion of the face, and from one side to the other. The portion of the face which is in deepest shadow should be relieved with a judicious amount of soft reflected light, to prevent the black opaque shadows, which are so perfectly unnatural that the merest tyro will at once detect the fault.

Proper contrast in light and shade is always so strikingly effective that it deserves the most earnest attention. In lighting the figure of a sitter we should make our arrangement with the most studious care, not only in reference to the object itself but to the peculiarities of the chemical action of light. Suppose, for instance, a lady wearing black drapery seated upon a scarlet chair, beside a table covered with a red cloth, and before a dark back-ground in the usual subdued light, is the subject you are about to photograph, you will at once perceive that the picture you are about to produce will have a white face, ghastly from contrast, staring out from a dense black mass, swallowing up all the details of dress, figure, chair, table, and back-ground; and therefore you substitute a lighter back-ground, a chair which will relieve the figure, throw the table into deeper shadow, and permit a stronger light to fall upon the illuminated portion of the drapery, thus obtaining in your finished photograph the grandly simple quality which artists term breadth, and the force, roundness, and brilliancy of tone arising from proper contrast and relief.

But while anxious to obtain that relief upon which roundness and force of effect depends, carefully avoid contrasts of too violent a nature: harmony of tone is of no less importance than harmony of colour, or the same principle in music; the lights should melt imperceptibly into shadow, and the shadows graduate gently into darkness.

In arranging your light and placing your sitter you should so contrive that all the prominent features are well lighted: the half tints and shadows will thus find their places upon the retiring surfaces, and due relief be obtained. The strongest light should fall upon the upper portion of your model. Thus, as Fresnoy says—

> "——— from the light receding, or the eye,
> The sinking outlines take a fainter dye.
> Lost and confused progressively they fade,
> Not fall precipitate from light to shade."

How many photographic portraits do we find in which an ill-lighted face and figure destroy the pleasing effect which the photographer's chemical and optical experience and careful manipulation really deserved to compass! All our great artists advocate the vital importance of a proper distribution of light and shade, and the great principles of *chiaroscuro* are of no less consequence to camera pictures than those of the brush and pencil. I have a practical acquaintance with the difficulties to be met with in the chemical action of colours, &c., but studious forethought will go far to meet them; and I am confident that sun pictures can be obtained with *all* the advantages now claimed exclusively for the painter's productions—not easily, I grant you, nor perhaps for the remuneration now given; but as photographs assume higher rank, and take their place in the domain of art, they will readily obtain their fair value.

I cannot now pursue this matter further, but most earnestly advise the photographic student to do so; works upon the subject are cheap and plentiful, and the application of its theory to his practice will call for no great mental effort. Although my present purpose is to assist the colourist, these remarks are by no means unnecessary; for though much may be done by the artist of experience to improve a bad photograph, *it can never be made a really good picture unless it be one in its untouched condition.* I therefore make no apology for the introduction of this chapter.

What further I have to add upon light and shade may be given in a small space.

Pictorial effect is dependent principally upon a quality termed "breadth,"* by which is meant a simple grandeur and beauty of appearance, obtained by grouping together in separate masses the light and dark portions (whether formed by light and shadow or light and dark objects), and, without sacrificing the necessary relief of important parts, avoiding every thing like spottiness or obscureness of effect. One principal light and one principal shadow are preserved to give intensity and brilliancy to the whole. I cannot pause to develope the philosophy of this plan, but practice will fully demonstrate its value. Correggio, Frederico Barroccio, Guercino, and the Carracci used to model figures for their paintings, in order that they might so arrange and illuminate them as to obtain the best effect: why cannot photographers do this also with their living models? The forms and shapes of lights and shadows should be, as a whole, graceful; beautiful outlines should be relieved with light, unpleasant ones lost in shadow; half tints and shades should be skilfully grouped and blended, and the reflected lights carefully observed, for to these we owe that transparency and variation of shadow which, successfully imitated by art, forms one of the most conspicuous charms of our best pictures, but which are too frequently represented in ill-lighted photographs by strikingly unnatural patches of opaque black.

The power of reflecting light of varying intensity is, in the hands of skilful professors, of the very greatest utility. A very capital contrivance for preserving breadth and obtaining relief is found in the use of graduated backgrounds. The pages of a contemporary recently contained numerous plans, of a very complicated, troublesome, and imperfect nature, for obtaining these backgrounds. I forwarded the editor my own method, but the communication was merely acknowledged, its simplicity perhaps begetting some doubts as to its utility.

My homely, but *perfectly successful*, plan is easily described. Having painted the background a warm grey, I paint in or near the centre a circular patch of a very much lighter tint, and with the end of a large brush, held at a right angle to the surface, I tap or stipple the lighter into the darker tint, until the one mingles imperceptibly with the other, and my graduated background is complete.† According as you place this behind the sitter, it may either relieve the shadowed, or spread the light upon the illuminated, portion of the head and figure.

Of no less importance to pictorial excellence is the proper posing of sitters. A beautiful and elegant woman loses half her charms when depicted in a vulgar and ungraceful position, and a man may seem a gentleman or a clown according to the attitude in which he is represented.

Points of resemblance, the embodiment of personal character, age, &c., must of course receive due attention; but more than these are essential to pictorial excellence. Having placed your sitter in an easy attitude before the camera, consider first if it be one most advantageous to the expression of character; examine the outlines formed by the figure to ascertain if there are any formal angles or ungraceful points which can be avoided or rendered less conspicuous, and then endeavour to call forth such an expression upon the sitter's face as may be most pleasing to himself and friends, and in the same proportion to yourself.

Another study of as great importance is that of expression. Some of our great painters demand for one portrait as many as fifty sittings, not of course for mere manipulatory details, but for the embodiment of an expression which should most forcibly depict the very soul as it were of their model. The accomplishment of this lofty aim is commonly held to be the great point of superiority which the painter claims above the photographer; but why? The painter must see the expression before he can paint it, and he must see it more than once: place the same expression before the eye of our camera, and however transitory it may be, the art which can depict a cannon ball in motion will seize and render it at once permanently visible. I know it will be objected that such an expression comes and goes like a lightning flash, and that the process used for portraiture necessarily occupies some few seconds; but my experience teaches me that the expression is dependent upon the feeling, and it is only the more intense feelings (which are never

* I merely use this term here in reference to *chiaroscura*. I shall have to refer to it again in connection with colour.

† Any ordinary house painter will understand this description, and produce the background therefrom.

expressed in mere portraits) which come and go with such lightning-like rapidity. I have seen the most beautiful expressions and the most characteristic upon photographic portraits produced by men who have aimed at something more than "a mere map of the face" (as one of our painters used to call an expressionless portrait), and who produced not only photographs but *pictures.* The great point is to excite the necessary expression in the face of your sitter. Now this is not done by solemnly impressing his or her mind with a nervous fear of moving—better spoil a dozen plates than do this; but endeavour to make the individual to be photographed perfectly at home, and by conversation of a pleasing nature call up such an expression as you may think most characteristic or desirable. It is very common to see photographic portraits of uncomfortable-looking ladies and gentlemen upon whose faces we read at once a feeling of nervous apprehension, as if they were waiting the extraction of a tooth, but these are not less objectionable than grinning likenesses. Should the sitter desire to smile while sitting, the smile should be a faint one; for, however beautiful it may be flitting like passing sunlight over the face, when it is seen fixed and unchangeable it too frequently conveys only the idea of a grin.

Much more might advantageously be added upon the subject of this chapter, but as my real purpose applies rather to colouring than taking photographs, I must refer the more earnest student to the numerous sources of art-knowledge now open to all, rich and poor inclusive.

Letters to a Young Photographer.

No. X.

My Dear Eusebius,

Safely arrived within the sanctuary of your dark room, you will close the door behind you and securely fasten it, lest some thoughtless intruder should incontinently lighten your darkness when you least require it. You are now about to *develope* your picture, if you have got one, for it is not quite certain that you have, although you may think yourself entitled to one, having strictly followed my injunctions. Perhaps there is a screw loose somewhere, and if there be we shall soon discover it.

The developing solution that I usually employ consists of—

Distilled water	10	ounces.
Pyrogallic acid	20	grains.
Citric acid	20	"

For a plate measuring eight and a-half by six and a-half inches, take about one and a-half to two ounces of the above in a graduated glass measure, and holding the plate in the left hand, pour the solution over it so as to cover the surface entirely as quickly as possible. Sometimes the collodion presents a greasy surface; then the developing solution spreads evenly over the surface with great difficulty. If you find you cannot make it cover at once, pour off the solution into the measure, and then pour it on again. It requires some slight degree of sleight of hand to perform this operation skilfully, and no amount of *telling* will make you *au fait* at it; you must try, and if you fail, try again until you succeed.

Supposing all goes well, soon after your developing solution has covered the collodion you will see the picture begin to appear, and gradually become stronger and stronger, until it has attained the full degree of strength desired. The portions of the image that first make their appearance are the high lights; in a portrait they are the linen, the reflected light from the forehead, and other salient parts. You will be puzzled to make out your first picture; when you perceive a grim black-looking visage, looming out of the mist, it will require some little effort of your mind to realise its relationship or identity with the original; but you will gradually come to consider that in your picture the lights and shadows of nature are reversed.

If your picture is very slow in making its appearance, it may be necessary to pour the developing solution off and on several times, and even to add to it a few drops of the nitrate of silver bath. But you will want to know when to stop—when your picture is developed sufficiently, and this is a knowledge that must be gained by experience. As a general rule, unskilled photographers develope their pictures too much, by which they lose harmony of light and shade. If the developing is carried too far, the *darks* become quite dense and opaque, producing a hard raw effect in the lights of the positives taken from them. The negative picture must be examined from time to time, by being held up to the light, or before a taper, the light of which must always be visible through the darkest parts of the image. A picture that is over-developed requires much longer time to print positives from than a properly developed picture, besides being inferior in other respects. The thing is to hit the true medium; for an under-developed picture is quite as objectionable as the one I have described, as it allows the light to pass through it too freely in printing, and the positive will appear dull and heavy, without sufficient contrast between the lights and shades.

As soon as you think you have reached the maximum point of developing, pour off the now dark-brown solution into a recipient for residues (as it contains some silver), and then pour over the picture three or four measures of water, and set it up on one corner to drain on a piece of blotting-paper.

Most of the formulæ for developing that you will meet with substitute acetic acid for the citric acid I have indicated. It is true acetic acid developes quicker, but that is no recommendation with me, for I prefer to have the picture to come out slowly, as it is then under more complete control; besides citric acid is much more economical, it has no odour, it is solid, and therefore much easier to carry about, and what is most important is, it gives pictures of a better quality. The *darks* of a picture developed with citric acid are more transparent than those yielded by acetic acid.

Sometimes the developing solution becomes thick and very much discoloured before the image is completely developed; in that case it is necessary to pour off the solution, rinse the plate with a measure of water, and pour on a quantity of fresh solution.

There are other modes of developing sometimes employed, especially that with sulphate of protoxide of iron. This reducing agent, which has enjoyed various phases of popularity and neglect, is not so manageable in the hands of beginners as the developing agents I have already indicated. But as I know you will not be satisfied to remain in the dark on any point of interest in your art, I will communicate it to you.

You make a saturated solution of pure sulphate of protoxide of iron in cold water; then take of this

Solution of sulphate of iron	10	ounces.
Water	5 to 7	"
Acetic acid	2	"
Alcohol	2	"

You may make any quantity of the saturated solution of sulphate of iron you think proper, by putting into a bottle nearly full of water as many crystals of sulphate of iron as it will dissolve, and then adding a few more, together with a few pieces of iron wire. It will keep any length of time if the bottle be kept corked. The developing solution had better be made fresh every day, as it will not keep long without decomposing. The alcohol is not absolutely necessary, but it serves to make the solution spread more evenly over the collodioned plate.

When this solution is poured over the collodion, the image begins to appear very quickly, but still gradually; if it does not acquire sufficient intensity, pour off the solution, and then pour on to the plate a measure of nitrate of silver of the strength of four per cent., and alternate this, if it be necessary, with a fresh measure of the iron solution. Generally, however, a good picture comes out at once. The advantages in this developing agent consist in its enabling you to secure a good result when the plate has not been sufficiently exposed to yield a picture with the developing agent first-named; therefore it is always employed in obtaining positives on glass. It will also bring out certain details that escape the other developers, such as the details of the beard, or hair of the head in a portrait, dark foliage in a landscape, &c. This mode of developing is by some operators varied in the following manner:—A vertical or horizontal bath is filled with the solution of iron, and the collodioned plate immersed in it—the image appears immediately; then remove it from the bath and wash it carefully, and when the last drop has run off, continue the developing with pyrogallic acid, to which a few drops of solution of nitrate of silver is added. The picture will soon be completed: it is then washed as before indicated. You can also develope with gallic acid. Pour upon the plate a measure of a saturated solution of gallic acid, and as soon as the image begins to appear, pour off the gallic acid into a measure, into which you have previously put a few drops of a neutral solution of acetate of lead, of the strength of five per cent. A white curdy precipitate immediately appears, the whole is thrown on to the proof, and the developement is continued, keeping the plate in constant motion meanwhile. This method answers very well for plates that have been under-exposed in the camera, as it yields tolerably opaque darks.

With all your care it will sometimes happen that your negative turns out weak, whatever developing agent you employ, and it then becomes necessary to strengthen it; this can be done at any time before the plate is varnished. It is only necessary to wash the plate in several waters, and pour over it a measure of a saturated

solution of gallic acid, mixed with about a tenth of its volume of a solution of aceto-nitrate of silver, made as follows :—

Distilled water..............................100 minims.
Nitrate af silver.............................. 10 grains.
Acetic acid .... 8 minims.

Let the plate remain covered with the mixture for a few minutes : the darks gradually become stronger, and the minuter details make their appearance. When the desired vigour is arrived at, pour off the mixture and wash the plate with water. This operation must be carried on in the operating-room, sheltered from the light, and be conducted with great watchfulness, lest the darks become really opaque.

Photographic Glossary.

Laboratory — The workshop in which chemical operations are performed — the operating-room.

Lac — A resin produced by the puncture made by an insect, *coccus lacca*, on the branches of the *croton lacciferum* the *ficus religiosa*, which grows in the East. It is the chief ingredient in sealing-wax and in lacquer. It dissolves readily in alcohol and in a solution of borax. When bleached it is nearly colourless. Its solution in alcohol forms a good varnish for collodion negatives.

Lamp-black — Carbon in the form of soot, obtained by burning resinous substances with a limited supply of atmospheric air. It forms a dense black pigment, used in oil and water-colour painting, and in photography in carbon printing. Mixed with lac-varnish, it is used to blacken the interior of optical instruments, cameras, &c.

Lead — A well-known useful metal. With the acids it forms certain salts which have been employed in photography ; these are the acetate, chloride, and nitrate.

Leather — This substance is sometimes employed as a recipient of photographic images. The first experiments of Wedgwood and Davy were made upon leather. Collodion positives are now sometimes taken upon or transferred to black enamelled leather as a support instead of glass.

Lemon Juice — The juice of lemons consists of water, mucilage, about 5 or 6 per cent. of citric acid, and extractive matter (hesperidin). It is sometimes added to the nitrate of silver solution in positive printing.

Lens — A transparent body, one or both sides of which is curved, and which, according to this curvature, either condenses or scatters the rays of light passing through it. Lenses are generally made of glass or rock crystal, the surfaces of which are either plane or ground spherical, and convex or concave. A lens with both surfaces convex, or with one surface plane and the other convex, or with one surface concave and the other convex, or in general terms, a lens which is thicker in the middle than at the edges, is a *converging* lens ; they are called respectively bi-convex, plano-convex, and concavo-convex or meniscus. A lens with both surfaces concave, or with one surface plane and the other concave, or in general terms, a lens that is thinner in the middle than at the sides, is a *diverging* lens. The judicious combination of these variously formed lenses, produces the achromatic lens, and that other combination termed by the French—the '*objectif.*'

Light — An emanation from luminous bodies, the principal source of which is the sun. A ray of light proceeding from this luminary which appears colourless, or white, is a compound of several colours, which, when decomposed, form the prismatic spectrum. A ray of solar light consists of luminous rays, calorific rays, and chemical or actinic rays ; and it is these latter that produce those changes in bodies submitted to their influence that constitute the principle of photography.

Lignin ; Cellulose—This substance constitutes the fundamental material of the structure of plants, forming a large proportion of the solid parts of every vegetable. It is met with in a pure form in paper, cotton and old linen. Lignin must not be confounded with *ligneous* or woody tissue, which is in reality cellulose, with other substances superadded. Lignin when pure is white, diaphanous, tasteless, insoluble in water, alcohol, ether, and in the fixed or volatile oils. Dilute acids and alkalies exercise but little influence upon it, even at a boiling temperature. Sulphuric and phosphoric acids, when concentrated, attack cellulose, and cause it to undergo remarkable changes ; they transform it first into a substance resembling *dextrine*, then into *glucose*. Fuming nitric acid (cold) combines with it, and forms an insoluble but combustible and explosive substance—gun-cotton (pyroxyline). Boiling nitric acid converts it into oxalic acid. Acetic acid has no action upon lignin. It is not coloured by iodine. In a solution of chlorine it undergoes a kind of combustion. Dr. Schweizer has recently shown that cellulose is soluble in certain compounds of ammonia and copper (see page 80).

Liquor Ammoniæ — Aqua ammoniæ. A solution of ammoniacal gas in water.

Liquor Potassæ — Aqua potassæ. An aqueous solution of caustic potash.

Litmus — A substance employed for colouring test papers, obtained from various lichens. It is of a violet colour, and sold in the form of cakes. The colour of litmus is reddened by acids. Alkalies restore the original colour.

Logwood — A dye-wood. Both water and alcohol take up its active principles. Acids render its decoction of a brighter red ; alkalies produce a purple-blue colour. The salts of iron and bi-chromate of potass throw down a blue-black precipitate, which constitutes the basis of a process for positive printing without the salts of silver.

Lunar Caustic — A name given to nitrate of silver when fused and moulded into sticks of the thickness of a quill. This form of nitrate of silver is commonly adulterated, and should not be employed in photographic formulæ.

Marine Glue — A useful cement for uniting surfaces of glass, &c., said to be composed of caoutchouc and shell-lac.

Mastic — A resin obtained from the *Pistachia lentiscus*, a shrub growing in the Isle of Chio. It is of a pale yellow colour, transparent, dry, and brittle. It is soluble in ether, but insoluble in water. Alcohol when cold dissolves about nine-tenths of the resin, the remainder is soluble only in hot alcohol. Dissolved in alcohol or turpentine it forms a varnish much used for pictures.

New Books.

A Dictionary of Universal Information.
London : Beeton & Co.

We have been favoured with a request to review the above, and as it professes to give *universal* information, of course there appeared nothing extraordinary to us in such requirement, as we naturally concluded that *photography* would form a part of the things treated of, which are legion; but we look in vain for anything connected therewith. This is much to be regretted, for, judging from the style of treatment of those subjects which are included (such as history, biography, geography, theology, mythology, and a host of other *ologies* and *ographies*), the exclusion of photography appears to us to have been a decided mistake.

We can only presume that the proprietors, in sending us a copy of the work, intended thereby to feel the pulse of the photographic community, to ascertain whether the including of matters pertaining to their art would be acceptable. We think there is a very good opening for such an addition, and the various pieces of apparatus would form capital subjects for the numerous wood-cuts with which the work is interspersed.

Foreign Correspondence.

Paris, May 7, 1859.

There can be no question that the present Exhibition of our Photographic Society is the best that has ever been presented to public gaze. Not only in point of numbers (there are upwards of thirteen hundred frames), but also in geographical distribution of contributors is the Exhibition remarkable, apart from the intrinsic excellence and variety of the photographs exhibited. Spain sends *portraits* and *Ethiopian types* from Seville, and fine Roman and Moorish *architectural* subjects from Madrid. From Italy we have fac-similes of nine *drawings* by Raphael, by Alinari Brothers, of Florence ; *sculpture* and architecture from Rome ; *portraits*, printed with nitrate of uranium, from Naples ; from Venice, *views* in Algeria and Spain, *architectural* subjects, and sculpture ; Padua sends *panoramas* of Venice and Milan ; Turin sends *portraits*, and Milan sends *copies* of paintings by the old masters. There are contributions from Pernambuco, Brazil, Bucharest, Mount Caucasus, St. Petersburgh, Mount Athos, Jerusalem, Belgium, Holland, Germany, Switzerland, and England. The photography of the world

may be said to be represented, with the exception of the United States. This gives a fine opportunity for comparison, and, all things considered, the French may be said, if not to bear the palm, at least to hold their own. Of course, mustering in greater numbers, they appear to greater advantage. England is represented by the carbon printing of Mr. Pouncy, by Messrs. Maull and Polyblank, Mr. Roger Fenton, Mr. H. Robinson, and Messrs. Caldesi and Montecchi: these latter gentlemen exhibit their photographs of Raffaelle's Cartoons, which excite the greatest interest among this art-loving people. The French photographers are strongest in portraits and in architecture. Landscape is less cultivated than many other features of the art. There is a very fine series of forty views in the Holy Land, contributed by M. Graham scenes in Corsica, by M. Varin; views in Algeria, by M. Moulin; the Pyrenees are depicted by Mr. Maxwell Lyte and M. Mailand; views in Switzerland by M. de Constant Delessert; views in Egypt and Nubia, by M. de Campigneulles. A great many copies of paintings figure in the Exhibition: among the most interesting may be particularised a series from the works of Hemling and other Flemish painters of the fifteenth century, Van Eyck, Albert Durer, and others.

Of processes, wet collodion seems to be preferred by the majority of exhibitors, although most of the other processes in vogue have their representatives. Very good pictures are presented from waxed-paper negatives. Taupenöt's process has many followers, but I see none of Fothergill's improved method. Many of the exhibitors describe the mode by which the positives are taken. Mr. Maxwell Lyte's views show what can be accomplished by his toning process with phosphate of soda. Some pictures are toned by chloride of platinum. The lens, time of exposure, and developing agent, are also specified by some artists, by which we are enabled to form a comparative estimate of what may be expected and accomplished by each. In one case the negative was produced by the aid of the electric light, but I do not see that any one has made use of Mr. Moule's *photogen*. There are proofs taken with nitrate of uranium. The proofs from Bucharest, very interesting ethnographical subjects, are from negatives taken on waxed linen. Of course all the best French photographers are included among the exhibitors; and the works of Bisson, Baldus, Le Gray, Bingham, Aguado, Bilordeaux, are as readily distinguishable among others as the works of different painters, and this is an enigma which those who regard photography as a mechanical art can by no means readily solve.

Upon the whole, the impression made by the present exhibition is highly gratifying and encouraging. It satisfactorily proves that photography has a special and pecular mission of its own, that it is growing in strength year by year, and taking its place among the graphic arts without disturbing or dislodging others, as was first expected of it. Many a painter who mistook his vocation has become a good photographer, and thus art has become weeded of much mediocrity. I admire the dignified character of the works exhibited; they show that the artists respected their vocation and sought to do it honour. There is a total absence of those punning titles to pictures, and those lame attempts at wit whereby some weak-minded artists seek to provoke the risibility of the groundlings.

Criticism upon works of art I hold to be of no value unless it be made in the presence of the works themselves. Therefore I shall not attempt to convey to you by letter what can be expressed only very inadequately by the articulate word, even on the very spot where are the works that call forth remark. What would it profit you were I to write down that this picture is "beautiful," that "surprising," and the other "charming." You have no mirror of my mind in which those words are reflected in the sense I employ them. Among the crowds of intelligent-looking people, who daily crowd this *pavillon*, the words I most frequently hear are those I have quoted, especially the "charming." These are all expressions of one and the same sentiment — that of gratification or pleasure. Our notions of what is "charming" differ materially, not only among different persons, but also in the same individual, at different periods. For instance, I once thought that red (auburn?) hair and blue eyes, with an aquiline nose, constituted the type of female beauty; but now I incline to the standard of black curling hair, dark-brown or violet eyes, and a *nez retroussé*. Between the blonde and the brunette there are many degrees of difference, and although we may give the preference to the one to-day, to-morrow we may be hopelessly captive to the other. Here I stand puzzled to decide which is the best photographer, or rather which I like best — now it is Bisson, then tis Baldus, next it is Aguado. Among all the one hundred and forty-four exhibitors there is a wonderful individuality; if the good qualities of each could be concentrated in one, then would the triumph of the art of photography be accomplished.

It is not improbable that photographers may soon be able to dispense with light altogether, and, as I have previously suggested, photography itself become superseded by thermography. M.M. Bouilhon and Sauvage have carefully investigated the philosophy of the experiments of M. Niëpce de Saint Victor on stored-up light, and, *mirabile dictu!* have discovered that the results he obtained, and first attributed to light, and then to heat, are in fact due to neither one nor the other, but to a new agent, which has yet to be examined and described, but which M. Paul Thenard at present considers to be *ozone*. But when the experiment that produces the effect attributed to stored-up light is repeated upon sensitised paper, acted upon by *ozone*, the result is wanting. Or to state the matter more literally, M. Thenard made the following experiment. He took a piece of white paper, previously kept in the dark, and exposed it to the vapour of water, and which was not only not solarised, but on its surface all luminous vibration was extinct. The paper was rolled up and placed in a tube, and a current of ozonised air passed into it, and the tube closed. The tube was after a time opened in the dark, and a piece of sensitised paper was placed over the orifice: in a few hours the silver was reduced upon the surface of the sensitised paper, the opening of the tube being well defined in black upon it. This impression could be attributed only to the reducing action of ozone. And yet, what is most singular and perplexing, when a current of ozonized air was passed into a tube containing a sheet of sensitised paper rolled up, no reduction of silver nor impression was produced on the surface of the sensitised paper! Whatever M. Niëpce may have failed in, when attributing the results he obtained to the action of stored-up light, he has the unquestionable merit of opening up a new field of inquiry, and placing even *thermography* upon a new route. I have just learned that Dr. Page, of Washington, has shown that heat is a much more powerful reducing agent than light, and he proposes to print by it not only photographs, but books, and even newspapers! He experimented with a box with double sides, between which he introduced a current of superheated steam. With paper sensitised with iodide of silver, he obtained as many as five hundred proofs in one night, and he could work even quicker than that, if desired, by placing his box upon an iron table, covered with flannel. This result will certainly form a new era in photography. Dr. Page does not claim originality in this application, as similar results were obtained in 1840, by Dr. Draper, of New York. M. Cusco, surgeon, has made an ingenious application of photography of depicting diseases of the eye, which I shall describe more fully in my next. J. P.

New York, 27th April, 1859.

By the annexed scrap, which I have clipped from a daily paper, you will see we *are* progressing in enlarging the area of photography by applying it to useful purposes, and one also to which it was thought next to impossible to apply any process, viz., to hold slippery politicians from falsifying their past acts. It is written in the good book "Thou shalt not speak evil of the ruler of the people," so I must not say a single word of *Mr. Buchanan*, unless I infringe the command.

The Hon. Robert J. Walker has had Mr. Buchanan's letter to him when Governor of Kansas, photographed as a protection against accidents It is full and emphatic on the question of submitting the Constitution to the people, and upon every other point which he subsequently abandoned.

We are great inventors here: about a year ago we invented the art of photographing on wood, and a Mr. Price has received a patent for the process, although some years ago it was in all the journals of Europe. C. A. Seely, A.M., the greatest of all our inventors, has recently been initiated into a "*Supplementary Process*," but no account of it will appear in his journal lest too many should avail themselves of it. Although interesting to the American photographers, it is not at all adapted to *your* side of the water.

As something more interesting to you and your readers, I have very recently seen a stereograph of the moon, produced by an amateur of this city, Mr. Lewis M. Rutherford, of the Second Avenue. I only heard of it two days ago. I have since seen it at the opticians', where it was on view (not on sale), and was astonished at its clearness and beauty. All the details were well made out, and its convexity was perfect. In diameter it fills the stereoscopic field entirely. There was also another of the "half moon," equally clear and distinct as that of the full moon. Both are transparencies on glass, and I was informed that the second picture in each pair was taken at an interval of one month from the time of taking the

first one, so that the base of the two positions is equal to half of the diameter of the earth's orbit. [? Ed.] I shall try to get a copy of it, or them, to send you by a friend who leaves here next week *via* Galway, and who has promised to see a package I send by him safe to the publisher's in Liverpool. In the package will be some specimens of the art as practised here, which will, I hope, compare favourably with those of Europe. The photographs are all printed by young ladies whose names will appear on their several productions. Should clear weather intervene between now and the time the package leaves, one or more *scioptric* views will be sent with it.

Since the death of the *Photographic and Fine Art Journal*, its late editor and a Mr. Davies have brought out a new chemical product for photographers, which, if half what is said of it be true, must revolutionise the whole art. It is called the "ELECTRO-NITRATE OF SILVER." Your stock dealers *must* order it forthwith, or their customers will buy their goods on this side of the Atlantic, and then they may shut up shop.

The immense number of obscene stereographs which flood this market from France is truly awful, and this is rendered more so by the prices at which they are sold—few of them costing more than 1s 6d sterling each. Cheap daubs of groups, from London, are also overflowing the toy-shops at every corner. ARGUS.

Correspondence.

APPARATUS FOR FROTHING ALBUMEN.

To the EDITOR.

SIR,—Seeing in one of your former numbers a description of a machine for frothing albumen, which, however efficient, must be too complicated, cumbersome, and expensive for the generality of photographers, I thought a description of a simple apparatus which I always use might be acceptable.

It consists of a rod of wood, about one foot long and three-quarters of an inch in diameter, one end of which is slit crosswise for two or three inches; into the slits are inserted slips of quill, the ends of which project from the cylinder an inch or more. In this simple form, suggested to me by a friend, the beater end inserted into a jug with a narrow neck or wide mouthed bottle containing the albumen mixture, the upper part of the rod is made to rotate between the flat hands, and thus the albumen is cut and beaten smooth.

I have made the thing more effective by adding a handle flattened at one end. A pin driven into the top of the rod passes loosely through the handle; above the handle a small sheave wheel is driven tight on the pin, and carries the cord of a drill-bow, by means of which the rod is made to rotate very swiftly, thus saving time and labour.

Another plan I might suggest, viz., that any one possessing an Archimedian drill-stock, a tool generally useful in mechanics, might very easily adapt to it a beater of the kind described.

I give above a diagram of the instrument, lest my description should not be intelligible without it.—I am, yours, &c.,

Cheltenham, April 29, 1859. G. S. PENNY.

BLACK VARNISH.

To the EDITOR.

SIR,—Some time ago many and grievous complaints were made about black varnish, none seeming to give satisfaction, either taking a long time to dry, or cracking when dry.

I have for some time past used "Bates's photographic black varnish," which I have found answer capitally. It does not crack, nor is it at all long in drying; and last, but not least, it does not smell so abominably as nearly all other varnishes do.

If you think it worth while to put your readers in possession of these facts, you will oblige by publishing this at your convenience.—I am, yours, &c.

ONE WHO HAS BENEFITTED GREATLY BY THE HINTS WHICH FROM TIME TO TIME HE HAS FOUND IN YOUR JOURNAL.

HOOPER'S TURPENTINE WAXED PAPER PROCESS.

To the EDITOR.

SIR,—How is it that when I dissolve the wax in camphine by the aid of heat, the wax on cooling precipitates itself in small particles?

Should the turpentine or camphine be twenty fluid ounces, or twenty ounces by weight?

I presume the solution must be allowed to cool before filtration. Replies to the above queries will oblige.—Yours, &c. C. H. E. C.

[Hot turpentine dissolves more wax than cold; the wax also may be adulterated with fat of some kind, hence the deposit. Let it subside, and filter when cool. Fluid ounces are those meant.—ED.]

SULPHURIC TONING BATH.

To the EDITOR.

SIR,—In reply to your inquiries respecting my failures with the above, I beg to say, that I use Marion's paper, albumenised according to the formula given in page 25 of *The Photographic Journal*. After pretty long exposure under the negative, the proofs were washed in rain water, to take off the free nitrate of silver, and then placed in the hypo. bath, some for half-an-hour, and others half that time. On taking them out of this, they were again well washed. While in the last water, I prepared the toning bath, into which they were, after a little draining, immediately plunged. They were carefully watched, in expectation that every instant would bring them to the desired colour, but they passed from the red colour given by the hypo. to that of the enclosed, which, you will perceive, has diminished in sharpness from the time in which it was immersed in the sulphur bath, which was about fifteen or twenty minutes.

I tried three different baths, but the result was the same with each. My nitrate bath was of sixty grains silver, with from two and a-half to three minutes floating of the paper. Thanking you for your kindness, and hoping you will be able to solve my difficulty, which I—being totally unacquainted with chemistry—cannot do, I am, Sir, your obedient servant, D.

[By reference to page 61, "D." will perceive, that he has mistaken the *time* during which the proofs should be immersed in the sulphur bath, a few *seconds* being sufficient—from one to three or four, according to the rapidity with which the sulphur is eliminated. After attaining a deep violet and purple colour, the proofs next become black, and if the immersion be prolonged, they become olive green and yellow, and consequently spoiled. No wonder "D." has not succeeded, when he immersed his proofs from fifteen to twenty *minutes*. If the desired tone is not attained in one or two seconds, it may be concluded that something is wrong. Let him try a proof that has been simply washed, and not immersed in the bath of hyposulphite for fixing, until after it is toned, merely to see if the toning does not quickly take effect, not as a practice to be followed. We frequently put proofs into the sulphuric toning bath after simply washing off the free nitrate, and the results are very satisfactory.—ED.]

ALBUMINATE (?) OF SILVER.

To the EDITOR.

SIR,—As some photographers seem bent upon introducing a new term into the chemical dictionary—"albuminate of silver"—it behoves them to see they have good authority for so doing, lest we should some fine day derisively draw upon ourselves another new term—"photo chemists."

The only experiment I have seen published for proving the existence of this chemical compound is that of adding a solution of albumen to a solution of oxide of silver, the resulting precipitate being dubbed albuminate of silver, without any after research to establish the fact.

Now, supposing albumen *pur et simple* does combine chemically with oxide of silver, what is the result of adding it to nitrate of silver?

The albumen unites with the oxide, liberating nitric acid; but as nitric acid also precipitates albumen, another *quasi* chemical is formed, which, I suppose, must be called nitrate of albumen—I should scarcely think the founders of the *albuminous* theory would call it albuminate of nitrogen. Therefore, the film left on the sensitised plate would be albuminate of silver, the other albuminate compound. Now, if we admit the chemical combination with silver, why not also with the other metals, and thus introduce an extensive range of albuminates?

I make no attempt to disprove the chemical affinity. My only object is to protest against the acceptance of an ideal deduction drawn from a simple experiment of there being a new combination of silver, ignored by all the highest authorities on chemical science.

Amongst the great variety of substances that coagulate albumen is tannin. Query—Would this be called tannate of albumen, or albuminate of tannin.—I am, yours, &c.

Islington, May 3, 1859. THOS. A. BARBER.

[Albuminate of silver is clearly a misnomer, as it indicates an acid oxide of albumen united to oxide of silver. It has, however, been clearly demonstrated by Mr. Hardwich that a compound of some kind, sensitive to the chemical rays of light, is formed by the union of white of egg and nitrate of silver: further, that a photograph on albumenised paper consists of metallic silver in combination with albumen, or, at any rate, an organic substance; but what is the exact nature of these combinations has scarcely yet been ascertained. We think the term albumenide of silver would be less objectionable.—ED.]

HONEY PROCESS, &c.

To the Editor.

Sir, — In my communication of the 1st instant (page 115), I omitted to state the quantity of water used with the developer—iron one drachm, citric acid four grains, water four ounces. Your readers will easily recognise it as the formula recommended by yourself in a previous number. I have been experimenting further in the same direction, and enclose a print from a negative by the same process (honey), taken on the 3rd instant — a view of the hustings during the nomination (South Durham) —eleven-and-a-half inch focus, half-inch stop, exposure three-quarters of a minute; circumstances were unfavourable. The light was coming in an opposite direction, shining on the lens in fact — the temporary building being covered with a projecting wooden roof, prevented any light falling upon the "*honourable members and their friends.*" The figures in the "reporters' gallery" (being in front) have been easily identified. The close proximity of other buildings (in one of which I was located), and the focal length of the lens used, prevented me getting a greater number of the "*unwashed*" into the field of view, although it was computed there were 5000 present. From these experiments I have come to the conclusion, that with the same chemicals, a shorter focus (portrait) lens, with Mr. John Brown's (Newcastle) system of stops, and tolerable light, views of moving objects may be taken upon preserved plates, the exposure not exceeding three or four seconds. I am not inclined to give up the previous coating of the plate with albumen, thinking it increases the sensibility — at any rate, it allows of very rough washing, a fault I am addicted to, having a few inches of India rubber tubing attached to the water tap for that purpose; and also does away with the trouble of having to clean plates when you are about to prepare them. I albumenise them in an evening, by the fire side, dry well, and put by for use; give them another warming just before using. I read with much pleasure the interesting discussion on this subject at the last meeting of the North London Photographic Association, and hope ere long to see great improvements in this branch of the art.

On the subject of coagulating the first film of albumen, I find no ill effects from merely drying the plate well. Before pouring on the collodion dip it in the ordinary negative bath (after collodionising), which keeps as good a colour as ever. If it is essential to coagulate the albumen, would not nitrate of silver be preferable to sulphate of iron? The collodio-albumen bath, for instance. The print sent herewith was toned by Le Gray's formula: water, two-and-a-half ounces; chloride gold, one grain; chloride lime, one grain; chloride sodium, one grain. I would recommend double the quantity of water, the action being very rapid; the chloride of lime acts too strongly on the dark parts of the picture. I am not inclined to give up the old plan of toning with carbonate of soda, added to solution of chloride of gold, and used cold.—I am, yours, &c. CAUSTIC.

[The use of *nitrate of silver* to coagulate the albumen would be objectionable, because the compound thereby formed would darken on exposure to light; the sulphate of iron perfectly coagulates without this objection. Our object in suggesting its application was to prevent the liability to *mouldiness* complained of, as regards plates *long kept before use.* But it is of course unnecessary where there is but a short time elapsing before collodionising, and after that operation the silver bath of course effects the object, and the combination with the silver is then unobjectionable.—Ed.]

THE USE OF OLD COLLODION FOR THE COLLODIO-ALBUMEN PROCESS.

To the Editor.

Sir,—A reply to the following will oblige:—

1. Having an accumulation of old collodion of all makes, positive and negative, I put it altogether in one bottle to use for cleaning plates; it occurred to me, however, that it might do for the collodio-albumen process on albumenised plates, being very short in the grain and rotten. I added more pyroxyline; the colour, after sensitising, was pale, so I put in fresh iodising solution to bring it up, and now it seems to work well. A plate steeped in water for six hours, shows no tendency to blister; the only drawback is the presence of structural diagonal markings. The plate was *rocked* on pouring off the collodion, and where the film is thick towards the edge where the collodion was poured off the markings have cracked. Can you suggest a remedy?

2. What is the best method to remove an excess of acetic acid from a ollodio-albumen bath? Will oxide of silver added to it form acetate of silver? which substance is thought objectionable.—Yours, &c. B. J. D.

[1. There is probably an excess of water, which produces the diagonal lines; if so, put into the bottle of collodion some shreds of perfectly dry gelatine, and let them soak; they will swell and abstract a considerable portion of the water, without themselves being soluble in collodion.

Should this remedy not be sufficient, add about ten to fifteen minims of chloroform to each ounce of collodion; the pyroxyline will be partially precipitated, but will re-dissolve by shaking. Lastly, let the collodion set well before immersion in the nitrate bath, observing it by reflection from its surface, and do not immerse it until all crapiness has disappeared.

2. Oxide of silver added will form acetate of silver. A lump of marble dropped in will probably answer the purpose, acetate of lime being formed. But why not add more *nitrate of silver* to vary the relative proportions of silver solution and free acid?—Ed.]

HINTS FOR MANUFACTURERS.

To the Editor.

Sir,—Those of your readers who did not perceive that the diagram in last week's Journal was a printer's error, must set me down as a very vulnerable personage.

I inclose another diagram, which, however, it will perhaps not be necessary to insert, if I describe my idea to be, *one side of the groove perpendicular, and the other to form an angle of about thirty degrees, i.e.,* somewhat after the shape of the letter N

My reason for proposing metal was, that they may be easily cleaned with hot water, and as easily dried.

Another hint is, to make view metres for pictures 8×10, so constructed as to be folded up when not in use; they would save a deal of dodging about with the camera.—I am, yours, &c.

May 2, 1859. AJAX.

[Our correspondent is quite correct in supposing that the comical diagrams appended to his previous communication were errors of the compositor — the fact being, that the note reached us too late before going to press to enable us to see a proof. It fortunately happens that we were "tarred with the same brush," for as "Ajax" was treated to V's, we were served with U's.

We will now give what was really intended by both, viz. —

 and 

Mr. Sparling exhibited at the Photographic Society, about *five years ago,* a folding view meter — as now suggested.—Ed.]

CALOTYPE PICTURES, &c.

To the Editor.

Sir,—In your flattering remarks on my pictures, in your notice of the photographic soirée at the Mansion House, you seem to imply that they are done by the *waxed-paper process.*

Although in these collodion days it may not be a matter of much general interest, yet, for the sake of correctness, I beg to say, that I do not employ the *waxed-paper process,* but the *original process* of Mr. Fox Talbot.—I am, yours, &c. B. B. TURNER.

31, *Haymarket, S.W., May* 6, 1859.

P.S.—What do you think of the Photographic Society and its President being proposed and drunk at the Royal Academy dinner? B. B. T.

[We remember making the same kind of mistake with regard to Mr. Turner's productions upon a former occasion, and were then corrected; but the fact is, the manipulation is so superior to what we generally see in calotypes, that we were thus twice unwittingly misled in judgment.

We are rejoiced to perceive that the artists in colour are beginning to appreciate the value of photography.

They do well: it must be either a friendly assistant or a ruthless antagonist.—Ed.]

ANSWERS TO CORRESPONDENTS.

F. W. Hart.—Received.

Theta.—We really cannot do as you request.

Mary L**e.—Thank you for the compliment and the hint.

Walls.—Possibly your bath is out of order, being too acid; try it with test paper.

Jas. Moody.—See description of Murray and Heath's new water-tight glass bath, in our last leader; it is precisely what you desire.

T.P.—We have not received any previous letters from you on the subject named, consequently we could not have replied. Send particulars.

James Fergusson. — We have already stated that the stereoscopic transparencies of the waves by Mr. Samuel Fry are the best we have seen. See our advertisements as to where they are to be procured.

J. S. C.—1. Burfield and Rouch have a very convenient dark box; so have Murray and Heath, Ottewill and Co., and others. You must choose for yourself according to your requirements.—2. We hardly know what you mean by the most portable plate box; all that we have seen are portable enough. — 3. Herr Pretsch resides at 162, Great Portland Street, W., London.

Fred.—Fothergill's process is not dependent upon a particular collodion, though some kinds are more *convenient* for it than others. We prepared, the other day, four plates with as many kinds of collodion, some being *very* different from others, and were equally successful with all. We found, however, that some were handier to work with. Messrs. Horne and Thornthwaite, and Mr. Alfred Keene, of Leamington, both prepare collodion which they intend expressly for use in this process.

☞ *All* Editorial *Communications,* Books for Review, *&c., should be forwarded to the Editor,* GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal, *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE PHOTOGRAPHIC JOURNAL.

No. 95, Vol. VI.—JUNE 1, 1859.

Amongst our correspondence will be found a communication from Mr. Mayall, in which he notifies some modifications which he has adopted in the formula for making collodion that he considers calculated to keep sensitive, without deterioration, after excitation, for nearly an hour. The paper to which the note refers, it will be remembered, was given at length in our last, and we had it in contemplation to make a few comments upon the subject of it before receipt of Mr. Mayall's note, which however serves legitimately to introduce the matter.

To those of our readers who have little or no chemical knowledge, it may not be very evident *why* collodion, compounded as directed by Mr. Mayall, should remain in a state of exalted sensitiveness longer than any of the ordinary kinds; but when we recal to their minds the first efforts made towards a preservative process, as regards collodion, by Messrs. Spiller and Crookes, in 1854, viz., by washing the sensitised plates with a solution of some deliquescent salt, such as the nitrate of zinc or nitrate of magnesia (both of which were in succession employed by the above-named skilful photographers for the purpose), and hint that in Mr. Mayall's formula the same *principle* is adhered to, though with changes in the method of arriving at a similar end that entitle it to be regarded as a decided novelty, the mystery, if previously existing, is removed.

In the first place, Mr. Mayall makes a plain collodion, containing a considerable quantity of pyroxyline, and that rather of a spongy than of a dense character; and next, by iodising with a salt of *magnesium*, instead of the similar compounds usually employed, the film, on immersion in the nitrate of silver bath, becomes charged, by double decomposition of the ingredients brought into contact, with iodide of silver and *nitrate of magnesia*, the latter salt being precisely that previously employed in a different manner, to the same end, by Messrs. Spiller and Crookes: the utility of this salt consisting in its greed for moisture, thus to a great extent counteracting the usual effect of evaporation.

At the last meeting of the Photographic Society, the discussion arising out of Mr. Mayall's communication was so protracted that time did not permit us to make any rejoinder upon that gentleman's reply to our question, as to "how the salts of magnesium could possibly compensate for the ether or alcohol used in the manufacture of the collodion being slightly contaminated with water?"

Mr. Mayall's reply was to the effect, "that the magnesian salts acted in a similar manner to the chloride of calcium in abstracting the water from the spirituous compound;" but in this supposition he was clearly in error, for chloride of calcium being *insoluble*, can itself absorb moisture like a sponge, and in consequence of its *preference for water* will abstract it from alcohol and saturate itself therewith, whilst iodide and bromide of magnesium, being *soluble* not only in water but in spirit, is quite unable to act in the way contended for.

Mr. Mayall presumes that it is owing to the water usually contained in collodion that deterioration rapidly ensues after iodising; and as he finds that his collodion does not spoil even after being iodised for upwards of twelve months, he erroneously concludes that the permanency is owing to the absorptive power for water exerted by the magnesian compound, forgetting that cadmium salts, which are not deliquescent, enjoy the same immunity from change in the ordinary course of events.

The real use of the peculiar iodide made use of is that we have indicated at the commencement of this article, viz., that when converted into nitrate of magnesia, by interchange of elements in the nitrate of silver bath, its deliquescent properties enable it to replace the water lost by evaporation by re-absorption of water from the atmosphere, or, what is probably more likely to be the case, the deliquescent is sufficient to resist or materially retard the evaporative force.

A point of importance, in explaining the probable cause of some of our hitherto inexplicable failures in collodion pictures, was noticed by Mr. Williams at the last meeting of the Photographic Society.

It appears that, having twenty Winchester quarts of spoilt collodion sent to him for the purpose of recovering the ether, he attempted, after it was drawn off, to save also the iodising salts, and in the course of his operations for this purpose found, to his no little astonishment, that the residuum contained no less than one pound and five ounces of *oxalate of lime*. Such an unwelcome ingredient in collodion is quite enough to account for many of the spots, &c., with which some operators have been pestered, in spite of the utmost precautions as to cleanliness and general care in manipulation. It was mentioned that the *source* of the compound was pretty evident, but some of our non-chemical readers may like to know something more about it.

Whether the pyroxyline be made from cotton or paper, so far as our present inquiry is concerned, is quite immaterial, as in either case *lignine* is employed, a substance which under the action of sulphuric acid becomes converted into dextrine, and subsequently into grape sugar. But nitric acid, acting upon either of the last-mentioned substances, is capable of converting them into oxalic acid; hence it will be seen that during the preparation of pyroxyline it is quite possible that a portion of the lignine may be inadvertantly affording a supply of oxalic acid. Further, if this acid be formed during the manufacture of the pyroxyline, as soon as the same is immersed in water for the necessary washing, provided that the water contains any *lime* in solution or suspension, as is mostly the case, the oxalic acid will immediately unite with it, forming *extremely minute particles of insoluble oxalate of lime*. It would be almost impossible, with any amount of careful washing, to get rid entirely of such a precipitate when once formed; and although it is itself insoluble in ether and alcohol, it would of course be introduced into the collodion with the pyroxyline.

It is but right to mention, that a difference of opinion existed between some of our most eminent chemical authorities, not as to the source, but as to the time of its production—some inclining to the notion that the formation of the oxalate of lime was probably owing to the action of the heat employed to distil off the ether, decomposing the iodising salts and the products acting upon the lignine. We are, however—having listened to the arguments on both sides—persuaded, that the solution first given is the correct one. At any rate, however, we may regard

it as a fact that oxalate of lime does sometimes occur, and that it is certainly injurious.

To be forewarned is to be in some measure forearmed, and this is an additional argument in favour of using tall and narrow bottles for preserving collodion, as any deposit can be more readily left behind with a minimum of waste, and with less danger of disturbing the sediment, in pouring off the supernatant liquid.

In the second annual report of the Blackheath Photographic Society, which we publish in the current number, will be found some remarks which coincide with the opinion we expressed in our last relative to the experiments of M. Niépce de St. Victor, the results being attributed by him to the action of stored-up *light*.

We cannot, however, agree with the report in according to the same gentleman the credit of having *introduced* the uranium printing process, the merit of which we are of opinion is unquestionably due to Mr. J. C. Burnett, of Edinburgh, he having not only published his process *long prior* to the time when M. de St. Victor first directed attention to the uranium salts, but also exhibited at the Glasgow meeting of the British Association for the Advancement of Science specimens of his skill in the actual manipulation of his process. We trust that the gentlemen who drew up the report will look carefully to the records of the meeting quoted, and upon a fitting occasion amend the error.

Relative to the discovery of Mr. J. H. Young, of Manchester, that the latent image upon a collodio-albumen plate can be developed *after* removal of the iodide of silver, which is also noticed in the report, we are in a position personally to give evidence as to the fact that the same phenomenon does occur when the impression is obtained in the camera.

We prepared four plates by a modification of Fothergill's process, exposed them all in the camera for taking landscapes, all being exposed for an equal time; three of them we developed in the ordinary way, the fourth we experimented upon by removal of the iodide first of all, by means of hyposulphite of soda, then washed the plate, and while it was still wet, subsequently developed the picture by means of pyrogallic and citric acids, with of course some solution of nitrate of silver. The picture came out as rapidly and with an image fully as vigorous as those on the preceding three plates, but owing to the fact of our being somewhat eager to ascertain the result of the experiment, we neglected to wash away the hyposulphite of soda as perfectly as we should have done, and the consequence was, an ugly stain proceeding from one edge of the plate towards which the last washing water had drained.

With this exception the experiment was perfectly satisfactory, and but for the imperative and constant demands upon our time we should certainly have repeated the same with greater precaution, to avoid the defect to which we have alluded.

The phenomenon is one that we regard as of the highest importance.

REPORT UPON DEROGY'S PATENT PHOTOGRAPHIC OBJECTIVE LENSES.

In consequence of some observations which appeared in a previous number of this Journal, relative to the lenses above named, we received from Mr. Lloyd Chapman, the agent in this country for the sale of them, a request that we would examine and unreservedly report our opinion of any one of them — intimating at the same time that if we complied with the request, a lens should be placed at our service for such length of time as we might require for the purpose.

A critical examination of one such combination as indicated involves far more labour than appears at the first glance, for each set is equivalent to *six* ordinary lenses, being calculated to produce three distinct portrait and three landscape combinations.

We are so frequently called upon to advise correspondents in matters of this kind, that we determined to accept the task proposed, provided that we should be considered free to publish our opinion whatever it might turn out to be, and with this understanding we commenced operations.

The lens examined was one of size No. 2, for taking portraits $4\frac{1}{4} \times 3\frac{1}{4}$ in., $6\frac{1}{2} \times 4\frac{3}{4}$ in., and $8\frac{1}{2} \times 6\frac{1}{2}$ in.; for views 7×5 in., 9×7 in., and 12×10 in.

In order to accomplish all these variations the construction of the combination is peculiar, consisting of — first, a back and front pair of lenses, each corrected for its special position, and arranged as in an ordinary portrait objective. Instead, however, of these portions *screwing* into the respective ends of the tube, they are adapted to fit in by means of a *bayonet joint*, that by a half turn holds them firmly in place, but at the same time affords great facility for readily and instantly removing either.

With the preceding are supplied also two other supplementary lenses in separate mountings, also adaptable by bayonet joints, viz.— an achromatic concave and a similar convex lens — either of which can be placed *between* the first named normal pair. When so arranged the effect of the former is to lengthen and of the latter to shorten the focus of the original combination, and thus without any change of place, as regards either the sitter or the camera, a picture can be taken of three different sizes.

Again, the anterior combination is constructed to be used alone as a landscape lens, and to this end it is only necessary to remove all the others from the tube, and place the one under consideration at the end opposite to that which it usually occupies. Several diaphragms are supplied, and a fitting place constructed to apply them; but in addition to the diaphragm, the two previously mentioned *supplementary* lenses can also be employed, and thus three variations be made in the focal length of the landscape combination.

Lastly, a very ingenious cap is contrived to fit either the large diameter of the usual sun shade, or the smaller one of the tube above named, by making it double as it were in the cylindrical part.

In all of the above conditions, with one exception specified hereafter, we have not only examined optically the specimen sent, but also taking pictures therewith, and we now proceed to lay the result before our readers.

1st. As an ordinary portrait combination without addition we found the definition good, the field moderately flat, and though not equal to some of our English lenses, quite equal to any French ones that we have tried. The chemical and visual foci agree, as also in *all* the variations of arrangement.

2nd. With the supplementary convex lens, placed between the the two other, the definition is good, but the field not so flat as before, and although the focus is shortened considerably the increase of rapidity of action is but trifling, owing to the additional refracting surfaces of the third lens.

3rd. With the addition of the supplementary concave the definition good and the field flatter, but the increased focal length, together with the additional surfaces, as in the former case, considerably impair the rapidity of action.

4th. The anterior combination alone as a landscape lens — definition fair, rapidity good, field fairly flat, depth of focus considerable owing to an excess of spherical aberration. It is as good as any, and better than most of the French landscape lenses we have hitherto tried.

5th. The above with the addition of the supplementary convex lens in front — definition good, rapidity same as preceding, field moderately flat, depth of focus less than before, but this was more than compensated by superior definition.

6th. No. 4, but with the addition of the supplementary concave — the focal length and size of field covered were greater than we have convenience for taking pictures, consequently we merely examined the centre of the field optically.

As we before remarked, the chemical and visual foci agreed in all the arrangements of parts. The surfaces covered are correctly given. It appears from the above that the supplementary additions are highly advantageous for *occasional* use, and though the results gained are unquestionably not equal to those attainable by the best lenses constructed specially for pictures of any given dimensions, there are many operators who require but rarely to produce large-sized portraits, and whose means are not equal to the outlay necessary for a number of lenses, to whom those under consideration will be highly acceptable.

It must be borne in mind that as *ordinary* portrait or landscape lenses they are unquestionably good, and that the extra ordinary additions are simply substitutes. We think it but just to add that the prices charged are extremely moderate. We must, however, remark that we have tried *but one* set of lenses, though we have no reason to conclude that it was anything more than an ordinary sample, a considerable number having been freely offered for our selection.

In conclusion, we must remark that M. Derogy has adopted an arrangement, either wittingly or unwittingly, that the late Mr. F. Scott Archer employed with considerable advantage several years ago, and one with which he constantly worked to the hour of his death.

REMARKS UPON THE PREPARATION OF DRY PLATES.

By W. Hislop.

[Read at the North London Photographic Association, 25th May, 1859.]

It having been proposed at our last meeting that members should give their especial attention to the dry processes, for the purpose of bringing forward facts for discussion at the ensuing meeting, I take the liberty of offering a few observations, tending to show the direction in which my own experience leads me to expect we shall find the particular method of manipulating most likely to satisfy the desires of the amateur photographer. I do not think that we need busy ourselves in multiplying preservative solutions, inasmuch as the elements of success seem to be the same whichever method we adopt. Good pictures may be got by any process, but we want to know by what method of manipulation we may insure tolerably *uniform* success.

I conceive that no system of partial washing can give uniform results; for even if the manipulation be precise and faultless, the collodion itself is constantly varying from evaporation and other causes, and cannot be said to be precisely in the same condition for any length of time. It follows, that an amount of washing, which will leave a certain quantity of free nitrate under one set of circumstances and with one condition of collodion, will leave a different amount under another set of circumstances and with another condition of collodion. But this is not all. A slight difference of density in various parts of the film will sometimes obtain, causing uneven sensitiveness and stains.

We have then two courses open to us, either to wash thoroughly or not at all, before applying the preservative solution. In either case, care should be taken that the preservative solution, whatever it may be, is as nearly as possible of the same specific gravity as the water in which the plate has been washed, or the nitrate bath in which it has been sensitised. This will facilitate the mixing of the solutions, and the consequent incorporation with the film, and the results will be cleaner and more uniform.

The two methods of preparing dry plates on which I have experimented, with especial reference to this evening's discussion, are modifications of well-known processes, namely, Fothergill's and the oxymel process.

In the first, I find that I have been anticipated by a paper in a recent number of *The Photographic Journal*. It simply consists in using a very dilute solution of albumen, consisting of one part of white of egg to about thirty or forty of water, in which the plate is plunged after leaving the nitrate bath, being first drained and the moisture removed from the back. After about two minutes it is taken out, well washed, and dried.

The second plan has been published by Mr. Llewellyn. The plate is well washed under a tap after sensitising, and then immersed in a bath of iodide or bromide of potassium, containing five grains to the ounce of water. It is again washed to remove all trace of potassium compounds, and then has the preservative solution poured over it.

This is composed of half a drachm of oxymel, half a grain of citric acid, and three-quarters of a grain of nitrate of silver to the ounce of water. This solution may be used over and over again, and therefore a single ounce will go a long way. After the solution is poured on and off several times, the plate is set up to dry. I find in all cases it is desirable to dry the plates with moderate speed. I effect this simply by ranging them on edge on a shelf, filling a few old wine bottles with hot water, and placing them in a row before the plates. In a short time they will be ready for the camera.

As to the results of the two plans, I find that the first, or modification of Fothergill's manipulation, so far as I have tried it, gives very uniform and satisfactory results. The second gives a surface which is perfectly dry and hard, is also very sensitive, and *quick in developing*. The resulting picture has a remarkably even sky, and possesses good artistic qualities. There is one drawback: the film seems completely detached from the plate; but if the glass be previously *coated with dilute albumen*, this defect is perfectly remedied.

As to keeping qualities I am unable to speak from experience, not having kept plates for a sufficiently long period to speak positively, but I see no reason, from analogy, to doubt the capabilities of either plan in this respect.

REMARKS, &c.

By Alfred Keene.

Remarks upon "Amateur's" Communication of May 1st, and a Reply to Mr. Draffin's "Comparative Experiments of some of the Dry Processes," and "A Modification of Fothergill's Process, by which Sensitiveness is Increased."

I am again putting in an appearance on the "Fothergill Process" subject, even at the risk of the dire displeasure of your correspondent "Amateur;" not that his remarks are of themselves of sufficient importance to call forth a reply, but feeling occasion to do so to Mr. Draffin's paper, I will, *en passant*, notice the former also. With respect to the part relating more particularly to myself, and referring to my communication of April 1st, it is quite true that much therein contained had, at *various* times, previously appeared, but at the same time, much is given that had *not* before been made known, and a knowledge of which will, *under the circumstances named*, facilitate the successful practice of the process.

"Amateur" appears to have fallen into a mistake in supposing that because I have minutely detailed how the process may be practised with the *greatest success and certainty under almost every probable variety of circumstances*, it is not simple and easy. The precautions there recommended as regards state of operating-room, and use of artificial heat, are equally applicable, *under the same circumstances*, not only to the modification given by Mr. Lloyd, but *all* similar dry processes, including the Taupenot; they are however *not* necessary (with exception of draining on glass, which I would at all times advise) in summer, when the temperature is high and the plates dry quickly; the original simple instructions are then *ample*.

I have no desire whatever to disparage the mode of manipulation recommended by Mr. Lloyd (with a second edition of which "Amateur" has favoured us), for it is certainly very good. "Amateur" however errs, when he states that plates so prepared are *more* sensitive, as also in representing it so much more simple than that detailed by me. I have long since tried (when first experimenting on the process, and at a time when scarcely half a dozen knew of it—I may safely say before Mr. Lloyd—though all credit for any advantage it may offer is certainly due to him for publishing it), and found it answer exceedingly well, but the one I recommended equally so, both as regards sensitiveness, ease of manipulation, and certainty of result, and possessing the *additional advantage* of a *tougher and firmer film*, for which I considered few would object to the extra fifteen or twenty seconds required.

In his developing directions "Amateur" has departed from Mr. Lloyd's original, so far as relates to allowing the solution to remain *quite still* till details appear; this I have always found to produce ripple or wave-like dark deposits.

Now to the chief object of my communication, viz. — a reply to Mr. Draffin's comparative experiments.

The best possible *refutation* of inferiority of the "Fothergill process," intended to be proved by his paper, is the discussion that ensued on the reading of it, among the members of the Chorlton Society, more particularly the remarks of Mr. Hooper, who, with other members, not only gave testimony to the *superior* sensitiveness of Fothergill's over Taupenot's, but also that the *very specimens sent by Mr. Draffin to illustrate inferiority of former*, and superiority of latter, *proved the reverse*, the Fothergill specimen being full of *half-tone* and *detail*, while the Taupenot was *without* detail in the foreground; besides, in the latter, *developement was carried so far* that distant objects were almost lost.

The following, extracted from the many communications I have received, fully bear out the above:—

FROM CHESHIRE.

"I believe I have got *better definition* and *finer gradation of tone* by this process than any other I have ever tried, *the wet not excepting*."

GLOUCESTERSHIRE.

"Of all the dry processes which have appeared, none in my opinion, come up to the Fothergill, and I believe few amateurs have experimented more."

GLOUCESTERSHIRE.

"I followed implicitly your instructions, and my success was astonishing to myself; the *first day* I got pictures equal to any I ever saw. * * * I must say, again, with regard to success it is certain."*

In addition, I beg to enclose you a specimen — my own experiments being upon such uninteresting objects as the tops and backs of houses, &c., with the addition of tops of two or three trees — with which I was favoured by Mr. Ebbage, an amateur, whose success fully corroborates all that has been said in favour of the "Fothergill process." The specimen is soft, and full of half-tone; the water of the brook is entirely free from the harsh whiteness so fre-

* Mr. Keene has communicated to us the names of the writers of the letters from which the above extracts are taken.—Ed.

quent, and possesses every variety of shade; the grass on the bank is sharp and *well out;* while the distant trees, seen under the arch of the bridge, are not at all obscured.* The exposure was forty-five seconds, Ross's landscape lens, stop and focal length as described by Mr. Draffin. It may however be very justly said, this is neither twenty-five nor thirty seconds. True; but if a picture, chiefly foliage, can be obtained in the time named, few, I think, will doubt the possibility of obtaining one, in the shorter time, under the most favourable circumstances as to light and object photographed, as I have myself witnessed.

Mr. Draffin lays much stress on the advantages the Taupenot plates offer to those going on long journeys; this I maintain is quite a fallacy. Did the Taupenots possess the advantages enumerated of *non-injury*, by keeping or *exposure to light, when ready for use* the case would be altered; but to be obliged to take all the necessaries for sensitising, washing, and, if long away, developing, &c., equalling every thing, except collodion, required for the wet process, to say nothing of obtaining conveniences for performing these operations from home, certainly cannot be so very advantageous.

Mr. Draffin also lays some stress upon what he considers another advantage, viz.—the kind of collodion used for Taupenot's process not being of much importance—in fact, that any kind will do. My experience certainly runs counter to his here, having always found it difficult to meet with one that does not give blisters; for though one day it may not do so, yet the next, from some change in the state of the atmosphere or temperature, they may be far too plentiful, and the collodion most suitable is unfit for any other process. The reverse of this is the case with the "Fothergill," not only as relates to blisters, but the collodion suitable for it answers equally for the wet process.

In ease and celerity of preparation the Fothergill again has considerably the advantage. In preparing a Taupenot plate, it is sensitise, thoroughly wash with plenty of water, coat with albumen—here great care is required, to avoid air bubbles—dry, bake; then again sensitise, thoroughly wash with plenty of water, and dry. To prepare a Fothergill plate—Sensitise, dilute bath on surface with measured quantity of water (care required, that it may be done evenly), coat with albumen, well wash and dry; or, as suggested by Mr. Lloyd, sensitise, flush with *dilute* albumen, wash and dry; or where sensitiveness is not an object, sensitise, place plate for a minute in a basin of water, coat with albumen, wash and dry.

Developing—Here also the Fothergill has a decided advantage in the comparative shortness of time required, varying in summer from three to five or ten minutes, and in winter from fifteen to sometimes near sixty.

It is quite true many have failed with the Fothergill, but this has also been the case with every other process. Some have washed too much after sensitising and before coating with albumen, and so lost sensitiveness, which easily accounts for the discrepancies met with as to sensitiveness of process. Others, who have used the proper quantity of water, have either not continued it on long enough, or not carried it equally all over the plate, and so had stains. To ensure success, however, no more care and attention are necessary than in the practice of photography generally.

With these remarks I leave the Fothergill process in the hands of the photographic public, feeling confident that as its growth in public estimation has been, so it will continue, *excelsior! excelsior!*

In the above I have not taken into account the modification by which sensitiveness is so much increased; for though further favouring the Fothergill, yet not being known at the time Mr. Draffin made his comparative experiments, I have thought it not fair to take advantage of it in replying to his paper.

As many of your readers may probably not have seen the accoun of it sent by me to a contemporary, I will, with an apology to "Amateur" for the repetition, insert it here. A short time since a correspondent, who gave his initials only, called attention to the accelerating effect of muriate of ammonia added to the albumen; upon trial by myself and others, such proved to be the case, I think I may safely say, doubling it. No particulars were given, but the quantity I have found answer best is six grains to the ounce of either prepared albumen, or equal parts of white of egg and water (the former I prefer, as a quantity may be prepared at once, the ammonia preserving the albumen). The mode of manipulation is in every respect the same as without the addition.

I have also found a still further acceleration of sensitiveness by substituting for the albumen thin gum water, as follows:—White gum-arabic, ten drachms; muriate of ammonia, thirty-five grains; dissolved in six ounces of distilled water. This is to be used *instead* of prepared albumen, and in the same manner.

* The specimen fully bears out the description.—Ed.

SUBSTITUTE FOR COLLODION—CELLULOSE.

Since the discovery of a convenient solvent for cellulose, by M. Schweitzer (p. 80), the efforts of scientific photographers have been directed to making it available as a substitute for collodion, by which much of the uncertainty attendant upon the use of that complex body may be avoided. M. Van Monckhoven has addressed a letter to the editor of *La Lumière*, detailing his method of preparing the new vehicle, and the results attending its use. He employs a solution of cellulose (carded cotton) in ammonio-oxide of copper (oxide of cuprammonium). The oxide of copper may be prepared in the following manner:—In ten or twelve *litres* (17½ to 21 pints) of water, retained in a glazed or wooden vessel, dissolve one and a-half kilogrammes (3 lbs. 5 oz.) of commercial sulphate of copper. In another vessel dissolve one kilogramme (2 lbs. 3 oz.) of caustic potash in its weight of water, and then mix the two solutions together. The liquid becomes a bluish green mass, but by stirring it quickly with a glass or wooden rod, a precipitate falls to the bottom of the vessel, and in a few hours the supernatant liquid becomes clear. The liquid is drawn off by means of a syphon, and fresh water is poured upon the precipitate to remove the foreign salts (sulphate of potash or potassa in excess). After a few hours of repose the liquid is again decanted. This washing must be repeated three times, in order to obtain the oxide of copper quite pure; the deposit is finally placed in a linen strainer to drain; at the end of four and twenty hours the mass takes a pasty consistency. It is then removed from the strainer with a tin spoon or a plate of glass, and put into a wide-mouthed jar, and ten litres (17½ pints) of commercial aqua-ammonia poured on to it. The ammonia must be free from colour. Upon shaking the jar all the oxide of copper becomes dissolved, and forms a liquid of a splendid deep blue colour. After reposing twenty-four hours, decant off, say one litre, and put into it 100 grammes (3½ oz.) of carded cotton: that employed for polishing daguerreotype plates is excellent for the purpose. The liquid is shaken at intervals until the cotton is all dissolved, which is effected in a few hours; it is then diluted with a fourth of its volume of water. This forms the substitute for collodion. Its preparation may be stated by the following formulæ:—

No. 1.	Sulphate of copper	3 parts.
	Caustic Potash	2 „
	Water	10 to 20 „
No. 2.	Liquor ammoniæ	20 „
	Carded cotton	2 „
	Oxide of copper obtained from No. 1.	

The method of preparing the ammoniacal oxide of copper, as indicated by M. Peligot, is perhaps simpler than the above; it is as follows:—

Into a long narrow glass funnel, loosely covered with a piece of glass, put some pure copper turnings or filings, mixed with an equal quantity of fragments of glass, a portion of which should first be placed in the funnel, so as partially to choke the passage, and cause the liquid put into it to flow through slowly. Place the funnel in a large bottle, and pour over the copper a sufficient quantity of *liquor ammoniæ*. The copper, in contact with the ammonia and the oxygen of the atmosphere, is converted into oxide of copper, which the ammonia immediately dissolves, forming a blue liquid. When all the liquid has passed through the funnel it is allowed to remain for an hour for the copper to become completely oxidised, and then a fresh portion of *liquor ammoniæ* is poured into the funnel, repeating the operation until the liquid has acquired an intense blue colour. In this liquid the cotton is dissolved, as indicated above.

It is essential that the ammonia, in passing through the funnel, should flow into the bottle only drop by drop, else it will be imperfectly saturated with oxide of copper; and it must be allowed to settle before the cotton is dissolved in it, to avoid impurities. As the odour of ammonia is very disagreeable, this operation should be performed in the open air.

It is very important that this liquid be carefully prepared. To test it, pour a small quantity on a piece of glass—it should flow and spread itself slowly and regularly. With a solution that is too fluid no good result may be looked for.

This fluid is iodised with about one or two per cent. of iodide of potassium, dissolved in twice its weight of water. The glass plate is covered with it in the same manner as with collodion; the excess may be allowed to drain off on to a piece of blotting-paper, resting the plate against the wall. As soon as the liquid ceases to flow, plunge the plate into the following nitrate bath:—

Distilled water	100	parts.
Fused nitrate of silver	100	„
Glacial acetic acid	50	„

the film becomes white immediately; after a few seconds of immersion the plate is withdrawn and proceeded with as usual.

It is absolutely necessary that acetic acid be added to the nitrate bath, as it removes the excess of oxide of copper; at the same time it is well to diminish the quantity as much as possible. To an ordinary nitrate bath employed for collodion add one per cent. of acetic acid, and if, after developement, the proof is blackened, add another one per cent. of acid. If, however, there be too much acid, the rapidity of the process is diminished; if too little, the proofs are blackened.

An ordinary nitrate of silver bath will serve with the addition of a very small quantity of acetic acid—say, one-half per cent., provided the glass plate be allowed to remain immersed in it for two or three minutes, lifting it up from time to time; or the plate may first be immersed in water, acidulated with acetic acid, withdrawing it quickly, and when it has drained, plunging it into a neutral nitrate of silver bath. The time of exposure will be increased or diminished tenfold, according as the nitrate bath is properly adjusted which experience alone can determine.

To ensure success there is one point to be carefully determined—namely, When should the plate, coated with the iodised cellulose, be plunged into the nitrate bath, and how shall its action be regulated?

If at the expiration of half-a-minute after the plate is coated it be examined, it will be found that the upper part of the plate from which the liquid has drained has become opaline, while the lower part, still moister, remains transparent. If put into the nitrate bath in this state one portion will become whiter than the other, and, consequently, the action of the light upon it will be unequal. Therefore, before plunging the coated plate into the nitrate bath, it is necessary to wait until it has a uniform appearance, and to hasten it, the plate may be agitated for a few moments in the air; but if it be allowed to become dry its sensitiveness will be diminished.

Further experience may render this process still more certain: it is much simpler than that with collodion. Copper, ammonia, and cotton are cheap, and may be found anywhere, and it is not essential that these articles be strictly pure. This method promises success in the dry process.—*La Lumiere.*

Meetings of Societies.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting was held at Myddleton Hall on Wednesday evening, the 25th ultimo.

GEORGE SHADBOLT, Esq., Vice-President, in the Chair.

After the minutes of the previous meeting had been read and confirmed, the following gentlemen were elected members:—Messrs. M. Beck, H. Bumsted, F. Lyon, and D. Wilson.

Photographic negatives and prints were exhibited by—

Mr. SHADBOLT: Fothergill process.
„ D. W. HILL: (Views in the Isle of Wight) modified metagelatine process.
„ T. A. BARBER: (Views) oxymel process.
„ M. HANNAFORD: Fothergill plates, and an almost instantaneous stereoscopic picture by modification of the same process, by the aid of *citrate of silver*.
„ GAMHAM: Some excellent stereographs.
„ BINGHAM: Negatives, and prints taken from them, the plates prepared with gum-arabic and chloride of ammonium.
„ BARNETT: Stereographs by metagelatine and Fothergill processes.
„ Dr. RILEY: Plates by several variations of the collodio-albumen process.

Mr. HISLOP read a paper, *Remarks on the Preparation of Dry Plates*, see page 135, for which a vote of thanks was accorded to him.

The discussion on Dry Processes was then proceeded with.

Mr. HISLOP considered that plates prepared by the processes he had described required at least one-fourth less exposure than Fothergill's.

Mr. MOENS corroborated this statement, but was of opinion that gelatine plates were generally deficient in density.

Mr. BINGHAM found that by using a very diluted solution of gum-arabic the collodion film adhered firmly to the glass, and by the addition of chloride of ammonium, not only were the plates rendered more sensitive, but another advantage accrued—they developed very quickly.

The CHAIRMAN asked if any member had followed the suggestion thrown out in consequence of Dr. Riley's statement at the last meeting, of coagulating the albumen film (applied after washing away the free nitrate of silver) by means of sulphate of iron.

Mr. DUTTON had tried separately both sulphate of iron and nitrate of silver for that purpose. He prepared two collodionised plates in the usual way, sensitised and *thoroughly* washed them; while still wet, he albumenised with plain albumen, and again washed them. One he then immersed in the nitrate of silver bath, the other *in a solution of sulphate of iron;* gave the final washing to both plates and dried; exposed to same object an equal time, and so equal were the results that he cannot even now distinguish which plate was treated with iron and which with silver.

Mr. HANNAFORD had tried similar experiments, and found the plate coagulated with iron came out apparently more dense, but there was in truth equal intensity as regards printing qualities.

Mr. D. W. HILL found no advantage over the ordinary Fothergill process by redipping in the nitrate bath, after Dr. Riley's plan.

Dr. RILEY stated that he claimed nothing in point of sensitiveness or density, but for *uniformity;* for with care, and washing off all the free nitrate of silver, clean pictures were certain results. He exhibited some plates upon which he had experimented in the following manner:—

No. 1. Redipped in nitrate bath: result (according to the general opinion of those present about thirty members), very weak.
„ 2. Iron bath: result, no density.
„ 3. Hot water alone: result, more dense but too weak to print from satisfactorily.
„ 4. Thoroughly washed and dried: result, the most dense of the four.

Each exposed two minutes; developed in five minutes.

The CHAIRMAN stated there was one question yet undecided, and that was, had any one completely washed off *all* the free nitrate, without converting it into a chloride or analogous compound, leaving only the iodide of silver? Was it clearly ascertained whether *pure* iodide of silver is sensitive to light or not? He felt by no means sure that it was a settled question.

Mr. MOENS replied that he had failed to obtain a picture on a plate that had been *thoroughly* washed with *distilled* water, but by adding a little salt to the water used for washing the plates, they were rendered very sensitive.

Mr. D. W. HILL stated that Mr. Moens had suggested the addition of chloride in the washing water, now so strongly recommended, more than twelve months ago. He was desirous of knowing if any member had tried washing the plates with a solution of pyrogallic acid before exposure, as recommended by Mr. Barnes and Major Russell?

The CHAIRMAN had done so, and developed that very day, just before attending the meeting, a plate prepared seventeen days ago, together with one not so treated: the only difference he found was a slight stain at the corner of that one treated with pyrogalic acid, where it had drained; there was *no difference* in intensity.

Mr. HISLOP was of opinion that the albumen solution as usually employed for preparing plates by the Fothergill process was very much too strong, and this was the frequent cause of failure. Albumen diluted with thirty times its bulk of water he found produced much better results.

The CHAIRMAN, in answer to a question as to the use of ammonia in albumen solutions, replied that it was preservative in its character, and greatly added to the even flowing qualities of the albumen.

Mr. D. W. HILL had tried the addition of chloride of ammonium to metagelatine with great success, and exhibited a good negative, taken in ten seconds by that process.

The CHAIRMAN stated that as this was the last meeting before the vacation, the Committee would be glad to receive offers of the loan of negatives from which to print the presentation photographs.

Any gentlemen willing to do so were requested to communicate with the Committee on this subject, through the Hon. Secretary, Mr. John Barnett, 9, St. Peter's Terrace, Islington, N.

Mr. SPENCER offered the use of any negatives he had for that purpose.

After thanks to those who had taken part in the discussion for the valuable information elicited,

The Chairman wished success to all present in their photographic pursuits during the vacation, and hoped to see a large collection of pictures, as the result of their labours, at the next meeting of the Association, which is arranged for September 28th.

A vote of thanks was accorded to the Chairman, and the meeting separated.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

The seventeenth ordinary meeting of this Society was held on the 16th ultimo at the Golf Club-house, J. Glaisher, Esq., F.R.S., President, in the Chair.

After the usual business had been transacted, Messrs. Chatteris and J. Busk and Dr. Kidd were duly elected members of the Society.

The President proceeded to read a paper, which was a continuation of that commenced on the 21st of March, entitled "*The Application of Photography to Investigations in Terrestial Magnetism and Meteorology, as practised at the Royal Observatory, Greenwich.*"

Having described the apparatus by which the ray of light is concentrated upon the sensitive paper, enclosed in a glass cylinder, kept revolving at an uniform rate, by means of a chronometer, the rays of light from a lamp being reflected by a mirror (fixed by means of a stirrup upon the magnet, having free motion in a horizontal direction), through a lens arranged for the purpose on to the sensitive paper, the nature of the curves formed by the deflection of the magnet and the mode of calculating their value from a base line was described, the lecturer adverting to the "magnetic" storms which were on record, and showed that they are synchronous at various parts of the globe where observations are registered. He then proceeded to describe the following:—

Chemical Processes employed in the Photographic Operations for the Self-registration of the Variations in Position of Magnetical, and of the Variations of Readings in Meteorological, Instruments.

First Operation—Preliminary Preparation of the Paper—The chemical solutions used in this process are the following:—

1. Sixteen grains of iodide of potassium are dissolved in one ounce of distilled water.

2. Twenty-four grains of bromide of potassium are dissolved in one ounce of distilled water.

3. When the crystals are dissolved, the two solutions are mixed together, forming the iodising solution. The mixture will keep any length of time. Immediately before use, it is filtered through filtering paper.

A quantity of paper, sufficient for the consumption of some little time, is treated in the following manner, sheet after sheet:—

The sheet of paper is placed on a board, covered with oil-cloth, somewhat smaller on all sides than the paper, a condition necessary for preventing the iodising solution from running under the edges of the paper. The paper is usually pinned on the left side of the board. A sufficient quantity (about fifty minims for a sheet of paper fifteen inches long and nine and a-half inches broad) of the iodised solution is applied, by pouring it upon the paper in front of a glass rod, which is then moved to and fro till the whole surface is uniformly wetted by the solution.

The paper thus prepared is allowed to remain in a horizontal position for a few minutes, and is then hung up to dry in the air; when dry, it is placed in a drawer till used.

Second Operation—Rendering the Paper Sensitive to the Action of Light—A solution of nitrate of silver is prepared by dissolving fifty grains of crystallised nitrate of silver in one ounce of distilled water, adding, in hot weather, a few drops of acetic acid.

Then the following operation is performed in a room, illuminated by yellow light:—

The paper is pinned as before, upon a board somewhat smaller than itself, and (by means of a glass rod as before) its surface is wetted by fifty minims of the solution. It is allowed to remain a short time in a horizontal position, and if any part of the paper still shines from the presence of a part of the solution unabsorbed into its texture, the superfluous fluid is taken off by the application of blotting paper.

The paper, still damp, is immediately placed upon the interior glass cylinder, and is covered by the exterior glass cylinder, and is mounted upon the revolving apparatus, to receive the slot of light formed by the mirror, which is carried by the magnet.

Third Operation—Developement of the Photographic Trace—When the paper is removed from the cylinder, it is placed upon a board, and a saturated solution of gallic acid, to which a few drops of acetic nitrate of silver are added (in hot weather this solution is used at the temperature of the air, in cold weather it is heated to the temperature of seventy or eighty degrees), is spread over the paper by means of a glass rod, and this action is continued until the trace is fully developed. When the trace is well developed, the paper is placed in a vessel of water, and repeatedly washed with several successive supplies of water, a brush being passed lightly over both sides of the paper, to remove any crystalline deposit.

Fourth Operation—Fixing the Photographic Trace—The photograph is placed in a solution of hyposulphite of soda, made by dissolving four or five ounces of the hyposulphite in a pint of water; it is plunged completely in the liquid, and allowed to remain from one to four hours, until the yellow tint of the iodide is removed. After this the sheet is washed repeatedly with water, and afterwards placed within the folds of linen cloths till nearly dry. Finally, it is placed between sheets of blotting-paper, and a heated iron passed over it.

The paper concluded by details showing how—

From the original register, produced as above described, *negatives* are formed by means of the ordinary chloride plain paper process, in the pressure frame, the paper being impregnated with chloride of ammonium, and excited with ammonio-nitrate of silver, and after exposure being fixed as usual and ironed between sheets of blotting-paper. The negatives being thus obtained, any number of copies of the original register can be taken by a similar process for distribution and comparison.

At the conclusion of the paper Mr. Heisch remarked that the proportion of bromide to iodide of potassium was, as nearly as possible, two of bromide to one of iodide.

A vote of thanks was unanimously tendered to Mr. Glaisher for his able paper; and Messrs. Kent, Crossland, Skaife, and Kieser, having been proposed as candidates for future election, the meeting adjourned.

SECOND ANNUAL REPORT OF THE COUNCIL OF THE BLACKHEATH PHOTOGRAPHIC SOCIETY.

The lapse of another year brings round the Second Anniversary of the Blackheath Photographic Society, and the Council have the pleasure of presenting their Second Annual Report.

The Council heartily congratulate the Society upon its present prosperous condition.

During the past year, the Society's numbers have been recruited by the introduction of many of the influential residents in the neighbourhood, several practical photographers—and all zealous to promote the art of photography.

The Treasurer's Account is annexed, exhibiting a balance of £49, 11s. 2d. in favour of the Society.

The Soirée, which was held at the Mansion House, by the kind permission of the Rt. Hon. the Lord Mayor, on Friday, the 15th April, was eminently successful; and the works of Messrs. Glaisher, Heisch, Melhuish, Knill, Ledger, Smith, Spencer, Wire, and Wood, were such as to elevate the character of the Society from which they emanated. The following gentlemen contributed also materially as exhibitors to the success of the Exhibition, viz.—Messrs. Bedford, Bell, Bunning, Burfield and Rouch, Claudet, Cumming, Delamotte, Fenton, Frith, Horne and Thornthwaite, Jones, Knight, Ladd, London Stereoscopic Company, Murray and Heath, Malone, Negretti and Zambra, Ottewill, Paul Pretsch, Powell and Leland, Pillischer, Rayne, Reeve, Rosling, Ross, Salmon, Shadbolt, Smith and Beck, Thurston Thompson, Turner, White, Williams, E. G. Wood, and Herbert Watkins; to each of these gentlemen the Council beg to tender their warm acknowledgments.

Through the continued kindness of the Golf Club, the meetings of the Society have taken place during the past Session at the Golf Club House; the Council therefore offer their best thanks to the Officers of the Club for affording them a *locus standi*.

The following brief list of Papers read during the Session will show the energy and intellect which have been exercised on behalf of the Society by some of its leading members; and it is pleasing to record the fact, that the journals specially devoted to photography, and some of the local newspapers, have given a preference to many of the Society's papers in their publications, and by making them the subject of favourable criticism, have demonstrated their original and instructive character. The Council have to acknowledge, with many thanks, the great, nay, the special courtesy shown them by the press generally, and particularly by the editors of the local press, who have not unfrequently, during an unusual pressure of business, given insertion to, and notice of, the transactions of the Society.

The following is a list of Papers read during the Session:—

"On the Simultaneous Photography of various Coloured Objects." By Mr. Heisch.
"A Week with the Camera among the Hills of Kent." By Mr. Wire.
"On Nautical Photography," by Mr. Skaife, showing his "instantaneous method" of taking Photographs.
"On two main points in Photography." From Herr Paul Pretsch, read by the President; and, from the same source, a paper on Pretsch's "Photogalvanographic Process."

"On Metagelatine as a substance for mounting Photographs." By Mr. Heisch.
"On the Dry Collodion Process." By Mr. Heisch.
"On the application of Photography to investigations in Terrestrial Magnetism and Meteorology, as practised at the Royal Observatory, Greenwich." By Mr. Glaisher.

The Council regret that so few strictly scientific researches have this year to be reported, as from these only can fundamental improvements be expected. M. Nièpce de St. Victor continues his experiments upon the so-called storing up of light. Without absolutely ignoring his facts, a careful examination of his experiments, as reported by himself, convinces the Council that they by no means justify the theory he has raised on them. The fact, that the bodies supposed to contain the bottled light exercise their reducing action only through porous substances, such as paper, and have no action through glass or other non-porous substances, however transparent, while the reducing action of light passes most easily through transparent bodies, quite independently of their porosity, —coupled with the admission by M. Nièpce, that heat, vapour of water, and any thing which favours the passage of vapours through such substances as paper, materially assist, if indeed they be not essential to the supposed new action—render it more than doubtful if light have any thing to do with the matter. It is also worthy of remark, that none of those accustomed to scientific investigation, who have attempted to repeat his experiment, taking the most moderate precautions against self-deception, have ever succeeded; while Mr. Crookes has shown that at least one of his experiments is quite as successful with substances that have been kept rigorously in the dark. On the whole, the Council see no more reason for ascribing the effect produced by M. Nièpce to light, than they do for attributing anastatic printing to the same agency, because the nitric acid employed in that process penetrates the white parts of the paper, and attacks the zinc plate beneath them, while it does not attack those parts which are covered by the ink. In another direction, however, M. Nièpce's experiments seem to have led to more satisfactory results. He has added to the number of substances which receive an impression from light capable of after-development, and the Uranium Printing Process, founded on these experiments, promises to become of some importance. M. Chevreul, in an appendix to M. Nièpce's last paper, points out the necessity of distinguishing between such substances as are acted on by light alone and those which are only affected when oxygen is present; and gives a list of those substances on which light acts "in vacuo," of those on which it only acts in the presence of air, or of oxygen, or of those bodies in conjunction with moisture.

The Council must also bring under the notice of the Society Mr. Pouncy's Carbon Printing Process; for though they can by no means agree with him in his assertion that his prints are quite equal to silver ones, the immense strides he has made, in a comparatively short time, render his process one of great promise. At the same time, the Council cannot but remark that the conclusion that the prints must be as permanent as those made with printer's ink, because in both carbon is the colouring matter employed, has been much too hastily arrived at, as it has yet to be proved that the glue and bichromate of potash employed as a vehicle is as unalterable as the oil, resin, &c., which enter into the composition of printer's ink.

The discovery of Mr. J. H. Young, that the invisible image on a collodio-albumen plate can be developed, after the removal of the iodide of silver, by hyposulphite of soda, or cyanide of potassium, is too important to be passed over without notice, showing, as it does, that the change produced in the iodide of silver by light is even greater than has hitherto been thought. At present, it does not appear that he has produced any but transparent positives, printed from negatives by superposition; so it remains to be seen if the comparatively feeble light of the camera is capable of producing the same effect.

The Council would take the opportunity of reminding Members of the forms for the registration of observations with which they were last year furnished, none of which appear, up to the present time, to have been filled up. They would press upon Members the necessity for a little exertion on this point, as it is only by a comparison of a number of observations, made in different places, and under various other considerations, that any good results can be hoped for. With a view to facilitate these observations, Mr. Heisch has prepared shorter forms, embodying only the most important points, and those which can most easily be attended to in the field.

The new forms of lenses are still exciting much discussion. The Members have had some opportunity of judging of the results obtained with them at the late exhibition at Suffolk Street. The pictures by Mr. Bedford were mostly taken with a Grubb lens, those by the late Mr. Howlett with a Ross Petzval.

The Society, since the publication of the last Report, have to regret the loss of several Members, from various causes, chiefly through removal from the neighbourhood, among whom should be especially noticed the name of G. Busk, Esq., F.R.S. The Council record the secession of such with regret. While acknowledging with thankfulness the labours of those Members, who in the midst of important avocations have kindly devoted their time to the production of papers for the intellectual gratification of the Society, the Council have to urge upon other Members the necessity of contributing somewhat to its intellectual maintenance, recording their opinion that a failure in this particular presses somewhat unfairly upon those gentlemen who have already exerted themselves so much in that direction. In conclusion, the Council point with satisfaction to the position the Society has obtained in public estimation, and venture to add that such combinations cannot fail to exert a beneficial influence upon the community at large, fostering, as they do, two important principles, viz., the extension of scientific information and original research, and the bringing together, for that result, those who are desirous of cultivating knowledge.

Exhibition.

GLASGOW PHOTOGRAPHIC SOCIETY.

[FROM OUR OWN CORRESPONDENT.]

ALTHOUGH this Society's exhibition is now closed, the following analyses of the subjects and processes represented may be interesting:—

SUBJECTS.

Portraits, numbered	259
Studies and compositions from life	62
Landscapes: Views from nature and architectutal subjects	441
Stereographs: Chiefly views from nature and architectural subjects	125
Astronomical: The moon in various phases	4
Microscopic enlargements of minute objects	17
Microscopic reductions of engravings, &c.	20
Machinery	6
Copies of engravings	40
Copies of paintings	17
Sculpture	8
	999

PROCESSES.

Collodion: Of this there were pictures to the number of	642
Honied collodion	12
Collodio-albumen	71
Hill Norris's process	8
Fothergill's process	1
Mr. Kibble's experimental dry process	10
Collodion positives on glass	57
Collodion on leather	1
Albumen	93
Talbotype	16
Waxed-paper	56
Daguerreotype	1
Not ascertained	31
	999

I may add that the collection was admirable, and contained fine pictures by Fenton, Lyndon Smith, Robinson, Rejlander, B. B. Turner, and most other well-known artists. There was a marked progress in artistic feeling to be seen throughout the collection as compared with the last exhibition held in Glasgow. More attention is evidently being paid to pose and expression in portraiture; to the selection of the best point of view in landscape and architectural subjects; and in all, to an advantageous disposition of light and shade. Then we had very fair attempts at art itself, in such efforts as the studies and compositions of Robinson, Rejlander, and Fenton.

Judging from this exhibition, collodion, and next to that, honied collodion, seem to produce the most desirable effects in the way of securing sharpness and detail, along with softness and half-tone. Fothergill's and Norris's processes were insufficiently represented. Taupenot's process was generally harsh and too snowy in the lights, but there were some beautiful exceptions to this rule. B. B. Turner's pictures showed well what could be done by Talbotype. Excellent results were exhibited in views from waxed-paper negatives, by the Rev. Mr. Raven and others. This process seems to be admirably capable of securing distance. With these brief remarks I must close. OBSERVER.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER III.

UPON COLOUR.

ALL colours have their origin in the decomposition of light, which is, in its perfect or entire state, colourless. Newton first proved the compound nature of the solar beam, and traced all the varied hues and colours of nature to the seven rays of the prismatic spec-

trum; but of these only three are now generally admitted to be really primary, viz.—red, blue and yellow. As pigments, artists always considered these three colours primary, because, by no combination of pigments could they be produced, but by uniting the three named, or some of them, in different proportions, all other colours could be obtained.

Black and white represent, in nature, the absence and the presence of light; and to colours in nature, or as they exist as pigments, black and white bear much the same relationship; darkness (the absence of light) is in the same proportion the absence of colour; so black, its representative, degrades pigments from their native purity and brilliancy. On the other hand, white is in pigments, as in nature, the representative of perfect light, although the brilliancy of a white pigment cannot be of course compared to that of white light—to force the effect of white by contrast is therefore a point of some importance, as in reference to light and shade I pointed out in the last chapter.

"Colours," Opie says, "are the sunshine of art that clothes poverty in smiles, and renders the prospect of barrenness itself agreeable, while it brightens the interest and doubles the charm of beauty." In appealing to the mind, no assistance is more powerful than colour; a picture in light and shade may be effective and suggestive, but it grows tame and poor when contrasted with one of the same subject, executed with equal skill, in colour.

What speaks so eloquently of health as the hue of ruddy freshness glowing through the clear firm flesh? or of disease, as the sickly pallid tint which overspreads the emaciated form? The wild storm is most felt through the gloomy hues of sky and landscape; and what can express the misty romance of dying day so well as the purple shadows, and the clouds of gold and crimson which glow in the horizon, beneath the darkening violet of the solemn sky above our heads? Colour is quite as important in portraiture, and more especially photographic portraiture: the healthy red, the pallid, the sallow, the beautiful pink and white, or the sickly complexions, are as vital to *truthful* resemblance as form itself; and the colours of the eyes and hair are of no less importance. Here photography does very frequently fail: the red colour upon the cheek it represents by *a shadow;* the pale blue eye, melting in liquid light and full of tender beauty, is very frequently in the photograph misty, indefinite, expressionless, and *barely visible,* and the rich auburn hair *black.* I do not say, with many, that this is *necessarily* the case: I do not believe it is; but it is *very* common to see such defects, and will be so, I fear, until the principles I urged upon the reader's notice, in the preceding chapter, be generally studied and carefully applied.

PRIMARY AND COMPOUND COLOURS.

Of the three primary colours (red, yellow and blue), yellow is the most nearly allied to light (or white), and blue to darkness (or black); by mixture, we obtain from these colours orange, green, and purple—the first by the mixture of red and yellow; the second by yellow and blue; and the third by blue and red. From these we derive a third set of compounds, viz.—citrine, a mixture of green and orange; russet, of orange and purple; and olive, of green and purple.

To understand the full value of colours and their hues, we must look upon them as representative of certain qualities, viz.—warmth and coldness, light and shade; the power of harmonising and contrasting; of expressing sentiment, local character, breadth and relief; of advancing and retiring; in short, of powers which (apart from mere local characteristics) it is impossible to over estimate in their relation to the higher order of artistic effects.

(To be continued.)

Letters to a Young Photographer.

No. XI.

MY DEAR EUSEBIUS,

So you cannot develope your picture? The developing mixture I prescribed will not flow over the plate, no matter how you coax it? Well, there is a remedy for most human ills, except impecuniosity; and, perhaps, I can help you to a solution of your developing difficulty. It is supposed that the reason why the developing solution will not flow over the collodion consists in the presence of the ether in the collodion: this may be got rid off, to a great extent, by moving the plate up and down several times while in the nitrate bath; but if you add about one ounce of alcohol to the developing formula I gave in my last, I have no doubt, when you next try it, your developer will flow as freely as you can wish. I have learnt to do without the alcohol myself, but it was only after the expenditure of much patience, more, perhaps, than in your present stage of initiation you will care to bestow. It is quite essential to the obtaining of a good negative that the developer should spread promptly, for, if it remains upon one part of the plate and not upon the other, the process of development will go on unequally, and no subsequent care or pains will make it right. The skill required will come to you by practice, aided by a determination to succeed: so be not discouraged by early difficulties.

When you are satisfied that the developing is effected, wash off the solution with a gentle stream of water, poured from a pint jug: your next proceeding is to fix the image, which consists in removing all the iodide of silver from the collodion, by means of suitable solvents: these are—hyposulphite of soda and cyanide of potassium.

There is not much choice between these two solvents; both have their objections, and they should not be used in the operating room, on account of the inconvenience to which they are apt to give rise. I have a great horror of hypo, for it gets upon your hands, and if you touch anything while they are soiled with it, no end of mischief occurs: for this reason I give the preference to cyanide of potassium. But I shall describe both to you, and then you will be able to choose for yourself. Take a pint bottle and fill it nearly with water, and make a saturated solution of hypo by putting into the bottle as many crystals of this salt as will dissolve. You can pour from the bottle as much of this solution on to the plate as will cover it. The yellow iodide of silver will be seen to gradually disappear, the plate becoming transparent when it is all dissolved. When this has taken place, the plate must be washed for five minutes under a gentle stream of water, to remove all the hypo. A prolonged washing with hypo is very necessary, for if any be allowed to remain in the collodion it crystallises when the film becomes dry, and the picture is destroyed. If the plate is thoroughly washed from all traces of the developer, the image will appear positive as well as negative; but if the washing be imperfectly performed, and any traces of acid are retained by the collodion, when the hypo is poured upon it, it is decomposed, and a quantity of sulphide of silver is formed, which prevents the picture from assuming a positive aspect. This effect never follows the use of cyanide of potassium, which, containing no sulphur, always yields positive pictures when they are held over a black ground. I think all the advantages which may be attributed to the use of hypo are more than counterbalanced by the inconveniences arising from its use.

To fix with cyanide of potassium dissolve one ounce of this salt (if pure) in five pints of water. Pour a sufficient quantity of this solution upon the plate to cover it: its action is very rapid, and must be carefully washed. As soon as all the iodide has disappeared, wash the plate under a gentle stream of water, and set it up to drain.

A decomposition of the cyanide takes place during the developing, and vapours of prussic acid are liberated, which are injurious to inhale. You will, therefore, exercise due caution in making use of this dangerous fixing agent.

When the plate is carefully washed free from the developing agent, lean it against the wall, resting upon a slip of wood, to drain and dry. The time this operation requires will, of course, depend upon the weather; but if you are in a hurry, you can hold it before a clear fire. When quite dry, the plate is ready for varnishing. The best varnish for collodion negatives is that made of white lac. Take

Alcohol	10 ounces.
White lac	1 ounce.
Essence of lavender	2 ounces.

The lac will dissolve in a few hours; but previously to its being put into the alcohol it must be broken into small pieces, and carefully dried in an oven or in the sun. In the process of bleaching yellow lac water becomes enclosed within cells formed in the body of the resin, and, entering into the varnish, will cause the appearance upon the plate termed *blooming.*

You will make the plate quite warm (not hot) before the fire, and have the varnish warmed also; pour it over the plate in the same manner as you do collodion, and when it is quite covered return the surplus to the bottle, and set the plate to dry, out of the dust.

The quality of a varnish must necessarily depend upon the resin of which it is composed, and also upon the solvent employed to dissolve it. As to the resin, to be fit for photographic purposes, it must be hard, colourless, and transparent; a resin like mastic or dammar is too soft and brittle, and so is any resin that can be easily crushed under the finger-nail. If you require to print many posi-

tives from a negative, it is a matter of very great importance that the varnish with which it is covered be tenacious. A very little friction will rub off in a state of fine powder such resins as mastic. After many experiments, I have found no varnish so tough and adherent as lac; it never becomes *tacky*, even when the negative is printed in the heat of a summer's sun. A very good varnish may be made of gum benzoin, one ounce of which, dissolved in ten ounces of alcohol, and filtered, gives a very solid, clear, tenacious varnish, which is the next best to lac. Beware of the chloroform-amber varnish: I have lost several valuable negatives by its use. The amber softens in the heat of the sun, and the negative adheres to the positive paper.

The solvent of a resin should be a completely volatile substance; alcohol, ether, chloroform, and camphine are of this class. Common turpentine, a very good solvent for many resins, contains itself a portion of resin, which frequently gives a tackiness to varnishes; it must never be thought of for photographic purposes. Camphine, which is highly rectified turpentine, should always be preferred.

I have spoken of varnishes under the supposition that you will require to print a good many positives from your negatives. If you only require to print one or two there is no need to varnish your negative at all if you handle it very delicately. You may use gum-arabic as a varnish, making a solution of one ounce of gum in ten ounces of water, and straining through fine muslin, or what is better, tying up the gum in a muslin bag, and suspending it in a bottle or jar of water. Albumen makes a very good varnish; it is very tough, and keeps the "darks" in all their pristine opacity. I do not know but what I prefer albumen to any other thing for a varnish, now I come to think of it, but why I have not made greater use of it I cannot tell. I shall take it into favour again immediately. You will cover the collodion plate with the albumen while it is still wet, and when it is quite dry immerse the plate in the nitrate of silver bath (for exciting), in order to coagulate the albumen. Wash the plate carefully, and then pass it into a weak solution of hypo to remove any traces of nitrate of silver that may remain; then wash the plate again and dry.

ERRATUM in last letter, page 128, in formula for developing with sulphate of iron—

For "solution of sulphate of iron *ten* ounces" read ONE ounce.

Photographic Glossary.

Mercury; Quicksilver—A metal remarkable for existing in a liquid state at ordinary temperatures. It is of a silvery aspect and without taste or smell. It boils at 660° and is converted into a dense colourless vapour. It combines with oxygen, chlorine, bromine, iodine, sulphur, and most of the metals, forming *amalgams*. Mercury is the developing agent in the daguerreotype process.

Metagelatine—A name given to gelatine which has lost its property of solidifying, or becoming gelatinous: a change effected by boiling gelatine with a diluted acid. It is employed in photography to preserve collodion in a moist state in the same manner as honey.

Methylated Spirit—A mixture of 90 per cent of spirits of wine, sp. gr. 0.830, with 10 per cent of purified wood-spirit. This is an economical substitute for alcohol in the preparation of ether, chloroform, varnishes, &c.

Mica—A transparent mineral which occurs in laminated plates, which are hard and flexible, and may be split into thin flakes. It is a frequent substitute for glass, and is employed in photography for protecting pictures in lockets, &c. It is a silicate of lime combined with silicate of alumina.

Micro-photography—Applications of the microscope to the art of photography, one of which consists in taking pictures of objects on so small a scale as to require a powerful magnifier or microscope for viewing them. Although mostly used as a toy, this kind of ingenuity could be turned to useful account in the time of war, as despatches might be rendered on so small a scale as to ensure perfect secresy even if the bearer were arrested. The other branch of micro-photography, or more properly photo-micrography is of high scientific interest and utility = consists in producing highly magnified images of minute objects, as they appear under the high powers of a microscope.

Milk—A white liquid secreted by the mammallary glands of the females of various animals. It is a very complex substance, consisting of a multitude of fatty globules, which upon repose rise to the surface and form cream, and of another substance termed *casein* (cheese), which may be separated from milk by the addition of acid, the other portion being *serum* or whey, which consists of a solution of sugar of milk and albuminous matters. The serum is employed in photography as a solvent of the iodides; the albuminous substances it contains together with the sugar of milk act as an excellent sizing material.

Muriatic Acid—A name given to Hydrochloric acid, which is also sometimes called spirits of salt.

Nickel—A white metal, much employed for making alloys with copper, which it renders white also. The iodide and bromide of nickel have been used with satisfactory results for iodising collodion.

Negative—Photographic pictures;—so called in consequence of the lights and shadows and position of objects being the reverse of what they appear in nature. The images of objects received in the camera are always negative. This term has been greatly objected to by scientific writers, who propose to substitute for it the term *inverse*.

Nitrates—Compounds formed by the union of nitric acid with bases. The most important nitrate in photography is the nitrate of silver.

New Books.

Love Letters of Eminent Persons. By CHARLES MARTEL. London: W. Lay, King William Street.

WE feel convinced that Mr. Martel is a photographer; the selection of his publisher declares it, and though he speaks personally but in six short pages of introductory matter, the same idea obtrudes itself upon the reader. If not, why does he send us his book for review, for we cannot find anything about photography in it? What an immense accession of interest would have been gained had it been possible to have published with the letters, photographs of the writers. We commend this idea to him; and although it is now impossible to photograph the originals, authentic portraits of many, if not most of them, are to be found, and photographic copies of these would materially enhance the value of the text.

Foreign Correspondence.

Paris, May 24, 1859.

PHOTOGRAPHIC activity has suddenly taken a new phase; its impulses are all for Italy, and happy is the artist whose *atelier* contains a good stock of negatives from Sardinia, and other Italian states now the centre of interest and of strife. If I stroll along the Boulevards, I see no photographs in the *magasins*, but views of Turin or Genoa, or Milan, or Venice; or portraits of Victor Emmanuel and Count Cavour. War enthusiasm is raised to such a pitch, it is really quite infectious. I caught myself this morning asking for six ounces of gunpowder, when I really wanted collodion. I have some compunctions in using gun-cotton, when I think how useful it might be to those who are fighting for their liberties; I hesitate to make any more of it, because the nitrate of potash may be required for making gunpowder; I look at my bright brass objective, and wish it were a rifled cannon. If I whistle, it is always the new tune, *Viva la Liberta*. When I meet a chum in the streets the only salutation I receive is, "When are you off to the war?" Nothing but my deep and sincere devotion to the interests of *The Photographic Journal* keeps me here. The army is well equipped with its staff of photographers. I could have been one among them, but here I remain to chronicle the silent but onward march of photography. I hope you will at least give me credit for self-denial; for, if the war goes on, I shall soon be left here alone, the last of the peripatetic photographers.

Photographic engraving has made a new stage of progress under the hands of M. Bershtold, who has sought to remove a radical defect inherent in the methods of engraving by light hitherto employed, which is the want of *grain* in the plate. M. Talbot sought to remove this defect by the use of powdered rosin, but the grain so produced being of equal texture throughout the surface of the plate, produces a disagreeable flatness. M. Bershtold produces a kind of *hatching*, which is distributed just where it is wanted in the desired quantity. His plan of operating is to prepare a glass plate, by covering it with an opaque varnish: by ruling the entire sur-

face with a fine point, an infinite number of lines very close to each other are produced. When the metal plate endued with the sensitive preparation is submitted to the action of light, and the image impressed upon it, before it is washed, this ruled glass is placed upon it, successively, in various directions, horizontal, vertical, and diagonal, and exposed to the light. Upon those parts of the sensitive compound which have received the action of light, and become insoluble, no new effect is produced; but in those that are not, an infinite number of cross hatchings is produced by the light passing through the lines in the ruled glass. Although the experiments are at present but very imperfect, the results are exceedingly encouraging, and will doubtless lead to great improvement in future operations. M. Niépce de Saint Victor has announced a new process for obtaining black proofs, without the employment of the salts of silver or of gold. He takes one of those red pictures described in my letter of April 23rd (page 114), and turns it into a black one, by immersing it in a solution of per-chloride of iron, of the strength of five per one hundred, to which one per one hundred of pure hydrochloric acid has been added. In the course of a few seconds the proof becomes of a greenish black; it is then removed from the iron solution and rinsed in pure water; it then acquires a fine black tone, which it retains when dried. It must not be left too long in the water, especially if the water is a little alkaline, else the proof will take a rusty black tone: proofs obtained by this method are very beautiful, the whites very pure, and the half-tones well graduated. MM. Davanne and Joüet have presented some observations upon obtaining pure whites in direct positives on collodion. They propose nothing new, but substitute a purely chemical formula for the empirical ones in general use. They say that, in order to obtain pure whites, it is necessary that the particles of silver deposited, forming the image, be as pure as possible. This purity will depend upon the quality of the developer. Their improvement consists in adding to the iron developing agent sulphuric acid, in a quantity equal to one-fourth of the weight of the sulphate of protoxide of iron employed. A soluble sulphate of iron is produced which, unlike the sulphate of the peroxide formed in the usual method, is washed away from the collodion, instead of being precipitated with the silver, and so forming a discoloured image.

The report on the prize offered by the Duke de Luynes has been presented by M. Perier. It is a very lengthy document. I can only give you the results. The prize is not awarded to a single individual, but is apportioned as follows, in gold and silver medals of the value indicated:—

M. John Pouncy	400 francs	(silver).
MM. Garnier and Salmon	400 ,,	,,
MM. Davanne and Girard	600 ,,	(gold).
M. Poitevin	600 ,,	,,

It will be remembered that the prize was offered for the best method of securing the permanent positive impressions on paper, under the following conditions:—

Verifying, with respect to accidental fading, of a certain number of proofs.

Admission in theory, under certain conditions, of the possibility of fading, of proofs of any kind.

Greater utility of researches tending to render every picture, if not permanent, at least as durable as the products of printing, engraving, and lithography, have hitherto proved.

It was generally conceded at the time this prize was offered, that it was to carbon we should look for the desired permanent printing agent; and it will be seen that two out of the four medals have been given for processes of carbon printing. Much of the discredit thrown upon processes for printing with salts of silver has arisen from the careless manner in which the proofs have been treated, both in toning and in washing, chiefly by persons ignorant of the nicety and care required by chemical operations: such artists have supplied the large crop of faded photographs which abound on every side. There are abundance of good proofs extant, taken many years ago, which, carefully treated in all the various manipulations to which they have been submitted, exhibit every promise of continued permanency, having during the time they have already existed, undergone no visible alteration.

The report first specifies those candidates who put themselves out of court by not complying with the conditions imposed upon competitors for the prize. This left four candidates, whose several claims to the prize were so nicely balanced, that is was divided between them.

M. Pouncy's carbon-printing process is identical in principle with M.M. Garnier and Salmon's, and nearly identical in the details of execution with that of M. Poitevin. The peculiar modification of M.M. Garnier and Salmon's process, consists in their applying the carbon in powder after exposure to light. They commence by dissolving 30 drachms of loaf sugar in an equal weight of water, then adding 7½ drachms of neutral bichromate of ammonium dissolved in a glass mortar. Then add to this compound 10 drachms of frothed albumen, to which a few crystals of bichromate has been added, mix these ingredients thoroughly together, and strain through fine muslin. Fasten a sheet of paper to a small board, and spread the mixture upon it with a large round hog's-hair tool, taking no more of the liquid than is just sufficient to cover the paper equally, thus avoiding streakiness. It is next dried before the fire, and then exposed in the printing-frame under a positive. The exposure required in a cloudy day will be about fifteen minutes. Upon removing the paper from the frame the image will appear of a yellow brown colour, deeper than that of the bichromate; it is then warmed before the fire, heat appearing to continue the action of the light, by which the intensity of the picture may be in some measure regulated. The paper being again fixed upon a board, spread by means of a flexible brush a coating of fine ivory-black; this pigment is preferable to lamp-black. The operation is finished by spreading the black evenly by a tuft of cotton; the paper, removed from the board, is held before the fire for a few seconds, and then plunged carefully, picture uppermost, into clean water, in which it must be moved about carefully, and then left to repose. In about a quarter of an hour it may be taken out very cautiously and hung up by two corners to dry. The whites will appear rather tarnished. Lastly, the proof is put into a bath containing 5 parts of a concentrated solution of sulphurous acid to 100 parts of water, exercising the same care in this bath as in the preceding. The whites will now appear nearly pure, some particles of carbon still adhere to them, and the principal difficulty to be overcome in this process is to obtain pure whites; at present the proofs are imperfect in the half tones, the distances and other delicate parts in a landscape are imperfectly expressed, often undecided and ill defined, and the shadows want depth and homogeneity. The manipulation of this process is not so simple as in that of M. Pouncy, but much less time of exposure is required, while the results are nearly equal in both methods. M. Pouncy's method has the advantage of permitting the employment of a negative instead of a positive, as required in Messrs. Garnier and Salmon's process.

The committee of inquiry consider that M. Poitevin is the real originator of the processes based upon the employment of bichromates, he having announced his method in August, 1855.

Messrs. Davanne and Girard received a prize for their valuable researches upon the philosophy of positive printing, which, as they have been duly recorded in the pages of *The Photographic Journal*, I need not recapitulate.

J. P.

New York, May 11, 1859.

On the evening of the 9th instant the Photographical Society had a meeting, for which many *invitations* were issued — if not to followers of the art, to its patrons—at least, so far as having each one some time or another sat for a map of his face. The *pseudo-claimant* of the process of taking daguerreotype portraits was in the chair, he being the *de facto* president of the Society; but having been a Professor in an University, he has been placed over the head of the real producer of the first portrait from life ever taken by the camera, who is in a very subordinate situation in the Society. *Brass* is a very valuable commodity in America as well as elsewhere.

Mr. Seely read two papers — one on *Dry Collodion*, in which he clearly set forth the importance of "Seely's pyroxyline," dissolved in his "Photographic ether" and the "photographic alcohol," all of which articles are "well known to readers of *my* journal." The second paper was on *Sensitising Albumen Paper*.

A young gentleman described a new method of darkening collodion negatives, by using proto-chloride of palladium.

Mr. Seely exhibited the *original and new* process of detaching the collodion film from the glass. Several detached films were handed round. After this, followed a discussion on the sunflower, and on love apples; of the last of which, Mr. Snelling, the ex-editor, declared he was very fond. Mr. Seely also took part in this question.

A proposition was made to the effect that some one rich enough should offer a premium for the best formula for making dry collodion, which should be more sensitive and much more pleasant to work than *wet* collodion. This premium to be called the Society's prize, and to be awarded by Mr. Seely.

Copies of the "*constitution*" of the Society were given to all present who would receive one, and the meeting then adjourned, to meet again on the second Monday in June.

A change is gradually taking place in the *personnel* of the art in the public establishments. In some few of them young ladies are the printers; and it must be said in their favour, that the prints produced by them are not surpassed by any, even if equalled, either in clearness of tint or gradation of tone. Female hands and tact appear better adapted to the delicacy of the necessary manipulations on the tender paper than those of the other sex, none of whom are fond of dabbling in water — consequently, are apt to slight the use of it.*

We hear no more of the Cutting injunctions, but we have an advertisement going the rounds, cautioning every one to avoid infringing on a patent of *Whipple's*,† "for taking pictures on glass plates," of an earlier date than Cutting's; thus cutting even Cutting out, as Cutting can only use his patent on cut-glass plates.

Photographic weather is still, for out-door operations, as great a desideratum as when I last wrote to you. Rain, high winds, dust, rain, high winds, dust, has been the rotation for a long time back, and the torrents falling at this moment would almost induce the idea of another deluge being at hand. ARGUS.

ENLARGING BY A PATENT (!) PROCESS.

To the Editor.

Sir,—The enclosed paragraph was cut from to-day's impression of one of our local papers:—

"Improvements in Photography.—Messrs. ——— and ———, who have hitherto done so much in bringing photographic portraiture to a high excellence in Liverpool, seem determined not to be outdone in the race for public favour. By the purchase and adoption of an American patent, just introduced to this country, they are enabled from the smallest negative to reproduce portraits of any dimensions up to life-size, and this without, in the least degree, lessening the sharpness of outline or the clearness of detail that belong to their smaller pictures. We have before us at present one of the first portraits enlarged by the new process, and it is, indeed, a marvel in photography — preserving the fidelity of the miniature with the artistic excellence of a large mezzotint engraving."—*Liverpool Daily Post.*

I should much like to know if the so-called American patent is one of the "*American patents*" that we have been so much favoured with for the last year or two, obtained for new (!) inventions of processes, &c., which have been published here or elsewhere—in some cases even years before. Any one who has had the smallest experience in photographic manipulation ought to know how to produce a picture any size from a negative, no matter how small, without losing any of the detail.

Although a sincere admirer and ardent practiser of photography, I do not follow it for a living; but if I did, I am afraid I should be very much inclined to be the first to infringe the "*American patent*" right.—I am yours, &c. CRAM.

Liverpool, May 25, 1859.

[As Mr. Squeers said to Nicholas Nickleby, "Dotheboys Hall is not *exactly* a *hall*," but there is no act of parliament against a man's calling his house an *island* if he please;" so photographers can, if they please, vilify their own productions, by dubbing them *patent*.—Ed.]

TONING AND FIXING.

To the Editor.

Sir,—As "reform your toning baths" seems to be the order of the day, I have made one according to the formula of M. Bayard, given in your January number, on page 11. I find that the *fixing* bath is only composed of five *drachms* of hypo to thirty-three ounces of water; while, on page 4 of the same number, Hardwich's fixing bath is *six ounces* of hypo to one pint of water. I should, therefore, be greatly obliged if, in your next number, you would say if Bayard's fixing bath is given correctly? If it is, do you think it is sufficiently strong to be used for any length of time?—I am, yours, &c. F. B. E.

May 18, 1859.

[The fixing baths are both given correctly; but that of M. Bayard is not intended to be used for any length of time, but a fresh bath made every day, or as often as the operator may be printing. We prefer Mr. Hardwich's and Mr. F. M. Lyte's formulæ to M. Bayard's. Mr. Lyte's, especially, is pleasant to work with.—Ed.]

* We doubt not the advantage of female manipulation, but cannot assent to the importation of *mild hydrophobia* on the part of our own countrymen.—Ed.

† Whipple's albumen process is so patented.

DIAPHRAGMS BETWEEN LENSES.

To the Editor.

Sir,—I have been lately using a portrait lens, stopped down with a small diaphragm, *between* the lenses, for views; but nearly all my negatives are spoiled by a circle of light in the centre of the picture corresponding to the size of the diaphragm used. I have tried various means to obviate the difficulty, but have as yet failed.

Will you, through the medium of your valuable journal, explain the *cause* and *remedy* for this evil?—I am, yours, &c.

ONE IN A FIX.

[The cause is, probably, a partial cutting off of the oblique rays by some part of the fittings, probably by too long or too contracted a sun-shade in front of your lens: the remedy is obvious, if our conjecture be correct. The diaphragm is also, probably, not in the right place: it should be nearer to the front than the back lens, say two-fifths of the distance between the lenses from the front combination. See also reply to Lux.—Ed.]

MANIPULATORY DETAILS.

To the Editor.

Sir,—I have seen some photographic prints mounted on card-board, with a beautiful hard smooth surface. This effect was accomplished by means of a *press*.

Would you be kind enough to inform me, through your valuable journal,

1st. What kind of press is best adapted for the purpose, and where are they to be purchased?

2nd. The best method of masking negative portraits, and printing in plain backgrounds?

3rd. The paper best suited for portraits to be coloured or tinted in sepia, &c.?

4th. The best mode of varnishing stereoscopic prints, &c.?—I am, yours, &c. HELANDRUST,

Sunderland, May 18, 1859. An Old Subscriber.

[1. The operation you mean is what the French term *cylindering*, and is performed by passing the proof between steel cylinders, similar to a copper-plate printing press, which will itself answer the purpose, the proofs being placed between pieces of highly-glazed milled-board.

Mr. Francis, of Great Russell Street, London, sells a very efficient substitute for the purpose, consisting of a cylinder of wood, turned by a handle; a thick piece of plate glass being forced against the cylinder, by means of a screw, acts as a burnisher; the proof, either mounted or unmounted, is placed on the glass, face downwards, and drawn between it and the cylinder by turning the handle.

2. We presume, by this question, that you do not mean "*vignetting*," but printing clean backgrounds from negatives deficient in this respect. It is sometimes effected by placing a sheet of sensitive paper under the negative in the pressure frame, and exposing until the *outline* is distinct. The paper is then removed, and the *figure* neatly cut out; the remainder of the paper is then exposed to the light to blacken, and is to be gummed or glued *on to the negative*, leaving the figure bare. On printing from it, the background will, of course, be perfectly white.

3. We have a strong bias in favour of Hollingworth's paper for this purpose. Good *thick* Saxony paper also answers well.

4. Paper prints to be *varnished* must first have a good coating of *size*. They may then be *French polished*, which gives the *best* possible face — or they may be varnished with what is known as white paper-varnish, sold at the varnish makers. We believe, also, that pure white wax and turpentine is sometimes employed for this purpose.—Ed.]

MANIPULATION, &c.

To the Editor.

Sir,—1. What do you consider the best method of developing the collodio-albumen plates; that is to say a number of small ones at one time? also the nature and strength of the developer?

2. How to *make sure* that pictures (positives) fixed with hypo on glass will not fade.

3. Cannot albumenised plates, as suggested by Mr. MacNab, be used with advantage in the collodio-albumen process? at the same time, is not the iron liable to injure the bath, as I do not think it possible to wash sufficiently to remove every particle?

An answer in your next would add greatly to the obligation you have so often conferred upon, yours, &c., QUERIST.

[1. By putting them in glass dishes face downwards, resting on glass corners. Develope with saturated solution of gallic acid, to which a few drops of solution of nitrate of silver have been added. Or use pneumatic plate holders, and level a board to stand them on, and develope with pyrogallic acid one grain, distilled water one ounce, citric acid quarter of a grain. Mix with an equal bulk of honey syrup, and just before use add a drop or two of solution of nitrate of silver, pour on and off several times, and then drain for a few seconds; a sufficient quantity of developer will remain on the plate to develope the picture slowly.

2. Wash well, drain, and let the last drop *fall on the tongue*, if you have a metallic or sweet taste, wash more until no taste is perceptible.

3. The plates will do when thus prepared for any process. There is no danger of injuring the bath if common care be taken.—Ed.]

TRANSFERRING POSITIVES TO LEATHER.

To the Editor.

Sir, — I take the earliest opportunity I have had to state the method I pursue in transferring positive collodion pictures to leather or cloth.

You must first get a good picture.

The leather I find best is patent calf.

The transfer varnish is —

Alcohol	1 ounce.
Nitric acid	2 drops.
Canadian balsam	The size of a pea.

Shake and filter into a separate bottle.

(The Canadian balsam was suggested by a friend).

Cut your leather to the size required; clean it with a little of the varnish, using an old silk handkerchief. Coat the picture with the varnish (as with collodion), but drain into the mixing bottle. Lay the picture on the table, take the cleaned leather in the right hand, and put it down on the picture gently, from left to right; then lift the picture, and you will see from the glass side if there is any air bubble or superfluous varnish beneath the leather (if so, it must be pressed gently out with the fingers); then dry it at the fire, or you may allow it to dry spontaneously.

When dry, pull the leather gradually off from one corner. You have now a non-reversed positive, that may be coloured and varnished.

To transfer on cloth is, in every way, the same.

This transferring process is easy and may be quickly done, but I find it difficult to describe.

These pictures may be used in a variety of ways, which will be readily suggested to any one — such as for putting in albums, for presentation books, &c.

How greatly would young men and women, in a foreign land, value the portraits of their aged parents or friends, in the bible they were presented with on leaving their fatherland!

Hoping the foregoing may be of use to some of your subscribers, I am, yours, &c. A. R.

Glasgow, May 11, 1859.

AMENDMENTS OF Mr. MAYALL'S FORMULA FOR COLLODION.

To the Editor.

Sir, — I have slightly modified the process as regards the bath. I was trying experiments to that effect when the paper was read, but could not decide until Wednesday last.

The iodide of potassium, to saturate the bath, renders the negatives more *intense* than iodide of magnesium. I dont stop for the moment to assign a cause; but of the fact I have no doubt. I have substituted nitric for acetic acid, to acidify the bath: it is more stable, and in the hands of the amateur, not so likely to fog or get out of order; perhaps it may not be quite so sensitive, but either is more rapid than anything I have tried.

I beg to send you a pound of the collodion, with the assurance that you will try it fairly. I may add that it has been excited *twelve months.*

Should any one who has got the time to spare take it up and make a quantity for sale, I have no doubt it would be a boon to our brother photos.—I am, yours, &c. J. E. MAYALL.

P.S. — The points to be insisted on appear to me —

First — "*In keeping qualities.*"

Second — "*Can be used with a decidedly acid bath.*"

Third — The extraordinary solubility of the excitants, iodide and bromide of magnesium, *in absolute (or nearly absolute) solvents*, and their power of absorption of water without deteriorating the quality of the film, or of themselves decomposing.

May 14, 1859.

A PLEA FOR METAGELATINE.

To the Editor.

Sir,—I find the addition of chloride of ammonium to the metagelatine, in the proportion of one grain to the ounce, reduces the exposure to about one-half — a stereoscopic plate, washed in a *quart* of water, requiring twenty to thirty seconds; if a smaller quantity of water is used, or if the plate be prepared without washing off the free nitrate, of course it is much more sensitive. I believe that, if tested, metagelatine would be found more certain than either albumen or *gum*, and if only required to be kept a few days, more sensitive — while for half-tone I think it excels all other dry processes.

If developed with iron, ten to twelve seconds is sufficient.—I am, yours, &c. D. HILL.

P.S.—If greater sensitiveness is required, there is no necessity for washing at all — but the plate will only keep about two days.

May 14, 1859.

[We by no means feel certain about the advantage supposed to be gained in sensitiveness by the addition of a chloride to the preservative agents, though it has been recommended by several skilful operators, including our present correspondent. Our own experiments certainly tend to show that considerable retardation in developement is the consequence, and what is of more importance, great loss of intensity. This point, however, requires further attention.—Ed.]

THE FOTHERGILL PROCESS.

To the Editor.

Sir,—On developing some plates prepared by the Fothergill process, I find the *sides* of the picture wanting in intensity, as compared with the rest of the plate. When viewed by *reflected* light, those portions show well as positives, whilst the remainder has the appearance of a solarised picture. Can you give me an explanation of this? I use a half-plate lens — or rather the front lens of an excellent portrait combination (reversed of course) — and half-inch stop.

The lens is in the *front* portion of the mounting, as the camera will not admit of my using it at the back. *The details of these portions of the picture come out well*, but are lacking in intensity.

I am also troubled with zig-zag markings — are these consequent on careless washing after the albumen? I use a two-grain bath after sensitising, instead of the four-drachm washing.

If you can help me out of my difficulties, I shall feel greatly obliged. —I am, yours, &c. LUX.

[The weakness of the edges of your picture is due to the length of tube behind your lens, which partially shades the plate, and thus, in effect, causes the oblique pencils of light to be of less area than those in the other parts. The use of a conical tube or fitting will obviate the defect.

The zig-zag markings proceed from your plate not being sufficiently drained *before* pouring on the albumen, a slight accumulation of the free nitrate of silver solution in those parts producing a cohering coagulum difficult to remove by subsequent washing. Drain more closely, and pour on the albumen to the edge of the plate placed uppermost in draining.—Ed.]

ANSWERS TO CORRESPONDENTS.

Mark, T. — Take the third on your list: it is far the best.

Received — "Alfred Keene." "O. G. R." "S. A. Morris."

Plassey — If you will send us a private letter with your name and address, we will put you in the way of obtaining what you require.

James McConnel — We are obliged for your good wishes, and would publish your letter, but it is too complimentary.

J. K. — See report of the North London meeting in the current number.

Crystal — We prefer *good flattened* crown glass to sheet or even plate.

One in a Fix (Southampton) — Per-chloride of gold is always acid to test paper. Use the double chloride of gold and sodium, and your difficulty will vanish.

Young Hypo — We do *not* approve of pouring on the fixing solution without first washing off the developer, especially if the latter, as is usually the case, contains a free acid; decomposition of the hyposulphite of soda ensues, and stains are apt to occur.

One in Trouble — Your paper sensitising bath is do doubt exhausted or materially reduced in strength, you cannot ascertain the extent by the specific gravity alone, because of course the solution now contains nitrate of ammonia, soda, or barytes, according to the salt used in preparing your papers. Add some crystals of nitrate of silver, or evaporate the bath to half its present bulk.

A. B. C. (Wolverhampton) — You cannot have read the Journal very carefully, or you would not have stated that nothing has been said about a collodion positive process; however, proceed as follows:—

Collodion —	Pyroxyline	4 grains.
	Alcohol	2 drachms.
	Ether	4 „
Iodising Solution —	Iodide of cadmium	$1\frac{1}{2}$ grains.
	Iodide of ammonium	2 „
	Bromide of ammonium	1 „
	Alcohol	2 drachms.

Mix to make one ounce of iodized collodion.

Nitrate Bath —	Nitrate of silver	200 grains.
	Distilled water	5 ounces.
	Nitric acid	2 drops.

Coat a plate with collodion, and immerse it in the bath, leaving it there all night, to saturate the bath with the iodide of silver, &c.; it ought then to be fit for use.

Developer —	Proto-sulphate of iron	15 grains.
	Nitrate of potash	10 „
	Water	1 ounce.
	Acetic acid (glacial)	30 minims.
	Alcohol	20 „
	Nitric acid	1 „
Fixing Solution —	Cyanide of potassium	10 grains.
	Water	1 ounce.

Photo-in-a-fix — See preceding reply. Perhaps your collodion is not good.—Another developer we can recommend as follows:—

Proto-sulphate of iron	15 grains.
Water	1 ounce.
Sulphuric acid	5 minims.
Alcohol	30 „

THE PHOTOGRAPHIC JOURNAL.

No. 96, Vol. VI.—JUNE 15, 1859.

We beg the serious attention of our readers to a great and growing evil—one upon which we have before made comments and expressed our indignation. We mean the attempts now frequently made, and too often successfully, to secure patents restrictive of the *free* enjoyment by photographers generally of various advantages that have been *freely* given to the public by the original designers and discoverers.

A letter from our esteemed correspondent, Mr. Rejlander, which we publish in the current number, is the immediate cause of our again noticing at the present moment a practice that, in our opinion, merits the condemnation and energetic resistance of all who wish well to our art.

In the last number of the *Journal of the Photographic Society*, we have a copy of the specification of a patent (without date attached) granted to Oliver Sarony, for "improvements in producing photographic portraits"—said improvements consisting in taking several negatives and printing portions from each. Now, even if it were not notorious, as however it is, that this method is, and has been for some time back, practised by several well-known operators, surely after the publication of the paper by Mr. Rejlander, which appeared in the Photographic Society's Journal upwards of two years ago, and the numerous copies of his works which have been sold, it is preposterous that any one should be able to obtain letters patent for an alleged invention which actually was more fully described in the paper mentioned than in the specification of the present claimant.

We trust that the Council of the Photographic Society will be induced to consider whether any means can be adopted by the society, as a body, to prevent this surreptitious acquirement of pseudo-patent rights interfering with the progress of that science of which it is the legitimate guardian.

Amongst the re-discoveries in photography we have to notice the use of glycerine, for the purpose of retaining the collodion film in a moist condition, either before or after fixing. In a paper which appeared in the last number of the Society's Journal, this is coolly put forth as a novelty, when, in fact, there is no novelty whatever either in the use of the material or the method of application. So far as appears, no notice to this effect was taken at the meeting where the paper was read; and the editorial foot-note of our excellent fellow-labourer rather tends to convey the notion that any experiments upon the subject were not published.

This is an error which we can rectify. Not only did we personally employ the agent ourself, but Mr. H. Pollock brought the matter prominently before the Photographic Society, when a tolerably long discussion ensued upon the subject, which was no doubt duly reported at the time. Mr. Spiller and Mr. Malone, we well remember, took part in the discussion—the former having worked in this direction; and, if we mistake not, Mr. Crookes also had, like others, employed this material, and subsequently abandoned its use for that of other syrups. Mr. Hockin also at one time availed himself of it. All these facts were published years back.

The great objection to the use of glycerine with free nitrate of silver in the film is the slow but sure reduction of silver, even in darkness,—thus producing a veiled appearance.

If the paper alluded to had any value whatever, it would be in suggesting the application of glycerine to prevent the drying of the film before it might be convenient to intensify or to fix the image; but even this had already been suggested by Mr. Gulliver, with syrup from honey or sugar, quite as effectually and far more economically; and we also find the same suggestion in a pamphlet published a few days since by Messrs. Murray & Heath.

We were not a little amused, the other day, at reading in the pages of a contemporary a communication from a correspondent, in which he mentions "what appears to him *a discovery*, and *a valuable* one, albeit exceedingly simple and obvious;" the discovery being that an iron developer is applicable to the Fothergill process. We fancy it is rather late in the day to make such a discovery; for did we not publish it, with all necessary details, *some months ago?*

While on the subject of the Fothergill process we may notice the fact of a negative being obtained upon a plate thus prepared by Mr. Hannaford, with an exposure of about a second of time, and exhibited by him at the last meeting of the North London Photographic Association. The extraordinary sensitiveness was, in the opinion of the operator, due to the conversion of all free nitrate of silver into a citrate, by the addition of a suitable salt to the albumen employed.

Mr. D. W. Hill has since worked in the same direction with the phosphate of soda: for particulars we refer to our correspondence.

In America the dry processes seem to have attracted the attention of some of the most enthusiastic followers of photographic science; and a gentleman, Mr. P. C. Duchochois (whose contributions to the pages of a transatlantic contemporary we have upon one or two occasions found worth while to re-produce with due acknowledgement of their source, of course), has suggested a preservative agent, which *prima facie* seems to have some probable advantages. This substance is glycyrrhyzine (the sugar of liquorice), as originally employed in photography by our countryman and friend, Mr. F. H. Wenham, the associate of Mr. Frank Frith in his Egyptian expeditions, and subsequently by Mr. Hardwich, to obtain intensity in collodion deficient in that quality.

Its use, as now suggested by the American gentleman we have named, appears to us as well worth a trial, particularly as he gives a formula for deriving it direct from the liquorice root in a state fit for the use of photographers, and which he alleges is capable of being rendered *insoluble* by immersion of the plate coated therewith in aceto-nitrate of silver solution.

The peculiar property of glycyrrhyzine to give intensity to the impressions on the collodion film is one that we regard just now as valuable, particularly if this quality be not too intimately associated with retardation of sensitiveness. We have had very general testimony of the exalted sensibility attained in most of the dry processes where a small portion of a soluble chloride or other analogous salt is mixed with the preservative agent; and, without pronouncing a decided opinion upon the point, we are

clear upon another in connection therewith, viz., that the addition of agents indicated above certainly decreases the intensity of the image produced: it is therefore not at all improbable, that the union of the two may result in each remedying the defects of the other; at any rate the experiment is worth a trial.

We have before now remarked upon the advantage of association in carrying out improvements upon any pursuit, and this fact is again prominently brought before us in the establishment of the American Photographical Society, which is already bearing useful fruit. To those who have been acquainted with American photographic literature for any little time, this fact is incontestible; in corroboration of which assertion we point to several short papers, none the less valuable that they are short, read at the last (the fourth) meeting of that body.

OUR ORTHOGRAPHIC CAMERA.

By The Editor.

Now that the "orthoscopic" principle of construction, as applied to landscape lenses for photographic purposes, appears to have taken a very strong hold upon the fancy of the public, a greatly increased demand for cameras with "swinging" backs has also concurrently arisen. There are, however, two or three very serious drawbacks to the general adoption of cameras possessing the peculiarity mentioned; the considerably increased expense of construction not being the least of them. The enhanced cost is owing partly to the fact that much additional labour is requisite in the manufacture, and partly because extra skill in the artisan being involved there are fewer hands available in producing them than is the case for ordinary instruments.

Another objection consists in the materially greater weight and bulk necessary for swinging-back cameras as now usually made.

The practical advantage to the operator in producing excellence of result by the adoption of the contrivance under consideration is, however, so incontestably manifest, that the writer has been induced to make an attempt (which he believes to have been a successful one) to reconcile the conflicting elements of discord, and acquire all the advantages without the objectionable bulk, and at a comparatively trifling cost.

The simplest mode of explaining the method of accomplishing the desideratum will probably be to state clearly first the conditions imposed, and then show how they may be fulfilled.

Where the objects to be delineated are arranged in various planes, at different distances, and distributed over the greater part of the area of the field of view, there is of course no remedy but a reduction of the aperture of the lens; but where they are arranged in such a manner that they are capable of being regarded as situated *approximately* in one plane, *inclined* to that of the sensitive plate, then a larger effective aperture of the lens may be employed, provided that the plate be inclined in an *opposite* direction, so that the part receiving the image of the object most distant from the operator is inclined *towards* the front of the camera, and that on which the image of the near object is depicted consequently further removed from it. For instance a row of trees or the side of a street placed diagonally towards the axis of the camera will illustrate the point under discussion.

It is essential that the axis of the lens shall be directed towards the centre of the plane of delineation (in our case the sensitive plate), but it is quite immaterial what form is assumed by the *front part of the camera*, provided always that it does not in any way interfere with the rays of light proceeding from the lens.

The following diagrams will probably tend to elucidate the propositions laid down.

FIG. 1

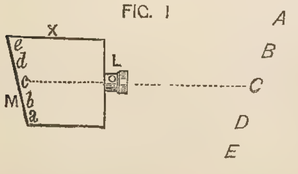

FIG. 2

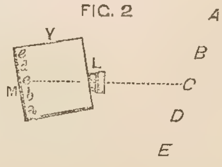

Let A,B,C,D,E, *Fig.* 1, represent a series of objects placed diagonally towards the axis of the camera, X, which is furnished with a "swinging" back, M; by inclining it as in the diagram, the images of these objects are represented pretty correctly in focus at *a,b,c,d,e,* the rays from the central object, C, proceeding axially through the lens, L. But if the camera be not furnished with a "swinging" back, it would still be possible to fulfil the conditions required if the camera were turned on its axis as at Y, *fig.* 2, provided that it were also possible to move the lens, L, out of the centre of the front of the camera, and also to give it an inclination from the perpendicular as shown in the figure.

The relative positions of the sensitive plates, M, in both cameras, X and Y, being identical with regard to the lenses and the objects, and that without being interfered with by the front portions of the respective cameras.

Most cameras for landscape purposes are furnished with *sliding fronts* in one direction at least; many have them in both directions, especially when the cameras are not square but oblong. Those already having these adjusting fronts require but a trifling addition to acquire all the requisite movements, but where the slidings fronts are wanting it will be necessary to supply them, in addition to which a piece of mahogany or other wood must be turned of a globular form; segments are then to be cut from opposite sides, leaving a central section of the globe about two inches thick, through which a cylindrical or conical hole is to be made, as shown in *figs.* 3 and 4, the former where the lens is desired to slide for

FIG. 3

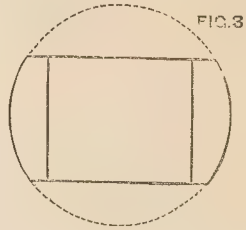

FIG. 4

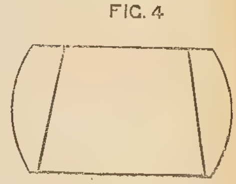
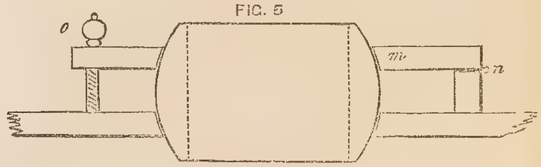


adjusting the focus, the latter where this is not required, but the flange of the lens can be screwed on to the flat surface of the segment of the globular piece of wood.

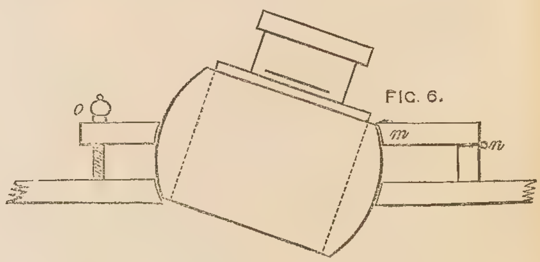
This portion of a globe is made to work in a hole in the camera front *slightly smaller* than the diameter of the globe, the edges of the aperture being armed with black velvet, partly to ensure a smoothness of movement, and partly to prevent even the smallest leakage of light. The globe is kept in place by means of another

FIG. 5



thin piece of wood, as shown at *m*, *figs.* 5 and 6, having a similar

FIG. 6.



aperture to that last named, and which is hinged at *n*, and capable of *slight* compression by a screw at *o*. The whole then acts upon the ball and socket principle; the compression by the screw serving to keep the lens steady in any position to which it has been previously adjusted. When the lens in use is but small, a spring of some kind may be substituted for the screw, and thus no time lost in the adjustment.

It will be seen that by the contrivance above indicated every thing at present attainable by the camera having a "swinging" back in *both directions* is accomplished, while the additional bulk and weight to the ordinary cameras are trifling, and the cost but shillings where the "swinging" backs cost pounds.

DRY PROCESSES AND THEIR DIFFICULTIES.

By the Rev. WILLIAM LAW.

[Read at the Meeting of the Birmingham Photographic Society, 31st May, 1859.]

GENTLEMEN,—When you were pleased to confer upon me the honorary membership of your Society, I felt that the acceptance of your kind compliment involved the proffer of my services in contributing, so far as the results of my experiments might enable me, to your common fund of information. Societies of a scientific character must seek advancement, not in the *prestige* of high connections or in the mere *patronage* of honorary members, but in the free interchange of ideas, in the intelligent and patient grappling with hard facts, and in carefully-performed experiments leading to deductions by which science may be elucidated and art improved. Distance precludes the possibility of my frequent presence at your discussions, but, whenever I have joined them, the effect has been to strengthen my opinion that the Birmingham Photographic Society embodies within it the elements of success, and the report of its proceedings will be found, I apprehend, to keep the public *au courant* with the progress of the art of photography. I will only add on this head that my connection with your Society has been to me an advantage as well as a compliment, for I have never attended its meetings without having been brought into contact with skilled chemical investigators as well as enthusiastic and thinking operators, whose acquaintance I am glad to have made.

My paper, last year, was intended to explain and remove some of the difficulties which accompany initiation into the mysteries of the camera. Of these, my limits forbade my taking little more than a "bird's-eye" view; I could only select a few of the more prominent and common. A large portion of the field then entered remains as yet unexplored. Care and skill, patient investigation, reading, and unceasing inquiry respecting the merits of new processes and the failures of old, can never be dispensed with by the amateur who wishes not only to obtain satisfactory results, but to know the *rationale* of his success, and to keep pace with the progress of this complete branch of science. And when we consider the play of nicely-adjusted chemical affinities which are brought to bear in the production of a finished picture, and take into account the fact that the collodion and sensitising bath are actually undergoing chemical decomposition with each individual plate we prepare, we do not feel surprised that a large proportion of the communications which fill the pages of our photographic publications should involve seeming contradictions, and solicit explanations of facts unaccounted for and of difficulties unremoved. And here I am brought at once to a point of the greatest possible importance in all processes, either moist or dry, and that is the *capacity of the sensitising bath.* It is the worst possible economy to be sparing of nitrate of silver, for it must be borne in mind that the sensitising of a plate necessarily involves the abstraction of as much nitrate as is required to form the sensitive film. The silver bath is, if small, very rapidly and seriously weakened. Small upright glass baths for stereo-sized plates may be, if duly used, even like "Godfrey's Cordial" to mother's, "a real blessing" or a bane. Suppose for instance, an amateur employs a glass bath of the capacity of eight ounces, requiring half an ounce of nitrate of silver for bringing it to the normal strength; he prepares a dozen plates wherewith to test the value of some dry process; the result is satisfactory, and he sends forthwith to his favourite journal a grateful laudation of the discovery thus triumphantly tested. Now "comes the tug of war" which leaves our champion crest-fallen and forlorn. He has perhaps a friend, who is an advocate not altogether unprejudiced of some more ancient process which has yielded him the like satisfaction, and of which he considers the other a mere upstart rival. Our first acquaintance we will suppose a Fothergillian, his friend a Norrissian or a Taupenotian. The plates are duly prepared, the collodion and bath are only it may be a fortnight old, every step is taken *en regle*, our friend gains confidence, and, with that perfect satisfaction "which makes a heavy burden light," away go the companions to some lovely nook, of which the selection had long ago been carefully made. In due course we see them again in the dark room, watching with eager eyes, though varying in expectation, the developement of the first plate. There is a suspicion, ill-concealed by our sanguine Fothergillian, of *under exposure*, but the total absence of *density* is anomalous with this supposition; the plate is washed, and receives a fresh dose of developer, but, alas! the result is only a patchy mass of irregularly reduced silver, showing beneath a dirty veil, the bare tracing of a beautiful shadow. Alas! *Ex uno disce omnes*, every attempt results in similar disappointment; the whole batch of plates exhibit a lamentable failure. The Fothergillian is confused; the exultation of his Norrissian acquaintance is tempered by the claims and sympathies of friendship; but, when the last plate is on the point of being given up, he cannot restrain a gentle nudge of the elbow, with "how now old fellow!" as its expressive vernacular accompaniment. Now the only exaggeration that our description contains is, that the first batch of plates were all *equally* good, and the other all *equally* bad. *There was a difference*, to a keen and *experienced* eye, quite perceptible, between the first and last of both lots, and this was mainly due to the *varying strength* of the nitrate bath. My advice is that no amateur should ever think of making a smaller quantity of nitrate solution than forty ounces. In a bath of stereo-size, the deterioration from the cause assigned, although not so rapid as our supposition would imply, must never be overlooked by those who would wish to maintain a normal condition of sensitised surface. After preparing half a dozen plates, it will be well to have fresh recourse to the forty-ounce stock bottle. For stereo purposes I always on this account employ a glass bath adapted for plates 10 in. × 8 in. The advantage is apparent by the simple application of arithmetic, which will prove that the same abstraction of silver that would reduce the strength of an eight-ounce bath to fifteen grains to the ounce, would still leave a forty-ounce bath with twenty-seven grains to the ounce. To those who would prefer the hydrometric test, and trust to specific gravity indications for keeping up the strength of the bath by the occasional addition of fresh crystals of nitrate, I would strongly recommend a little graduated and loaded tube, by Negretti and Zambra, of which I have very satisfactorily tested the accuracy and value.

It will be unnecessary for me here even to allude to the importance of clean plates, or to repeat my directions for insuring their perfect cleanliness; but I must not omit to notice one cause of stains which is not so generally recognised as it ought to be, but which nevertheless is by no means unfrequent, and that is, *contact with the fingers in removing the plates from the sensitising bath.* If the plates, after being raised, are left some time in an upright position to drain, the stain will seldom extend sufficiently beyond the margin of the film to damage the picture; but it is always advisable to have at hand some finger guard, which can be easily made of thin sheet gutta percha, which are very efficient and inexpensive.

To those who employ Taupenot's process, and experience the annoyance of blistering of the film or developing, I would recommend, not only the perfect cleansing of the plates, but the application of a substratum of albumen one ounce, and distilled water two ounces, well frothed and filtered through sponge in the usual manner. This insures the adherence of the film to the plate, prevents blisters, and admits of the employment of collodion which might otherwise be unsuitable. The utility of such a substratum has been recognised and *re-discovered* several times by exponents of dry processes within the last two years; but if priority of publication be regarded as supporting the claim of original discovery, reference to my communication in Vol. II. of the *Journal of the Photographic Society*, pages 46 and 47, September, 1854, will very satisfactorily dispose of this matter. Since the date of my letter alluded to, I have been in the constant habit of employing substrata, either of albumen or isinglass (as therein described and recommended), and with invariably satisfactory results.

Further experiments with the plates of the Birmingham "Dry Collodion Plate Company" have confirmed my opinion of their certainty and sensibility, and their general perfect adaptation to the wants of the travelling photographer; and to those who lack either time or skill to prepare their own dry plates I strongly offer the recommendation to procure a supply of these, as far less liable to cause failure and disappointment than any others at present in the market. Of all bought dry collodion plates, these are by far the most sensitive. My own practice for the last few months has been entirely confined to a modification of Taupenot's process and to Fothergill's—the former the *slowest*, and the latter, in my hands, the most rapid of all the dry processes which I have tried. Both these have yielded me most excellent results, which I shall be happy, when I am able to attend your meeting, to exhibit to the members of your Society.

The former process is conducted as follows:—The plate is cleaned, and the collodion poured on in the usual way; when the film is well set, the plate is plunged into a bath of distilled water, in which it is left until, on being raised, all streakiness has disappeared. After closely draining, iodised albumen is poured gently on its surface, and allowed to remain two minutes. The plate is then drained and dried, and is ready for sensitising in the following bath:—

Nitrate of silver .... 60 grains.
Distilled water .... 1 ounce.
Glacial acetic acid .... 30 minims

Saturate with iodide of potassium in the usual way and filter. Leave the plate in this bath for two minutes; then wash off all the free nitrate in *hard* water, which must be finally displaced from the surface by pouring thereon a drachm or two of distilled water. Then drain and dry. Develope by immersion in a saturated solution of gallic acid, and two drops to the ounce of a solution of

Nitrate of silver .... 20 grains.
Water .... 1 ounce.
Glacial acetic acid .... 10 minims.

The exposure is, in good light, for general landscape work, two minutes and a-half to three minutes, with one of Ross's four inches and a half focus stereo lenses.

This modification has proved to me far more satisfactory than the original Taupenot process, which it excels in its adaptation to the effects of the aërial perspective, which are charmingly rendered in some of my best pictures. The developement sometimes requires upwards of an hour, but care must be taken not to spoil the picture by *needless accumulation* of the black deposit, which would ruin the vigour and the gradation of tone which distinguish a good picture from what have been not unaptly termed "smears of soot and whitewash." For quick work my favourite process is Fothergill's, in which I follow the directions usually given, and seldom use more than half an ounce of distilled water for equalising the free nitrate left on the plate after its withdrawal from the bath. Plates thus prepared will keep a full month in summer without showing signs of discolouration, and yield impressions of great delicacy and vigour. I find a neutral bath is generally recommended for this process, and no doubt the sensitiveness of the plates is thereby considerably exalted; but neutral baths are very liable to get out of order, and soon begin to show an alkaline reaction upon test paper, so that I always make a point of adding sufficient acetic acid to a new bath, prepared with *fused nitrate* (which I always employ) to show a reaction of the opposite character. The only difficulty with the Fothergill process, and that of comparative unfrequent occurrence, is to check the occasional tendency of the developer to find its way under the film. This is entirely obviated by the employment of the albuminous substratum already alluded to, and from the constant use of which I have never yet found my nitrate bath manifest the slightest indication of discolouration.

Compared with the ordinary Taupenot process the Fothergill excels in sensitiveness in the proportion of three to two. For printing transparent positives on glass I prefer the Fothergill plates to all others. The tone is that of a rich brown black, admitting of the most perfect gradation and harmony of light and shade. I have applied these transparencies to the magic lantern, to which they are exceedingly well adapted, and there is no danger of that objectionable greenish tint inseparable from the employment of the Taupenot plates for this purpose.

And now, gentlemen, I must conclude my very hastily-written paper with an apology for the meagreness of this attempt to throw my mite into the treasury of your greater abundance; begging you to deal gently with all the deficiencies you may be able to detect, and to attribute more to lack of present leisure and opportunity than of kindliness of feeling and sincerity of intention that I am unable to interest you more or serve you better. With the final expression of my sincere regret that the state of my health necessitates my requesting your secretary to read this paper instead of being present with the apparatus and the results, which it was my intention to have submitted to your examination, I will couple the assurance that I shall be happy (D. V.) during your next session to take an early opportunity of bringing before you the apparatus and manipulations which were to have illustrated and explained this paper.

THERMOGRAPHY v. PHOTOGRAPHY.

Calorific reductions as a means of Producing Images upon Sensitive Paper.

By M. Niepce de St. Victor.

The following experiments are an extension of those of Moser, Knorr, and Draper: to the facts already established, I believe I have added a great number of others both new and interesting, of a nature calculated to throw some light upon this important class of phenomena.

If, upon a metal plate heated in contact with boiling water, we place first an engraving on a printed paper, then a sheet of paper impregnated first with nitrate of silver and afterwards with chloride of gold, we obtain a violet blue image of the blacks of the engraving or of the printed letters. If the paper is only impregnated with nitrate of silver, the whites only of the engraving are reproduced in a bistre colour.

A metal tube heated to the temperature of 212° F, the opening of which covers the engraving placed upon the sensitised paper, produces the same effect as the warm plate.

With paper prepared with the salts of silver and gold, and with the plate warmed with boiling water, large printed characters are reproduced at a distance of several *millimêtrès;* but the image is not produced if we interpose a thin plate of mica, metal, or even a piece of *papier végétal.*

If we place a paper printed with large letters between two glass plates, and warm the whole to a temperature sufficient to slightly scorch the paper, upon removing the paper we perceive the letters have left their imprint upon the glass. If upon this imprint we place a sheet of paper prepared with the salts of silver and gold, and warm the whole upon a metal plate, heated with boiling water, we obtain a new image, as if the sensitive paper had been placed upon the printed characters themselves.

Designs traced with writing ink, black lead, or charcoal, are not reproduced when they are traced upon ordinary paper, but they are produced upon *papier végétal.*

An unvarnished positive photographic image upon collodioned glass, formed by reduced iodide of silver, has printed upon sensitised paper, under the influence of heat, many consecutive images of the "darks;" the last proofs being the sharpest and most vigorous.

Some tiles and porcelain plates (glazed) with black letters or painted in various colours, and passed through the furnace without being enamelled, gave impressions; but letters and designs covered with enamel, gave none.

Tissues shaded with black and white, or with varied colours, impressed their images upon sensitised paper; but the images were very variable. In general the blacks printed the best, but frequently the whites also; the image of every colour has a character and intensity peculiar to itself, the variations observed depending doubtless upon the nature of the colour. The colours produced by the same colouring matter applied with different mordants in succession, were printed very unequally and very differently; Madder, for example, which gives upon cotton a red with alumina; violet, with a salt of iron, a deep brown or a red brown, according to the relative proportions of alum and iron; the red was printed stronger than the other hues upon paper prepared with chloride of gold. In the case of whites obtained upon coloured grounds by means of a *discharge*, the whites as well as the grounds left their images upon the sensitive paper; upon cotton dyed with indigo blue, the blue ground is reproduced, but the whites are not; while in those dyed with Prussian blue, it is on the contrary the whites that are reproduced. If we spread upon paper or porcelain separate bands of indigo and Prussian blue, only the bands of indigo will be reproduced, never the Prussian blue. Another fact also proves the preponderating influence of the peculiar nature of each colour and ink. I have seen two engravings of the same drawing, but printed with different inks, one gave a positive, the other a negative image upon paper sensitised with chloride of gold.

I shall conclude with some remarks upon the preparation and use of sensitive papers in thermography.

Prepare two solutions, one of fused nitrate of silver, of the strength of one per cent., the other of chloride of gold of the same strength. The paper sensitised with nitrate of silver only is obtained in the ordinary way. To prepare the paper with both salts of silver and of gold, float upon the solution of nitrate of silver a piece of Berzelius's paper, holding it by one corner, dry it slowly without scorching before a fire, and when dry pass it through the solution of chloride of gold, floating the same side that was placed on the silver solution, dry it again without the temperature attaining that of boiling water, because at this temperature the paper becomes discoloured.

To obtain an image, place an engraving with its back upon the plate warmed by boiling water, and lay the sensitised paper upon the engraved side, and cover it with a plate of glass of several *millimêtrès* in thickness; upon looking through this glass we see the image appear in a few minutes. The image is clearest when the paper is very dry and not over sensitive; if it does not become sufficiently distinct, it may be strengthened by exposing the sheet of paper to the heat of a clear fire. If it be very vigorous, and stands out clearly from a ground slightly coloured, it may be fixed by treating it with a solution of hyposulphite of soda, which removes those portions of the salts of silver and gold which have not been reduced by heat. The paper sensitised with the double salt of

silver and gold will not keep in the dark, it must be prepared as wanted and used immediately. Paper impregnated with a solution of nitric acid of a strength of one per cent., or with a solution of potassium of ten per cent., is sufficiently sensitive to yield thermographic images, but only at a temperature much above 212° F.

I attempted to obtain images in the focus of a lens which concentrated the rays emanating from a heated object, but the result was always negative. I have not yet ascertained if the images formed in the focus of a concave mirror are more active. At present it appears to be an indispensable condition of success, under certain circumstances, that the radiation be direct without the interposition of a screen.

The action that produces the thermographic image is, doubtless, a very complex one; calorific radiations play an important part; but the solid vapours emanating from the heated object may also intervene.

But in the case, at least, of the medals and a dry stamp which were reproduced, notwithstanding the interpositon of a thin continuous plate of mica, silver or copper, provided the pressure was sufficiently strong, and the temperature high enough, it must be understood, that the action of heat preponderates; and it appears to me established, that a high temperature produces, under certain circumstances, facts analogous to those we see produced daily by light, such as the fading of colours, the reduction of the salts of gold, silver, &c.

Luminous and calorific action may sometimes coalesce or unite to produce simultaneously the same effect, but they are often separate and distinct, as proved by the experiments of MM. Bouillon and Sauvage.

These experiments were made previous to the month of January last, in the presence of witnesses.

IMPROVEMENT IN PHOTOGRAPHIC ENGRAVING.

By M. Berchtold.

Heliography, invented by Nicéphore Nièpce some thirty years ago, has been the starting point of all the beautiful discoveries which during the last fifteen years have brought photography to an unhoped-for degree of perfection. Nièpce had from the first attempted the engraving of photographic images, and in 1829 had partially succeeded, but it has remained unperfected to the present day.

The results at which Nièpce arrived, were, in a photographic point of view so admirable, and the method by which he reproduced a drawing, engraving, or view, taken in the camera, already so perfect, that it seems surprising it has remained so long neglected.

The proofs obtained by M. Nièpce's process are very beautiful; especially if, instead of engravings or drawings, we employ photographic positives or negatives. Still there is a great difference between these proofs and the photographic image obtained direct. It is therefore important to note this difference in order to appreciate the theory of heliographic engraving.

The photographic proof is formed by the colouration of a substance under the influence of light, the varying intensity of which gives more or less strength to the tones of the image, and consequently gives the image and effect of the object.

In the heliographic images obtained by means of bitumen this is not the case. The design is not formed by the colouration of the substance, but the luminous rays modify the varnish, so that it becomes more or less insoluble according to the intensity or duration of this action. By means of a subsequent washing with a suitable solvent, the portions of the varnish which the light has not attacked are completely dissolved, while upon those parts which have been impressed by the light, the solvent acts proportionably to the degree of that action.

The gradation of tint, which is also very perfect in these images, is therefore due to a greater or lesser quantity or thickness of the varnish, and not to its colouration, which remains the same after exposure to the light.

In the numerous attempts at engraving which have been made since Nièpce to the present day, the metal laid bare in the darkened portions of the design has been acted upon and bitten-in by an acid, or by means of the galvanic pile; and to impart to the plate the *grain* necessary to make it retain the ink, recourse has been had to a process employed by engravers, which consists in dusting the plate over with powdered resin, which adheres to the plate when it is warmed, and protects it from the action of the acid.

Reviewing this process, and considering the manner in which the half-tints of the heliographic image are formed, it is easy to understand that the powdered resin which spreads itself equally over the whole surface of the plate must have a peculiar effect upon these half tints, which are already covered with a certain thickness of varnish, rendering the results very unsatisfactory.

Reflecting upon this objection, I have endeavoured to produce a *grain* by the direct agency of photography, and after various attempts I have succeeded in producing it upon the positive proof, by means of the *roulette* employed by engravers.

This method, which yields an excellent, fine, and regular grain, produces admirable results. It also presents many important advantages: first, it simplifies the heliographic operations, as exposure to light gives the complete image at once, such as the acid produces subsequently by biting into the metal; then it permits of the employment of caoutchouc to consolidate the varnish, which when the plate is warmed to form the *grain* by resin, cannot be adopted, as the caoutchouc is disorganised at the temperature required.

A plate of glass is thinly coated with an opaque varnish. By means of an engraver's ruling machine a series of fine lines is traced in one direction over the whole surface of the plate. When the metal-plate coated with its bitumen varnish has been exposed to light under the negative, before it is washed, the ruled glass-plate is substituted for the negative, and the light allowed to act. Wherever the bitumen has been acted upon, while it was under the negative, no new action is affected by the light passing through the ruled plate, because the bitumen has become insoluble, but only on those parts which have been partially or not at all influenced by light. After sufficient exposure to light the ruled glass is lifted and turned in an opposite direction—that is, placed at right angles to the first lines, and again exposed to light, but for a shorter time than before. The ruled glass is next placed diagonally to the squares obtained, and repeated in the opposite direction, the time of exposure decreasing with each change of position. In this manner a multitude of fine points are obtained over the plate, but only in those parts where they are required. The whites retain their purity throughout, while the grain, on the half tints, instead of being equal is modified.

NOTICE OF A DIACATOPTRIC TELESCOPE.

By M. Babinet.

The substitution of mirrors of silvered glass for metallic mirrors, opens a new field to optics and astronomy. M. Foucault, by a process he has invented, can at pleasure modify the spherical surfaces of glass mirrors, hence results an unexpected perfection in images and apertures till now deemed impossible. Photographic apparatus, as well as the telescope and microscope, are assured of important improvements.

The construction which forms the object of this note is one of those which had no chance of success before M. Foucault had found the means of modifying at will the curvature of his reflectors. It consists of receiving upon a concave mirror the rays previously rendered convergent by an ordinary large achromatic *objective.* We can thus easily reduce the lunette to one-fourth of its focal length. It becomes a sort of Newtonian telescope.

The mirror with hyperbolic surface is placed at one-fourth of the focal distance of the achromatic objective, with an opening equal to three-fourths that of the objective. If the surface of mirrors remained spherical, it is evident that the accumulated aberrations would render this combination inadmissible. I shall therefore only consider it as a question to exercise students upon.

Since I have seen the conclusive results obtained by M. Foucault in the realisation of surfaces demanded by the special requirements of every instrument, I have revived the old idea of the diacatoptric combination now under consideration, and I am assured that there is no obstacle to the success of this shortened telescope. I may add, that the preservation of the polish of the mirror, and the absence of currents of air which disturb the eye in open Newtonian tubes, are points greatly in favour of this new arrangement.

Meetings of Societies.

LONDON PHOTOGRAPHIC SOCIETY.

The last meeting, previous to the recess of this Society, was held as usual, on Tuesday, the 7th instant, at the Society's Rooms, New Coventry Street—P. Le Neve Foster, Esq., V.P., in the Chair.

The Chairman stated that in consequence of very recent and severe domestic affliction the Secretary was unable to attend the

meeting, and the minute book of the Society, which was locked up and the key in the Secretary's possession, could not be got at, it would therefore be necessary to dispense with the usual reading and confirmation of the minutes of the previous meeting until the next gathering.

The same cause, the Chairman stated, had prevented the preparation of the usual paper, so it depended upon the members present to bring forward matter for discussion to fill up the blank. Mr. Malone had brought a camera for exhibition and he would probably make some remarks upon it.

The CHAIRMAN also handed round for examination a number of proofs, produced by Mr. Horsley, by what he termed a pigment process, and almost identical with that discussed at a previous meeting, and brought before it by Mr. Pouncy. In the present case various pigments were substituted for carbon.

The proofs were narrowly examined by most present, but did not elicit any public remark. The same faults noticed formerly in Mr. Pouncy's productions were apparent in Mr. Horsley's, viz., want of half-tone, imperfect aërial effect, and white parts not quite free from granulation. They were certainly inferior to the best of those exhibited by Mr. Pouncy; but the capabilities of the process, or rather variation of the last-named operator's method of operating, were apparently equal, if not superior, if performed by an equally skilful manipulator.

Mr. MALONE exhibited and described at great length a camera, recently constructed for him by Mr. Ottewill under the direction of the former. It was made of Moulmein teak, with a rigid tail board having a long screw adjustment. The body of the camera being separable from the tail-board, was formed upon the folding bellows principle. The front was made sliding, only in a perpendicular direction, and the back *swinging* in only one direction, that is upon a horizontal axis. The dimensions were such as to admit as a maximum of a square plate of glass 13½ inches siding being employed, smaller sizes being of course available by the use of appropriate inner plate frames. In order to increase the rigidity when in use, a brass rod was made capable of attachment by screws to the upper part of the frame work, and the amount of adjustment for focal length was from three or four to about thirty inches, thus adapting it to serve with various lenses, either single or compound. The cost was stated, in reply to a question to that effect, to be about £12.

Mr. MALONE was under the impression that the kind of wood of which it was constructed was one very little known, and that several points to which he drew attention were novelties, especially the method of mounting the focussing screen. He considered it a great advantage to have a rigid instead of a folding tail-board, and one that could be easily detached from the body of the camera, thus the body could be carried in one hand and the tail-board in the other. He thought it requisite for a photographer to be "armed at all points," and considered that, as regards a camera, with one like that before the meeting he would be so armed. He asked to have it found fault with, that he might ascertain if it were possible to improve it.

The camera evidently did not meet with the approbation the owner anticipated, while some jocularly remarked that instead of being "armed at all points" with such a camera, one might rather be considered as "loaded at all points."

A MEMBER, with whose name we are unacquainted, stated that he had recently purchased a camera of M. Jamin, of Paris, about the same size as Mr. Malone's, very similar in construction, and having all the advantages claimed for the latter, at a cost of six pounds.

Mr. HEATH protested against the time of the meeting being occupied with a long description of that which embraced no novelty whatever, and with which those present, being photographers, must be all perfectly familiar. He disputed the principles laid down by Mr. Malone as desirable in the construction of cameras, and accused him of inconsistency in advocating sliding fronts and swinging backs, and yet leaving half of these advantages unacted on, by adopting these movements in only one direction. If good at all, they were clearly desirable in both directions.

Mr. MALONE asserted that by the course he had adopted he had shown his discretion as well as his judgment. One might have too much of a good thing; it was not advisable to encumber one's self too much, and he thought he had hit the happy medium.

Mr. SEBASTIAN DAVIES made some observations relative to the futility of Mr. Malone's supposed remedy for preventing the entrance of light at the upper part of the dark slide.

Mr. SHADBOLT would find no fault with Mr. Malone's camera, for the simple reason that he differed in opinion with that gentleman upon nearly every point of construction advocated by him; consequently it was impossible for them to regard it from any thing like the same point of view. There were, however, two points upon which he would trouble the meeting. His occupation naturally entailed the most intimate familiarity with the qualities of different kinds of wood, but especially those of mahogany, and also of teak, that of which Mr. Malone's camera was made; which was not, as the latter supposed, little known, but consumed in very large quantities, chiefly for shipbuilding purposes, and also for the construction of railway carriages. The kind of teak wood in question was not the African wood, but the production of the East Indies, and being shipped at Moulmein was technically known as Moulmein teak. Its specific gravity is about equal to that of the average of mahogany from the Bay of Honduras, so that there is little or no advantage in point of result. It is rather more brittle than mahogany; but as the grain is generally almost universally extremely straight, its "standing" qualities are good, and the character of the wood very uniform. With mahogany the grain is often much twisted, giving rise to the beautiful appearance known as "figure;" but some mahogany from Honduras had a grain even superior to that of teak in straightness and "standing" qualities; of that kind all coach panels are made, and it would be seen at once that, as they are subjected to great variations of temperature as well as moisture and dryness, the test was one greater than cameras are liable to. He therefore preferred this kind of mahogany to any other wood whatever for cameras, though he thought that next to it teak was preferable, and even better than "figury" mahogany, which he often noticed was selected by those who thought more of appearance than utility.

The second point on which he would remark was relative to a "swinging back," upon the advantages of which opinions were divided. He thought them highly useful; but without a movement in both directions more than half the value would be sacrificed. If he had but one movement, it would be just the opposite one to that adopted by Mr. Malone. He had contrived a very economical but efficient substitute for a swinging back, adaptable at a trifling cost to cameras already in existence, and proceeded to describe it by aid of a diagram; but as full particulars will be given in a separate article, it is needless to repeat the description here.

Mr. ENNEL advocated the use of doors opening by an external lever for the dark frames, instead of sliding shutters as generally employed. He also described an arrangement he adopted for his focussing screen, which he never removed from his camera; but it being kept in place by means of elastic bands of india rubber, which always brought it up to its bearings, he was able to slide in his dark frames between the focussing screen and its bearings, the elastic bands giving way sufficiently for the purpose.*

Mr. MALONE, in reply, illustrated the old saying that—

"A man convinced against his will,
Is of the same opinion still."

Mr. SHADBOLT wished before parting to request the attention of the Council, to consider whether it might not be possible for it, as a body, to exercise some kind of supervision relative to the unjust acquisition of patent rights, inflicting serious injury on photographers. It might be possible to prevent parties obtaining patents for matters to which they had no right, by constantly watching the applications for patents, and giving due notice of the same, by which the attention of those interested might be attracted to the point.

Mr. HUGHES also urged upon the Council the advisability of giving members due notice of the probable subjects to be discussed at the meetings.

The adjournment until next November was then announced.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE last meeting for the session of this Society was held on the evening of Wednesday, the 1st instant, at the Rooms of the Literary and Philosophical Society, Mr. MABLEY in the chair.

George Shadbolt, Esq., was elected an Honorary Member of the Society.

Some photographic portraits, life size, enlarged from small negatives, by Mr. D. A. Woodward, of Baltimore, United States—he having patented a camera for the purpose—were exhibited to the meeting, and much admired for artistic effect.

Mr. WARDLEY exhibited a small orthoscopic lens by Ross, for covering ten inches by eight inches, the peculiarities of which he explained to the meeting, and exhibited some prints produced by it, showing the capabilities of Mr. Ross's lenses. He (Mr. Wardley) thought them better than Voigtlander's and quicker.

* This appears a very ingenious and advantageous arrangement.—ED.

A general discussion on the merits of the various lenses, by different makers, took place, and most of the members thought no lens for landscapes had yet excelled Lerebour's, and for architectural subjects Voigtlander's. Mr. Wardley exhibited a developing stand with a circular top, which was considered more convenient than the triangular ones.

The CHAIRMAN called the attention of the meeting to a sort of deposit which some of the members had experienced upon collodio-albumen plates during the developement, when a general discussion took place on the subject.

Various general subjects were discussed, and after a vote of thanks to the Chairman, the proceedings closed. Being the last meeting of the session, and the summer so far advanced, the attendance was small.

CHORLTON PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Society was held in the Chorlton Town Hall, on the evening of the 8th instant, Mr. Nicholson, Vice-President, in the chair. The minutes of the last meeting having been read and confirmed,

The CHAIRMAN said that, as the last meeting afforded very little time for the discussion of Mr. Draffin's paper on the Dry Processes, it had been considered desirable that another opportunity should be offered to members to express their opinions and experience on the subjects under review. Opinions ran strongly amongst them in favour of both Taupenot's and Fothergill's processes; and as the Society contained skilful operators in both, he hoped that the discussion would elicit information that would be serviceable to all who were interested in out-door work. He thought every one's experience would testify to the excellence of the pictures obtained by careful manipulators in both processes, and this opinion was well illustrated by the specimens Mr. Draffin had sent. Selecting the best examples of each, viz.—*The South Aisle of York Minster* (Taupenot), *St. Mary's Abbey* (Fothergill), and *The Hospitium, York* (Hill Norris), he thought the relative merits of the several processes were pretty equally balanced. Assuming, therefore, that the *results* were equal, their choice would be limited by those considerations which came next in importance, and these would be their *preservative* and *sensitive* properties, and the *ease* and *certainty* of manipulation. On these points he would invite discussion. Their Secretary, the cause of whose absence he much regretted, had sent him a letter, which he would at once read.

Trefrew, June 4, 1859.

DEAR SIR,—I regret very much being unable to attend the next meeting of our Society; but you know how much I have been a sufferer for some months past, and how imperative it had become that I should seek rest and fresh air. I hope, however, that my present leisure may be productive of some interest to our future meetings.

Though I write this to you, I should be glad if you will read it to the Society, as I purpose making a few remarks upon Mr. Draffin's paper, which was read at our last meeting, and the discussion upon which was adjourned.

Mr. Draffin admits that for *some* kinds of work the three processes, Taupenot's, Fothergill's, and Hill Norris's, are equally good, but that for in-door or dark subjects Taupenot has a decided advantage over Fothergill, inasmuch as it suffers less from over-exposure, and yet is quicker in the camera! I submit that the process which answers as well as another under one circumstance will be quite equal under any other, if both receive equal justice in their preparation. Can Mr. D. say this was the case in his *Interior of York Minster*, where the Taupenot picture was exposed three-quarters of an hour and the Fothergill four hours? Few who have had any experience in the two processes will believe that the insensitiveness of the Fothergill plate was attributable to the process. Mr. D. seeks to illustrate his argument by showing us a picture he obtained, by the Taupenot process, of an old black chest, in a dark room in York Minster, adding that "Fothergill was a failure—completely so." If Mr. D. wished to have proved his case from this experiment he should have submitted the Fothergill picture as well as the Taupenot. How do we know that the fault was not more in Mr. Draffin than in Mr. Fothergill?—that the exposure was not over-timed? and I need hardly remind you that both reason and experience proves to us that the most sensitive surface requires the greatest nicety in regulating the exposure—or that dirty marks, from imperfect washing, was not the cause of failure.

In the picture of *St. Mary's Abbey*, the Fothergill is stated to have been exposed one minute, the Taupenot thirty-five seconds. The latter contains the figures of men filling a wheelbarrow, clear and distinct; in the former, the wheelbarrow and men are gone. Surely, if they were clear and distinct in the thirty-five seconds' picture, some decided trace of them should have been seen in the one which took only twenty-five seconds more. To me it seems clear that the pictures were not exposed simultaneously, and therefore have no value as a *comparative* experiment.

One very serious drawback to the Taupenot process is the blistering of the film. Mr. D. proposes as a remedy that the plate should be slightly warmed before coating; but unless he has omitted to act on his own suggestion, the specimens sent by him and developed at the last meeting, only proves that the old difficulty is not so easily or so certainly overcome. Several of the blisters certainly subsided as the plate dried, but still many show on the print which I took from it. With this exception the print is very beautiful; and I feel sure if Mr. Draffin will bestow the same care, skill, and perseverance on Fothergill that he has done on Taupenot, he will soon be brought to admit that the former will yield him more half-tone and detail than can be got by the latter. I admit that Fothergill requires great care in manipulation, and is altogether more difficult to manage than Taupenot; but if we are to discard it on that account, there will be an end to all progress. I do not wish to disparage the older process, by which many operators obtain excellent results; but I submit, when the question of sensitiveness, now much increased by the gum and chloride of ammonium modifications, is taken into consideration, along with the results obtained, no dry process at present before us offers so many inducements to operators as the one submitted to the public by Mr. Fothergill.—Yours, very truly, JOHN HEYWOOD.

MR. ROGERSON believed that generally speaking the Fothergill process was the most sensitive, but this quality depended on the amount of washing, the quality of the collodion (which notwithstanding the improvement in its manufacture of late, still varied greatly in its properties, scarcely two samples from the same maker ever being found uniform), and also the condition of the bath. He believed one cause of failure was the general practice of using so small a quantity of the bath solution, that after a very few plates were sensitised the strength became greatly lowered, and after two or three doctorings it was impossible to know without making an analysis what the strength or condition of the bath was. He used a bath that contained £5 worth of nitrate of silver, and when made correctly to begin with, he could use it for a very long time with uniform results; it was nearly neutral, and when it became necessary to use any acid he added nitric in preference to acetic.

Mr. WARDLEY gave the preference to Taupenot, though he believed Fothergill was superior in sensitiveness, and also in keeping qualities: the former, however, was not so very decided as to constitute any important advantage; the latter he attributed to the layer of albumen, which acted as a sort of varnish to protect the sensitive surface from atmospheric influences. His great objection to the Fothergill process lay in the great difficulty in preparing the plates, more particularly large ones, so as to be free from markings. He regarded it as next to impossible to wash with so small a quantity of water as to leave the free nitrate of silver in a state of even dilution all over the plate; and if recourse was had instead to a weak silver bath, he fancied the same result would be produced, as the plunging or rocking motion caused the water to act with a wave-like force more on the centre than the sides of the plate. The great advantage in the Taupenot process was the ease and certainty of its preparation. He agreed with Mr. Draffin that the quality of the collodion and condition of the bath might vary within very wide limits without producing any marked influence, whilst no injury could be done with any amount of washing, and the film would bear even rough usage. Great objection was raised to the liability of the film to blister: this, no doubt, was a serious drawback, and in many instances could not be obviated; but much might be done by exercising care in preparing the plates in a dry atmosphere, and drying them before the fire after coating with albumen. In the print taken from the negative sent by Mr. Draffin, and which was developed at the last meeting, he thought the blisters might have been so far removed as to prevent them affecting the print, if they had been rubbed with a little cotton wool and water, taking care not to make the plate too damp.

Mr. WHAITE thought that the new modification proposed by Mr. Lloyd, of flushing the plate with a very diluted albumen after sensitising, tended very much to prevent markings.

The conversation subsequently embraced a variety of subjects, chiefly relating to practical details, in which many members joined. Mr. Wardley produced a print of the white marble statue of the Queen, in Peel Park, to illustrate his assertion at the last meeting, that feeble skies were no proof of over-exposure. The principal object in the picture gave a brighter reflection than the sky, and though by no means over-exposed, the sky had printed through considerably. He mentioned, also, that he had treated some plates that had inadvertently become exposed to the light with a solution of iodide in alcohol, and after dipping again in the nitrate bath the plates were restored to their original sensitive condition.

The CHAIRMAN then announced, that in accordance with a resolution lately passed, the next meeting would not take place until the 14th of September; and he hoped the interval would be productive of successful results, and that the experience gained at these meetings would now be found of practical utility.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE members of this Society held their last meeting for the present session on Tuesday evening, the 31st ult., at the Odd Fellows' Hall. WILLIAM HOWELL, Esq., one of the Vice-presidents, occupied the chair, and there was a numerous attendance, several ladies being present.

After the usual preliminary business had been disposed of, a letter of apology was read from the Rev. William Law, who, unable to be present on account of illness, sent the promised paper, and requested either the secretary or the treasurer to read it to the meeting.

The treasurer, Mr. OSBORN, said that no one more than himself regretted the absence of the reverend gentleman, as the paper would lack much of its interest from its being unaccompanied by the genial manner and manipulative skill of the author; but as he (Mr. Osborn) had had considerable experience in Dr. Hill Norris's dry process, he would venture, at the conclusion of the paper, to occupy a short time with some details of his own experience.

Mr. Osborn then proceeded to read Mr. Law's interesting paper upon *Dry Processes and their Difficulties.* [See page 147].

Mr. OSBORN said that amateur photographers, as a rule, were too much given to change; they could not take up a process and deliberately work it out. He pleaded guilty to this charge himself, but thought he had been tolerably faithful to the dry collodion process of Dr. Hill Norris, having practised it for two years, and being now able to produce by it results quite equal to the wet collodion in detail and half-tone. The principal drawback, as necessarily it must be with all dry processes, was a want of sensibility, and if this could be overcome, he had no doubt Dr. Norris's process would take the lead as a dry process. Fothergill's method was correct in principle, and hence the good results which had been obtained. If, therefore, the final washing off the excess of the preservative solution were applied to Dr. Norris's method of preparing plates, they would get from fifteen to twenty per cent. of increased sensibility. On Saturday morning last he (Mr. Osborn) took an excellent negative in a bright light—exposed two seconds, Ross's stereo lens four-and-a-half inch focus—quite as full of detail as any dry plate he ever saw. In his opinion the Doctor's plates were more easily prepared than Fothergill's, because their preparation could be reduced to this simple expression, namely, cleaning plates, coating with collodion, sensitising, thorough washing with plenty of water poured on gently from a jug, coating with the gelatine solution, which may be used cold, and when properly made will keep any length of time; and finally washing until all greasiness disappears: the exposure, say two minutes to Fothergill's one minute, which latter statement was, he (Mr. Osborn) thought questionable, as he never saw a good Fothergill with less exposure than two-and-a-half or three minutes. As for the developement, he could develop Norris's plates in from five to seven minutes, while he was told that the Fothergill plates took from one to three or four hours occasionally. This was a manifest advantage. For cleaning glass plates quickly he could safely recommend Solomon's diamond polish, which he had used with great success and increasing pleasure.

After some discussion on one or two points noticed in the paper, the best thanks of the meeting were given to the Rev. Wm. Law for his interesting communication.

Mr. MORRIS, with a few appropriate observations, then introduced Mr. Woodward, of Baltimore, United States, to the meeting. This gentleman is the inventor of the solar camera, now extensively used in America.

Mr. WOODWARD said that before exhibiting the prints he had brought with him, he would remark that the instrument he had invented, and which was exhibited before the Society last year, did not appear to be perfectly understood in this country. The solar camera, as its name implied, was an adaptation of the principle of the solar microscope to the ordinary camera, for the purpose of obtaining a light sufficiently strong to be used for enlarging small photographs. He (Mr. Woodward) was an artist by profession, and it had often occurred to him that if he could get sufficiently enlarged copies of ordinary photographs, to paint over on canvas, it would be a great assistance to him. Following up the idea, he had at last succeeded in producing the invention then before them. One advantage to which he would call attention was, that it was not at all necessary to have a dense negative for the purpose of enlarging, as a positive answered admirably, thus enabling them to take instantaneous portraits, as, for instance, of children, and afterwards enlarge them to any size. Another advantage was that there was no spherical aberration about the image. They knew of course that the use of a diaphragm in the lens tube was to flatten the image; he (Mr. Woodward) had accomplished this by placing the condenser in such a position that the point where the rays of light crossed should answer to the diaphragm ordinarily used. By this means he had no loss of light, and at the same time got the image free, or nearly so, from spherical aberration. Another advantage of the solar camera was, that the pictures might be printed direct upon the sensitive paper, thus avoiding the necessity of making a second negative, or of developing a paper picture. He generally used the ammonio-nitrate paper, and sometimes albumenised paper.

Mr. WOODWARD here exhibited a number of very large pictures, enlarged from mostly half-inch negatives, and excited the wonder of the members by exhibiting a life-size half-length portrait. Amongst other specimens were an instantaneous portrait of a child, enlarged to about sixteen inches by twelve inches; a copy of a map, about two feet six inches by twenty inches; several very large portraits and landscapes; and one landscape about forty inches by thirty inches, all of these being sharp and clear to the edges, and free from any apparent distortion or spherical aberration. The map showed a little curvature, arising from a portrait combination having been used for the original negative.

Mr. WOODWARD said the power of the instrument had been put to a very severe test by the United States coast survey. It was desired to ascertain how far it would be practicable to enlarge small copies of maps to scale, and for this purpose a sheet of paper was prepared with geometrical squares crossed by diagonal lines. A collodion positive was taken of this, and projected, magnified eighty times, on a screen covering one hundred square feet. The image was found, on accurate measurement, to be geometrically correct, the lines, &c., being all free from curvature to the edge.

In reply to a question,

Mr. WOODWARD said that the life-size picture took forty-five minutes in the printing.

Mr. JOHNSTONE wished to know how the correction of the error of curvature could be accounted for, because theoretically there ought to be a great amount of curvature.

Mr. WOODWARD replied that he was not able to enter fully into the theoretical argument; he could only point to the pictures exhibited as a practical overcoming of the difficulty.

A discussion respecting the application of the principle then took place, in which Messrs. Howell, Ball, Morris, Osborn, Whitlock, and others took part, and to which Mr. Woodward courteously replied, giving much information, suggesting, amongst other things, that it was better in taking pictures for the purpose to work under the full power of the lens used, thus taking half or quarter plate pictures with a full plate lens, &c.

The thanks of the meeting were then cordially given to Mr. Woodward, and the meeting adjourned until August.

It is understood that the instrument is likely to be extensively used in Birmingham, several of the largest operators having signified their intention of purchasing. It was considered by the meeting destined to create quite a new era in photographic portraiture. The astonishing size of the pictures exhibited, all of them pure untouched photographs, seemed to take every one by surprise.

Exhibition.

THE EXHIBITION OF THE FRENCH PHOTOGRAPHIC SOCIETY.

IN order that our readers may possess a perfectly unbiassed account of the important exhibition of photographs, now on view at the "Palais des Champs Elysées," at Paris, we have, in addition to our usual Paris correspondent, retained the services of an *English* gentleman at present on the spot, so that, besides our ordinary source of information, we are enabled to obtain and give an account of the display from an *English* point of view. We have a word or two to say by way of preface, to guard against future misconception. Our correspondent, besides being a photographer, is a very ardent admirer of works of art generally, and consequently we find him laying more stress than we should personally do on the success of those following that branch of our art which the French happily term *re-production*—an important branch no doubt—but one that, in our own opinion, ranks far below photography from nature, whether in landscape, portraiture, or *genre* subjects. The following is therefore the account

FROM OUR SPECIAL CORRESPONDENT—

Paris, 1st June, 1859.

The Third Exhibition of the French Photographic Society is alike remarkable over its predecessors for the excellency of its habitation and for the general superiority of the works exposed.

This year it is, with the authorisation of the Minister of State and the imperial director of the fine arts, held in a part of what was, in 1855, Le Palais de l'Industrie, but as it is now called Le Palais des Champs Elysées; and its extent will be readily understood by the English visitors who remember the space in the south gallery occupied by the productions of Prussia, Baden, Bavaria, and Germany, the entrance being by the beautiful staircases in the south-west pavilion, and which are so large and extensive as to provide for the rapid entrance or exit, free from any danger, of an immense multitude—indeed, on one occasion, 15,000 people leisurely retired from this palace in eight to ten minutes, a feat not to be accomplished at any public building in London. On one side of these pavilions, approached from corridors of three to four yards wide, are retiring rooms, lavatories, &c., for ladies; and on the reverse side the same accommodation for gentlemen —while for light, ventilation, convenience and beauty, the whole edifice may be taken as a model for English architects to start from. On the exterior of the palace upon the frieze to the ground story, and which runs all round the building, are carved in large letters and gilt the names of men of all times and countries, celebrated in the arts, sciences, philosophy, &c.; and it is singular that it should so happen, that the first name on the frieze to the entrance to this Exposition is that of Daguerre.

The Society invited all photographers, French and strangers, to forward works which would be submitted to the examination of a jury consisting of amateurs and professional men, charged to decide on their admission or rejection, whose names were published at the time when the general invitation was given, and which were communicated by your Paris correspondent. This was a guarantee of good faith on the part of the Society, that a proper supervision would be exercised in the selection of works to be exposed; and it is understood that the censors have had occasion to put their veto upon some of the works forwarded by French artists, but not on any from England. Rumour says, that of the works rejected was one by Bilordeau, a large portrait of a person in the act of cutting his corns; and although the focussing was probably sharper than the knife used on the occasion, this could not save the contribution of corn-cutting from being returned to its author, and who has since reaped on its account a considerable quantity of "chaff." The like authority informs us that the frame of visiting cards representing the portraits of a branch of the imperial family, which are really so unsatisfactory as photographs, only rode out the storm of condemnation raised by the jury, and anchored safely in the space allotted to Disderi and Co., through motives of deference to august personages so misrepresented.

The space allotted to the Society is arranged into a number of courts, by partitions under three yards in height — the first four have for centres, the square balustraded areas which partly light and ventilate the ground floor of the palace under the galleries. These balustrades support a continuous narrow table, which runs round each area, and upon which are placed stereoscopes of all shapes and fashions, and were a great attraction to visitors, who examined with interest the many slides laid upon the tables; but especially the American stereoscope, which by the simple turning of a revolving knob by either hand, while the eyes of the beholder are placed at the lenses, exposes successively several dozen of views. The appearance of these stereoscopes is very good, being suitable for the drawing-room. The four sides of the courts have narrow counters, which serve as elbow rests, and for making minutes in the catalogues, while the visitor is examining leisurely the photographs hung above to the upright screens, and which is a very convenient arrangement, the entrance from court to court being at each corner. The contributions from England, Belgium, Russia, and Germany, are hung to the ordinary upright screens without the counters in front. The covering of the whole of the screens and tables is of a glazed dark sea-green coarse calico, and forms a good background for the various tones of the photographs, and which are, generally speaking, very well lighted, the roof over this gallery, of iron and glass, being at an altitude of upwards of ten yards.

The contributions of those artists who have sent only a few works are not sufficiently separated from each other, and it takes some trouble to discover whose they are. This might have been easily obviated by a coloured cord or ribbon nailed on the screen, and surrounding the frames of each contributor, so that one could see at a glance where each exhibitor's works began and finished, especially if the name and address of the exposant had been fixed on the upper part of the space occupied by his works, in lieu of as now being wafered on to the middle frame, the other proofs being without name or easily distinguished mark — of course, with some of the principal exposants (such as Bingham), who occupy the whole side of a court, this uncertainty does not exist; and in others, their names are stuck on every proof, offensively enough, and too much in the advertising style. The French universally make a mess in the printing of English names and places, and here we find described the respected partner of Mr. Maull as "Folybanc," exposant, from Londres. Robinson, of Leamington, is re christened as "Monsieur Henri," but our friends understand well the advantage of resting the eye when fatigued with examining works of art, and know that it requires some relief when wearied, so that it may regain its pristine force to appreciate every nicety of form and colour — this is provided for by two bays of the colonnade next the nave being left open, so that the visitor may let the vision rove over the beautifully arranged garden occupying the whole of the nave, in which are arranged, with charming taste, the floral contributions to the show of the Horticultural Society, and the statuary forming part of the Exposition des Beaux Arts; the whole making up a very agreeable picture of winding walks, beds of flowers and plants, rustic stepping stones across a running stream, spanned by a picturesque wooden bridge, fountain, undulating grass-plats, a view the *tout ensemble* of which is rarely to be seen.

The arrangement of French catalogues does not give much assistance in systematically reviewing a miscellaneous exhibition—the general plan being to take as a basis the alphabetical arrangement of exposants' names, their works being numbered consecutively in the catalogue, while the hanging is altogether independent of the numbering, thus: — the first, Mr. A., is hung — the second on the list of A's is in probably quite another part of the exhibition, and one must have a considerable knowledge of an exhibition before he can proceed to follow any plan for reviewing the same, and more so for the purposes of study. Take the catalogue of the exhibition of pictures by living artists now open at Paris, where the alphabetical arrangement of exposants' names is followed: you find No. 1; probably 380 will be the next picture hung to it; and No. 2, the work of the same artist as No. 1, will be in another saloon, and cannot be found except by searching every room till it be discovered; for there is not the least indication in the catalogue where a picture is hung. This is a source of great inconvenience and loss of time. I think the catalogue of the Royal Academy is worthy of imitation here, for in it it is clearly stated No. 1 begins over the door of the first room, and the pictures are numbered following each other in the places they occupy all round the room. You then go into the next room, commencing over the door, and so on to the last. Then, at the end of the catalogue is an index of the exhibitors and the numbers of their works, so that if you want to examine, seriatim, the labours of one painter, you turn to the index and take the numbers attached to his name, and turning to the catalogue, the number gives you the room in which it is hung, so that you can easily go from one to the other. I name this more fully, so that next year the hint may be taken and acted upon, the advantage being evident.

I calculate, from the catalogue, the following statistics, which show the relative favour the various processes enjoy: the totals are only approximate because several exposants do not describe the processes by which their works were produced:—

Wet collodion	700	Collodion on paper, dry	9
Dry collodion	26	Waxed paper	200
Taupenot	55	Waxed cloth	17
Collodio-albumen	10	Waxed turpentined paper	1
Preserved collodion	1	Paper, wet and dry	43
Collodion and honey, dry	4	Albumen	8

With positives fixed without hypo'; positives by the process of M. Charles Nègre; gravure heliographique; and photo-chromie, by Testud de Beauregard, give us a variety, though not always charming. *(To be continued.)*

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER III. *(Continued.)*

UPON COLOUR.

"If we place a bright red wafer upon a sheet of white paper, and fix the eye steadily upon a mark in the centre of it, then if we turn the eye upon the white paper, we shall see a circular spot of *bluish green* light of the same size as the wafer." * * * "If we make the preceding experiment with differently coloured wafers,

we shall obtain ocular spectra, whose colours vary with the colour of the wafer employed, as in the following table :—

Colour of the Wafer.	Accidental Colour.
Red	Bluish green.
Orange	Blue.
Yellow	Indigo.*
Green	Violet reddish.†
Blue	Orange red.
Indigo	Do. yellow.
Violet	Yellow green.
Black	White.
White	Black."

Sir David also adds —"As in acoustics, where every fundamental sound is actually accompanied with its harmonic sound, so in the impressions of light, the sensation of one colour is accompanied by a weaker sensation of its accidental or harmonic colour. * * * * The term *harmonic* has been applied to accidental colours, because the primitive and its accidental colour harmonise with each other in painting."

The student will now perceive that the mixture of two primary colours in due proportions produces that hue which is complementary to the colour remaining, as blue and yellow forming green produce the complementary of red, red and yellow that of blue, blue and red that of yellow. If you place green beside red, each colour contributes additional brilliancy to the other, the green imparting its accidental or complementary red, and the red is green. The same may be said of both the primaries, and all the various hues obtained by combination, every hue and colour being capable of receiving fresh power, by being placed near the hue or colour which is its complementary.

In practice this principle should never be lost sight of: it may be applied with varied results according to circumstances, viz.—if the red should not be the primary or pure red, the complementary colour also varies, becoming more blue if the red approach orange, and more yellow if the red be purplish, &c.

RULES OF ART FOUNDED ON SCIENCE.

Every healthily organised eye recognises the effect of colour, and is susceptible of pleasant sensations from its harmonious arrangment; hence arise those rules and principles existing in the works of all our greatest and most of our early masters, which have since received confirmation from the discoveries of modern science; and although a new and eccentric school of painting has achieved some notoriety, by setting such rules and principles at defiance, truths based upon the experience of great men who were practical illustrators of the precepts they taught, which have been adopted by generations of critics, and proved by the evidence of scientific facts, must eventually triumph over the eccentricities of those whose morbid cravings for novelty and originality could find no better outlet.

I trust the reader will not therefore listen to any who would rob that grandly powerful and supremely beautiful "language of the light colour," of its noblest attributes and most effective uses. Learn to look upon this portion of your art as a glorious field for the intellectual battles of an earnest art-interest — to see it stretching before you full of smiling promises, calling up the memory of its illustrious conquerors, and fraught with the hopes of yet unconquered realms. Landscape and historical painters can, of course, march farthest into the realms of this beautiful world of colour, but there are no lack of laurels within the grasp of even photographic colourists.

CONTRAST.

Sir David Brewster states, that "when the eye has been strongly impressed with any particular species of coloured light, and when in this state it looks at a sheet of white paper, the paper does not appear to it white, or of the colour with which the eye was impressed, but of a different colour, which is said to be the accidental colour of that with which the eye was impressed." From this fact arises the necessity of studying colours, not only in reference to their individual intensity and power, but also in reference to their effect in combination. For instance, the *accidental* or *complementary* colour of red being green, if I place red beside another colour, the latter receives therefrom sufficient green to mar or increase its intensity, character, and beauty, according to its nature. The celebrated M. Chevreul's work on colours ‡ contains an anecdote in point.

"A few years ago," says the author, "the proprietor of one of the first manufactories in Paris, wishing to print grey patterns upon grounds of apple green and of rose, refused to believe that his colour preparer had given any *grey* to the printer, because the designs printed on these grounds appeared coloured with the complementaries of the colour of the ground."

The grey appeared green on the rose ground, and rose upon the green ground, and doubtless caused no little annoyance and perplexity.

Sir David Brewster details so clearly his experiments and their results, that I cannot do better than again quote from his work on optics.

To describe the colours already named more fully, red is the most powerful, yellow the most luminous, and blue the most retiring (these three colours are termed *pure*). Orange is warm and advancing, partaking of qualities belonging to its components; green, mean and weak in itself, is nevertheless soothing and kindly in its effect, and of great practical use in heightening and contrasting other colours or hues; and purple, sombre in its near relation to shade, is yet of great utility and beauty; citrine bears the same relation to the other two tertiaries, russet and olive, in its degree, as yellow to the other primaries; russet (partaking largely of red) claims its due proportion of that colour's qualities, while olive is the humbler representative of blue and green.

Descending yet lower in the scale, we pass through the various browns into the neutral tints ending in that which represents the absence of all light, and consequently colour *black*.

Every *colour* has its *scale*, graduating in strength, until it is lost in white upon the one side, and in black upon the other; the one half being composed of its *tints*, and the other of its *shades*, the use of white forming the first, and the addition of black the last — *hues* or compounded colours obey the same law.

RESUME.

I have now endeavoured to show that, strictly speaking, we have but three *colours*, namely, red, blue, and yellow — that the mixture of these in various proportions form *hues* — that the addition of light, or its representative, among pigments, white, creates *tints*, and the addition of black, *shades* — that shades and tints form *scales* — that colours are warm and cold, advance and retire — that some are allied to light, others to darkness — that some excite and others soothe, &c. — the importance of contrasting colours with each other, because both give and receive thereby fresh beauty or power. In reiterating these principles I wish to impress them firmly on the mind.

Independently of absolute contrast of colour, attention must also be directed to the effects produced by contrasts of intensity; black bestowing its complementary *white*, gives and receives intensity; all hues partaking therefore of black receive in proportion the force bestowed by their complementaries. If you place in juxtaposition a strip of black and another of white cardboard, where the white joins the black it will appear lighter than parts more removed from its influence, and where the black touches the white, it will appear darkest. It follows, therefore, that colours contrasted with white appear deeper at the point of contact, and others contrasted with black will for the same reason appear lighter. Too strong a contrast of intensity, like too violent a contrast of colour, should however be avoided, such contrasts appealing to the skill and genius of the painter for their most harmonious results.

Besides the harmonies of contrast and intensity we have what is sometimes termed the harmony of analogy, produced by the various tones and hues of a single scale, or of the colours and hues placed in the order in which they are found in the solar spectrum. The further application of these principles will be illustrated during our progress through the more practical portion of my instructions.

(To be continued.)

Letters to a Young Photographer.

No. XII.

MY DEAR EUSEBIUS,

Conceit is a weakness to which photographers are by no means subject: in fact, I think they are *ex officio* exempt from it. I do not remember that I ever encountered a conceited photographer in my life. It is true that some are prone to indulge in the free use of superlatives and expletives when speaking of their own productions, but that is only a pardonable vanity, very admissible in newly-fledged photographers. They take it as babies take the measles, and with careful nursing they get safe through it. As a general rule, the worthy craft of photographers, to which you and I have the honour to belong, are too modest by half, which

* Or the cold purple which indigo in the pigment appears.
† Painters say red.
‡ A work I very strongly recommend.

I think a pity, for no man gets through life successfully who is too modest. *Brass*, my dear Eusebius, is the true philosopher's stone of the nineteenth century: it has the wondrous power of transmuting ignorance and impudence into gold—pure, bright, gold.

I do not think *you* at all conceited when you tell me you have succeeded in getting the best picture you ever saw—no, not conceited at all! Of course you are the best judge (of your own productions), and think you know a good picture from a bad one, when you see it. But somehow or other it happens that the first tolerably good picture a young photographer gets is always "the best he ever saw." Of course, my dear Eusebius, we old boys who know what is what, do not take this expression quite literally, we generally make a discount of about ninety per cent. off these early blossoms, and then we come pretty near the mark. But you want my opinion of your picture? What do I think of it? I suppose you expect me to be candid, and to use no soft-sawder. So this is what I think. Your picture is very fair for a green hand, but not so good as to encourage you to hope you will become entitled to the gold medal prize at the next exhibition. But lest you should feel disappointment, and become disheartened in not obtaining the reward you doubtless consider your due, I will magnanimously present you with a first-rate washed *meersham* (I bought it in the street for a penny), accompanied with four ounces of the best 'cuaster, as a token of my high esteem and appreciation of your embryo skill, and your untiring patience and assiduity. Continue in the course you have so auspiciously commenced, and if wind and tide favour your onward course, who knows but some fine day you may be appointed photographer-in-chief to the sable King of Dahomy!

You have now to learn how to take positives upon glass, or *direct* positives, as they are called. Such pictures have many points of resemblance to Daguerreotypes. They present a very similar appearance. They are not multiplied by printing, like negative *clichés*; but they satisfy the wants of the public for a cheap picture, taken and delivered while the customer waits; and, in a commercial point of view, they are the most profitable to the artist. The larger portion of the photographic business is carried on in positives, which are offered, in certain cases of rivalry, "at the small charge of threepence, case included."

You doubtless understand that a positive is a picture to be viewed by reflected light; that is, you do not look *through* it but *on* it; consequently, the light and shade must be in their natural places, and not reversed, as in the negative. The manipulations vary somewhat from those employed in the negative process. You require a different kind of collodion, you expose less in the camera, and you employ another developing agent.

Doubtless, in your efforts to obtain negatives, you have occasionally produced positives, rather dingy-looking, perhaps, but still such as will have given you an idea of what they are like. The effect might have been very much heightened if you had poured over your picture a quantity of a saturated solution of bichloride of mercury; the picture would have become white all over, and when washed with water, and afterwards treated with hypo. as usual, you would have got a brilliant positive, which, when backed with black varnish or leather, would have shown you one of the protean forms of our black art.

Collodion for positives is required to be much thinner or weaker than for negatives. Some operators prefer iodising it with iodide of ammonium. Some say that any old collodion will do, provided it be diluted with alcohol and ether. The following formula yields a very good positive collodion:—

Ether	20 ounces.
Gun cotton	1 drachm.
Alcohol	20 ounces.
Iodide of potassium	1 drachm.

This collodion contains about half the usual quantity of gun cotton and iodide in negative collodion; so you arrive at the same result by diluting negative collodion with alcohol and ether until the film on the glass takes a blue tint in the nitrate bath. The exposure in the camera will be about half that required for a negative.

It is of the utmost importance that the glass plates be scrupulously clean, as the least speck of dirt or film on the glass shows as a defect in the picture when developed. The light portions of the picture are formed of a deposit of bright metallic silver, the shadows are the transparent glass, through which the dark backing is visible. It is therefore very evident, if any foreign matter adheres to the glass plate, it must become very palpable to the sight upon the most cursory examination.

You must make a new nitrate of silver bath for your positives: it requires to be of less strength than that for negatives; and also to be acidulated with nitric acid, as follows:—

Nitrate of silver (crystallised)	5 drachms.
Water	12½ ounces.
Nitric acid	2 or 3 drops.

There must be a certain relation between the strength of the collodion and the strength of the nitrate bath. This it is scarcely possible to determine, except by direct experiment. Sensitiveness of the film and intensity of the image are the points of consideration, and will influence your proceedings when you have arrived at the point of understanding the chemical philosophy of photography.

You require to be particular in the selection of the nitrate of silver with which you make your bath. I recommend the pure crystallised, because it is safe. Fused nitrate is apt to contain a basic nitrite of silver, and give an intense, misty, solarised picture.

The developer for positives that yields the best results is sulphate of iron. Pyrogallic acid gives a dull yellowish picture, which is quite repulsive, unless nitric acid be substituted for acetic acid, then the image is very white, but looks chalky or opaque: here is a formula if you wish to try it:—

Pyrogallic acid	1 grain.
Water	1 ounce.
Acetic acid	20 minims.
Alcohol	50 minims.

You will develope with sulphate of iron: the best formula is that of Messrs. Davanne and Joüet, being that which produces the purest whites:—

Water	12½ ounces.
Alcohol	5 drachms.
Acetic acid	5 drachms.
Sulphate of protoxide of iron, in crystals	4 drachms.
Sulphuric acid (by weight)	1 drachm.
or by measure, 0·58 drachm.	

The proof developes rapidly; therefore, I should counsel you to employ, at first, a vertical or horizontal bath for this solution, so that the development may take place uniformly all over the proof.

When developed, wash the plate freely with clean water and fix with cyanide of potassium, of the strength of one per cent. Place the proof over a black ground, and if it has been well executed a brilliant picture will be apparent.

You can also fix with hypo.; but then it is necessary that the proof be thoroughly washed from the developer, otherwise, if any acid remains, it will decompose the hypo. and cause the picture to be veiled, or become black or grey, through the formation of sulphide of silver.

When dry, the proof may be varnished in the usual way, and afterwards covered with a black varnish, which you make as follows:—

Rectified turpentine	12 ounces.
Powdered bitumen	2½ ounces.
White wax	½ ounce.
Lamp black	1 to 2 drachms.

Cover the picture by means of a soft brush, and when nearly dry, apply a piece of paper to the varnish, to protect it from scratches.

Photographic Glossary.

Nitrate of Ammonia—A salt formed by the combination of nitric acid with ammoniacal gas. It is in the form of prismatic crystals. It is deliquescent in the atmosphere, and dissolves in rather more than its own weight of water. Nitrate of ammonia is a solvent of oxide of silver, but it is not often employed in photography.

Nitrate of Baryta—A salt composed of nitric acid and oxide of barium; permanent in the atmosphere; dissolving in twelve parts of cold and in four parts of boiling water. It is used in photography to obtain proto-nitrate of iron, by decomposing with it a solution of protosulphate of iron.

Nitrate of Cadmium—A deliquescent salt formed by the union of nitric acid with oxide of cadmium. When collodion is iodised with iodide of cadmium, nitrate of cadmium is formed in the sensitising bath, which some operators consider is apt to injure the sensitiveness of the film and induce *fogging*.

Nitrate of Copper—A salt formed by the combination of nitric acid and oxide of copper. It forms crystals of a splendid blue colour, very soluble in water. This salt is very caustic,

corroding the skin; its taste is insupportably styptic. It ap- appears in some formula for developing collodion negatives, in conjunction with pyrogallic and tartaric acid, and is said to make the image appear as quickly as sulphate of iron.

Nitrate of Iron—There are two nitrates of iron: the nitrate of the protoxide and the nitrate of the peroxide. The first, usually called the proto-nitrate, is in emerald green crystals; it is readily obtained in solution by adding a solution of nitrate of baryta to a solution of proto-sulphate of iron. It is a deoxidising agent, and is employed as a developer for collodion positives.

Nitrate of Lead—A white anhydrous salt consisting of nitric acid and oxide of lead; soluble in eight parts of water. It is sometimes substituted for nitrate of baryta in preparing the developer for positives; it is also added to gallic acid to enhance its developing properties.

Nitrate of Magnesia—A salt once in great repute for its application as a preservative agent in the collodion process; its deliquescent properties kept the collodion in a moist state. It has been superseded by glycerine, honey, meta-gelatine, &c.

Nitrate of Potass—Nitre, saltpetre. This well-known substance is used in the preparation of pyroxyline. When sulphuric acid is poured upon it decomposition ensues, and the nitric acid, in combination with the potass, is liberated.

Nitrate of Silver—One of the most important salts employed in photography. It consists of nitric acid in combination with oxide of silver; crystallising in large, flat, six-sided plates. It appears also in commerce as *fused*, taking the form of the mould. It is soluble in about its own weight of water, and almost insoluble in cold alcohol. In moist air it slightly deliquesces. The solution of this salt is quite colourless, and it is not affected by light unless organic matter be present with it.

Nitrate of Uranium—A salt which has lately become very familiar in photography, through the experiments of Mr. Burnett and M. Nièpce de St. Victor. There are two nitrates of uranium, the proto-nitrate and the pernitrate; the latter is the one employed; it is a nitrate of the sesquioxide of uranium. It crystallises in the form of yellow prisms, which effloresce in the atmosphere, and are very soluble in water, alcohol, and ether. It is sensitive to the action of the chemical rays of light, and is employed in positive printing.

Nitrate of Zinc—A compound of nitric acid and oxide of zinc. It is a deliquescent salt, and has been proposed for preserving collodion plates, in the same manner as nitrate of magnesia, and with the like success. It is also added to the developing solution formed of gallic acid, as a partial substitute for acetic acid.

Nitrate of Silver Bath—The solutions of nitrate of silver employed for sensitising collodion plates, and for exciting positive paper, are usually termed "nitrate baths." The formulæ for these several baths are given in all treatises on photography.

Nitric Acid—This acid is composed of five atoms of oxygen and one atom of nitrogen, combined with one atom of water; it is then called monohydrated nitric acid. At ordinary temperatures it is liquid, colourless, fuming in the air, and very corrosive. It serves to prepare all the nitrates, as described above, and mixed with hydrochloric acid, it forms *aqua regia*, a solvent for gold. In a concentrated state nitric acid does not act upon silver, tin, or copper; the addition of water is required to furnish oxygen to the metal. When the metal is oxidised, the nitric acid attacks the oxide and converts it into a nitrate.

Foreign Correspondence.

Paris, June 10th, 1859.

You must not expect much from me, except belligerent photography, until the war is over. Our art is fairly enlisted, and we must be content to accept its war-offerings which may throw some new light on the resources and appliances of heliography. M.M. Bisson Frères are now busily engaged upon a very interesting subject. Sometime ago, the Austrian government published a very beautiful elaborate map of the Lombard-Venetian kingdom, the capital of which is now occupied by the Allies. Previous to the war this map was sold to whoever wished to buy it; but it has since been withdrawn from circulation. One of our map-publishers happened to possess a copy of this map, now become so interesting and valuable, and also greatly in request. To re-engrave it would have been out of the question; so photography, with its *hey! presto!* despatch, was called in to do the work of supplying copies. The map was so large that it became necessary to divide it into several portions to meet the resources of the camera. The task of copying these several portions, so as to unite again into one harmonious whole, was one of very great difficulty; but it has been admirably overcome by M.M. Bisson. The reproduction is perfect—the name of every place, every contour, which demanded so much time and labour from the engraver, is brought out in the twinkling of an eye. Great are the triumphs of photography!

M. Chevallier has made a very ingenious and useful application of photography to topographic surveying. The details are too extensive to come within the limits of a letter. He calls his apparatus the photographic plane-table: it consists of a solid tripod of ordinary wood, around the axis of which the camera is made to traverse, so that the *objective* can be presented to any part of the horizon desired. The collodioned or albumened glass-plate is circular, and is held in a concentric frame of the same form, the periphery of which is furnished with teeth, like a cog-wheel. The frame and glass-plate can also turn around a common axis which passes above the photographic image, so that the latter can be projected entirely upon the lower part of the plate, and be limited laterally by two systems of shutters, either by two verticals brought as near to each other as possible, or by two perpendiculars, concurrent with the centre of the plate, and embracing an angle as sharp as can be desired.

From these arrangements it happens that, without removing the plate from the interior of the camera, we can, by turning it on its axis, present it to various parts of the horizon in succession, thus obtaining sectional pictures which, when united, form a complete panorama of the locality.

There are, of course, many minor details necessary to secure perfect integrity of the angles, &c., which belong more to the engineer than to the photographer. The invention has been examined by Professor Benoit, who has reported favourably upon it to the Society for the Encouragement of Arts.

Mr. Young's interesting experiment of developing negatives in daylight has led to new investigations on the nature of the composition of the photographic image. M. Davanne announced his theory, which was as follows:—That the image appeared, not because the developing agent continued the reduction begun in the iodide of silver, but because the developer in contact with the nitrate set the molecules of silver free, and these latter fixed themselves upon those parts which the light had influenced. For, in fact, neither gallic nor pyrogallic acids, nor protoxide of iron alone, ever developed an image formed solely of iodide of silver. If the image appeared, it was because the iodide was mixed with a greater or lesser quantity of nitrate.

The part the developer plays is then *not* that of transforming an invisible sub-iodide of silver into visible metallic silver, as suggested by M. Leon Kraft.

The negative photographic image is produced, not by the reduction of the sub-iodide, but by a metallic deposit. To be convinced of this, it is only necessary to test the quantity of silver contained in the sensitive coating before the developement of the proof and after developement. It will be found that, upon an image completely developed, *even after fixing*, which removes all the excess of iodide, there is a quantity of silver greater than the whole of the iodide of silver contained in the sensitive layer before developement: there is then a deposit, and the photographic image appears because the molecules of silver deposit themselves upon the sensitive coating.

This deposit is due to a molecular attraction, the first molecule of silver being set free, the others group themselves around it, and attach themselves to it—just like what takes place in the formation of crystals.

But from whence comes the first molecule of reduced silver? The light has determined either the formation of a sub-iodide of silver, or the reduction of a part of the iodide of silver into metallic silver. In both cases the quantity of iodide modified is so small that it escapes the microscope (?), but the reactions which develop the image will prove that a modification has taken place. Doubtless there may be admitted, first, the formation of a sub-iodide of silver, by the luminous agency—then the decomposition of the sub-iodide into metallic silver, either by hyposulphite of soda, or by developing agents; but the image remains none the less invisible, and will only appear by the addition of nitrate of silver. As the sub-iodide must be decomposed, why complicate the ques-

tion by the presence of this useless sub-iodide at all, the existence of which is more than doubtful, as it has never been isolated, and is even not mentioned in our works on chemistry, when it is evident, both for the iodide of silver, as well as the chloride, that the prolonged action of light yields metallic silver? It seems much simpler to say that a luminous action, insufficiently prolonged, gives only a feeble quantity of metallic silver. Besides, it must be admitted that the sub-iodide of silver, or the intermediate body attackable, before as well as after the hyposulphite of soda, by warm diluted nitric acid, comports itself with reagents in the same manner as metallic silver; then, if it possesses the same properties, it must be one and the same substance.

To sum up what appears to be the explanation of the constitution of an image, the simplest view seems to be that which is in harmony with chemical reactions and photographic experience, and may be stated as follows:—

Light sets free some molecules of silver, in greater or lesser number, according to its intensity, these molecules are the first points of attraction.

The developing agents develop the image in so far as, mixed with nitrate of silver, they can set at liberty new molecules in much greater number, which proportionably group themselves around the principal nucleus points, and cause the image to appear with a rapidity that always increases in proportion as the centre of attraction becomes greater.

I shall be glad to see if, among your photographic philosophers, there is one who will give a better theory of the formation of the photographic negative image than the above. J. P.

Correspondence.

"THE GLYCERINE PROCESS" IN PHOTOGRAPHY.

To the Editor.

Sir,—In the last number of the *Journal of the Photographic Society* a paper is published which was read on the 10th ultimo to the Photographic Society of Scotland, *On a useful application of Glycerine in the Collodion Process*, by Mr. T. Rodger, of St. Andrew's.

Now, without any desire to claim your aid for the purpose of asserting our priority of publication, we ask leave to mention the following facts:—

A process identical with that of Mr. Rodger's paper, and used with exactly a similar object, was one among certain others that, in our hands, had for some time stood the test of actual work.

Deeming it, for reasons hereafter given, of some value, we published it, and other photographic improvements and propositions, in a pamphlet dated the 31st of March last. We may add that both before and since we have advertised this pamphlet in your paper, as at the command of any one who would send us three stamps, and that by such means it has been largely circulated.

Setting aside, however, our claim to priority of use and publication, we confess—assuming Mr. Rodger's paper to have been written without his being aware of our experiments—that we are much gratified to find that it confirms the value of the glycerine process. Supported, therefore, by this testimony, we would invite the attention of photographers, through your columns, to try the "plan for deferring the fixing of negatives," which we give from the pamphlet above mentioned, page 12:—

"After the application of any of the ordinary developers, and the usual washing—a small quantity of water being sufficient for this—coat the negative with *glycerine and water* mixed in equal proportions (pouring off the excess in the ordinary way), and put it carefully into the plate box. It can then be fixed after returning home, the next day, or indeed within any reasonable time; all that is required being, in the first place, to wash off the glycerine, and this it will be found can be done very readily.

"Nor is it necessary to obtain by the developement in the field the whole intensity the negative is capable of giving. Generally, in using the iron salts, sufficient is accomplished if all the required details of the picture appear; any degree of intensity can be got by using the formula given below, which was published by Mr. Shadbolt, in *The Photographic Journal*:—

"'Fix with hypo-sulphate of soda, wash well with common water, drain slightly, and then wash with a few ounces of distilled water, again drain, and pour on a solution in the proportions of—

Pyrogallic acid	2 grains.
Citric acid	1 grain.
Distilled water	1 ounce.

to which add about 20 drops of pure solution of nitrate of silver (about 30 grains to the ounce), but not that previously used for baths or any other purpose. Finally wash well: no more fixing will be required.'"

A few words in explanation, and we will trespass no further on your space. It is admitted that an important step would be gained if the means of working the ordinary wet process were rendered portable, convenient, and simple. This is chiefly our aim, it was the object of our glycerine experiments, and it was with the view of calling attention to the results at which we had arrived, that our pamphlet was published.—We are, yours, &c. MURRAY & HEATH.

43, *Piccadilly, W.*, 8*th June*, 1859.

[We have received the preceding since writing the remarks in our leader of the present number. The pamphlet alluded to we have had before us some time, intending to notice it, as one containing many very useful hints to amateurs and others. Want of space, from pressure of other matter, has alone prevented our doing so earlier.—Ed.]

MODIFIED META-GELATINE PROCESS.

To the Editor.

Sir,—The addition of *phosphate of soda* to the metagelatine solution, in the proportion of about one grain to the ounce, seems greatly to increase the sensitiveness, but not more so than a chloride of same base.

Should you think the above worth any thing, you are welcome to do what you like with it.—I am, yours, &c. D. W. HILL.

May 31, 1859.

POSITIVES ON OPAL GLASS.

To the Editor.

Sir,—The proceedings of our Society at the last meeting will clearly show that photographers, either professional or amateur, have nothing to fear from the use of opal glass, in consequence of any patent. This article is admirably adapted for photographs and portraits. The peculiar advantage of using opal glass is, that you have the picture as perfect by reflected as you have by transmitted light. I have tried to produce this effect by the ordinary process but have not succeeded. The following gives me all I can desire, and therefore I lay it before your readers with confidence. I herewith send you a specimen.

I may here remark, that a negative possessing fine detail is the best for this purpose, but there is no actual necessity it should be so.

1st. Dissolve pyroxyline in equal quantities of ether and alcohol, add chloride of ammonium to saturation. Allow this to stand for a night, and then it is fit for use.

2nd. Upon a well-cleaned piece of opal glass, previously coated with dilute albumen, and dried, pour this solution, as is customary with ordinary collodion, and sensitise in a forty grain neutral bath of nitrate of silver.

3rd. Drain, and then pour upon it a solution of gelatine, ten grains to the ounce, and five grains of honey. Allow it to dry either spontaneously or before a fire.

4th. Print upon this by superposition, as on the ordinary albumenised paper, until you see the edges slightly bronzed.

5th. Remove from the pressure frame, wash, colour slightly with gold, say half a grain to the ounce in distilled water, finish with solution of hyposulphite of soda, wash well, dry and varnish.

I may here state, that it is not imperative to use a pressure frame, as I use a board covered with a piece of black cloth, thus completely avoiding the risk of breakage.—I am, yours, &c. J. A. FORREST.

Liverpool, June, 1859.

[Notwithstanding your careful packing, the stereograph is broken in two pieces. The opal glass is, however, evidently capable of producing charming effects. For portraits the effect is very pleasing; the second sample sent arrived in perfect condition. It has all the beauty of a painting on porcelain.—Ed.]

ANHYDROUS ALCOHOL.

To the Editor.

Sir,—As the opportunity for a bit of photographic gossip with you occurs but seldom, I am induced to take advantage of a leisure hour, and make an observation or two on some of the contents of your late Journals, which I always read with much interest.

When Mr. Mayall read his paper on collodion, was there no chemist present to tell him that his method of preparing anhydrous alcohol could only be partially successful if one of the ingredients happened to be in excess? Both chloride of calcium and carbonate of potassa rapidly absorb water; but the salts which result from their mutual decomposition —chloride of potassium and carbonate of lime—have no such property. Mr. Mayall's formulæ altogether seem to show a prediliction for *mixtures*.

An old friend of mine, the late J. T. Cooper, who used to make use of anhydrous alcohol in chemical analyses, once gave me the following directions as a good practical method of preparing it:—

"Procure some lime fresh from the kiln, and sprinkle enough water on it to make it fall into powder. Fill a covered crucible with the powder, and submit it to a red heat. Transfer this powder, when cold, into a bottle containing strong spirit of wine, and shake it frequently for several days. Then immerse the bottle in a water bath, connect the neck of it with a condensing worm, and draw off the alcohol, setting aside the first half as *absolute*."

The object of slacking the lime was to get it in fine powder; the subsequent heating being sufficient to drive off the water but not to agglutinate the particles into a hard lump.

My friend used a carboy, and operated on two gallons at a time.

Yours very truly, GEO. JACKSON.

EXCELSIOR! EXCELSIOR!!

To the EDITOR.

SIR,—The trumpet of the great Goliath of the Fothergill process has again been sounded through the medium of your pages, but its sound is weak and shrill, rather resembling that blown from a "penny whistle:" its discordant notes jarring with the general harmony.

Now, Sir, at the risk of bringing down obloquy and contempt upon my head, for presuming to give an opinion upon a subject which would seem to be the exclusive right of one only, I maintain that I have a claim to do so for the following reasons, viz.—Because I consider it a subject in which every photographer is interested; because I am an ardent lover of the art, and have made dry processes my study for the last three years; because I think that a good dry process is essential to the future progress of the art; because there seems at present a number of conflicting opinions respecting this process; and because I am an amateur, and am not making this an advertising medium, not being interested in the sale of a "special collodion" or varnish, or other photographic material.

I admire the frank and disinterested manner in which many of our distinguished photographers give the results of their experience to the public; yea, even printed pamphlets of instructions, gratis;—what generosity! what beneficence!! although I for one have always been too modest to accept favours of this description.

But to return to the process "*which gives results equal to any wet, and superior to all other dry processes;*" would that I could endorse the sentiment. It is not my object to prove that as good results cannot be obtained by this as by any other dry process. The collodio-albumen and Fothergill's being the only two in which I have had experience, I have practised the latter in its various modifications since its discovery, and after many alternate successes and failures, I have arrived at this conclusion:—

That it is very much less sensitive than collodio-albumen.

That nothing like absolute certainty can be depended on.

That the path to success and to disappointment being so nearly alike, it is impossible to say upon which we have been treading until we meet the ghastly image of failure face to face, by the dim light of the operating room.

Since the season for out-door operations commenced, I have practised the process very extensively, principally in copying. My lens is a "Ross's Petzval," for plates 10 by 8, focus $13\frac{1}{2}$ inches, and I use a $\frac{3}{4}$-inch stop. I never think of giving less exposure than sixteen to twenty minutes, and even thirty minutes, if the light is not very good. My failings have been principally from *under* exposure. I have used various samples of collodion, but with no improvement as to sensitiveness. However this may differ from the published statements of some of its votaries, such is the process as I work it; but here I may be met with the question—Do I use the "*collodion specially prepared and peculiarly adapted for this process?*" "*That pronounced by the most eminent photographers more sensitive than, and superior to all others.*" Let me also be asked—Do I take Holloway's pills? and the same answer will do for both, and for the same reasons—I may say that I have seen it used, with very poor results. Probably my want of success may be from not having obtained the pamphlet; but I rather incline to Mr. Lloyd's mode of manipulating, which does not require a volume of printed instructions to work it. I have no doubt but Mr. Lloyd can appreciate the favour he has received in being allowed the credit for *publishing*. The discovery it appears was made long before he (Mr. L.) thought of it. What presumption not to have waited till it had been published officially, for then we might have had also *a special albumen,* superior to all others for flushing purposes!

The object I have in writing this letter will be attained if, when we are next favoured with any remarks upon the process which is to eclipse every other, this may be added as a testimonial from Yorkshire, in addition to those from Cheshire and Gloucestershire. If desired I have no doubt but I could procure several others in this town, and would humbly suggest that the following recognised form should be used:—"Sir,—Having heard of your far-famed collodion for the Fothergill process, and the rage it was causing in the country, I caught the epidemic, and determined to obtain a quantity, and am happy to say I was cured with one bottle!"

I am, yours, &c. J. H.

Bradford, June 7, 1859.

[In the preceding communication our correspondent makes an indirect charge against us personally, viz.—that of permitting our columns to be used unfairly as the medium for advertising. This, to the best of our knowledge and belief, we have never done. We have allowed full latitude to all for discussion of matters of interest; even personalties when directed against ourself we have permitted to appear, but against others we cannot allow them to pass without remonstrance.

Mr. Keene as a *photographer* has a right to be allowed to express his opinions, even supposing them to be biassed by self-interest: he attaches his name to his communications; our readers can place their own estimate upon these opinions, and we are always ready to admit fair rejoinders—witness the present letter. As a *dealer in collodion* Mr. Keene *advertises legitimately* in all or many of the publications devoted to the literature of photography. Now, has our friend J. H. in the above letter treated Mr. Keene quite fairly by mixing up statements made in the latter's *communication* with those in his advertisements?

We have used Mr. Keene's collodion, and found it good, as also that of many other makers, including Horne & Thornthwaite's, Ponting's, Thomas's, Hardwich's, &c., &c., and although all have their special qualities, we have been able to produce good results by the Fothergill process *with the whole of them.* We do *not* work, however, according to the directions given by Mr. Keene, nor anybody else exactly, but incline rather, like J. H., towards Mr. Lloyd's method of manipulating. We may remark, *en passant*, that when we wish to try any particular collodion, we as a rule purchase it without the maker's knowing anything about it. We do not approve of the sneers against printed pamphlets of instructions *gratis*, given by dealers in photographic chemicals. There is no *false pretence* about the matter at all: the object is a commercial one, and is recognised as such. Many of these little *brochures* do contain useful hints and instructions, and, when they do so, we never hesitate to notice them favourably; any more than we hesitate to condemn and expose false assumptions, when we detect them.

We are obliged to J. H. for the statement of his experience and opinions:—such are highly useful. We trust, however, that he will be more forbearing in future, and not unnecessarily impute bad motives where errors of judgment are probably the only faults.—ED.]

THE PATENT OUTRAGE.

To the EDITOR.

SIR,—I received, to-day, the *Journal of the Photographic Society*, and, after reading the leader, on turning over, I came to "Specification of patent granted to Oliver Sarony, of Scarborough," &c. Now, what do you say to it? Will that patentee stop me from doing what I think fit with my negatives, and what *I*, perhaps, have invented, or at least carried out, and as the catalogue of our exhibition will prove, was the first who exhibited positives composed from several negatives. I think the first were in 1854, or certainly 1855. Besides, you recollect my paper, read some time ago; and I can *show*, that years ago, I transferred a good head on to a bad body; so also a good body with a bad head (portrait of an unruly child). Of course he must have paid for his patent, and it serves him right. That is one punishment.

I am, yours, &c. O. G. REJLANDER.

[For our opinion upon this matter we refer to a more prominent place in the current number.—ED.]

ANSWERS TO CORRESPONDENTS.

MARY ANNE.—Many ladies are photographers, and good ones too. Commence with a stereoscopic camera. We advise you, however, to beg, borrow, or purchase a good negative, and learn to print well first of all. It is a capital plan to get your hand in, and assists you in the principles of photography far more than most people fancy.

WALLIS.—The greasy appearance of your plate is due to the ether and alcohol not having been entirely displaced from the collodion. You must leave it a longer time in the bath; about three or four minutes is generally enough, but if not, give more. Should it appear greasy on taking it out, put it back again for another minute or so, and continue thus until it comes out quite free from the fault.

WALTER PURDAY.—We cannot publish an opinion upon the relative value of lenses made by the various opticians; even if it were possible to form a just opinion, it would not be fair to do so; but we have several times indicated the way to test lenses. All makers who can produce very high class objectives must have some better and some worse than others. It is absolutely impossible to get all equally good, unless some be brought down in quality.

GOLD TONING.—Dissolve your gold in aqua-regia, as you propose; the silver and copper must be removed, or they would act injuriously. To effect this, add solution of *common washing soda* (carbonate of soda), until all effervescence ceases, and litmus paper is no longer reddened, when a green cloudy precipitate of carbonate of copper will be formed. This takes some hours to settle: pour off the *clear* gold solution, and filter the remainder. A solution of double chloride of gold and sodium remains, which, however, requires the addition of a single drop of hydrochloric acid to prevent the precipitation of metallic gold. It is then fit for use.

J. M. M. (Moffat).—We will reply more at length in our next; we have not room in the present number. Your pictures appear a little under exposed, and under developed also, but the fault you complain of is not due to these causes, though a little aggravated thereby. Old collodion that has lost much of its ether by frequent use is very apt to produce the fault you describe: remedy, add a little ether. New collodion, with cadmium iodiser, especially if more than usually charged with alcohol, is liable to the same: remedy, add a few drops of chloroform, say ten, to each ounce of collodion, and shake up well, till the pyroxyline, which is precipitated, is redissolved. Let your film set well before immersion in the nitrate bath.

RECEIVED.—"W. Ackland," "C. J. Burnett," "F. J. Cox."

THE PHOTOGRAPHIC JOURNAL.

No. 97, Vol. VI.—JULY 1, 1859.

The property inherent in films containing albumen, when associated with certain salts of silver, of retaining, permanently, the actinic force communicated by exposure to light, so as to admit of the development of an image even after the removal of the sensitive coating—a property first brought under the notice of photographers by Mr. Young, of Manchester—is one that has naturally fixed the attention of many of the scientific section amongst our brethren. It is not at all surprising that a very considerable difference of opinion appears to exist relative to the explanation of the phenomenon, and we are induced to advert to the subject because a gentleman of note amongst the photographic community—one who is deservedly regarded as an authority in the chemical department especially—has put forth an opinion that appears to us impossible to establish as founded upon a correct hypothesis.

The gentleman to whom we allude is M. Davanne, a careful investigator and an earnest photographer.

The opinion to which we take exception is, that the action of the light reduces to a metallic form a very minute portion of the silver compound, which is not removed by the hyposulphite of soda subsequently applied, and which serves as a nucleus, about which the visible image is afterwards deposited from a solution of nitrate of silver supplied for the purpose.

We are not about to advocate the theory of the sub-iodide, also put forth on the other side, by way of explanation, because we think there is evidence to show that *both* theories are erroneous.

We have very carefully examined, under the microscope, films of the nature above mentioned, that have been affected in certain parts by actinic influence so as to become impressed with a developable image, but without being able to detect even the smallest amount of difference between the impressed and unimpressed portion of it. For this purpose we have employed a microscope of the highest class, and powers varying from fifty to one thousand diameters. Moreover, we have illuminated the objects with ordinary and also with polarised light, and to show that our manipulation is not likely to be in fault, we may mention that we have been familiarly acquainted with microscopical science for something like a quarter of a century.

Metallic silver is a solid opaque substance, it is totally unknown in a transparent condition, and the assertion that it can be deposited in particles so minute as to escape detection by the microscope, when properly applied, appears to us to rest upon *pure assumption*, without the possibility of proof in the present state of our knowledge. But this is not all, for while we have no experience that should lead us to accept such an assumption as founded even upon probability, the experience we possess would lead us to a diametrically opposite conclusion. The actual measureable space appreciable by a microscope like the one we employed is so excessively minute, that, if we name it, the probability is that the general reader would either disbelieve or not comprehend it; nevertheless, we will give an instance, by way of example, of an actually ascertained fact. The siliceous cuticle of a minute vegetable organism, known as the pleurosigma macrum, is adorned with numerous transverse and longitudinal striæ, the transverse ones being at the distance of the eighty-five thousandth part of an inch from one another. As compared with this, the most minute and impalpable powder grains are awkward lumps.

We are thoroughly convinced that silver, in a metallic state, because of its opacity, could not escape microscopic detection, and, for a similar reason, that a sub-iodide would also be perceptible, as if transparent or semi-transparent, its refractive power differing from that of the atmosphere would, by certain manipulations known to skilled microscopists, readily be made available to demonstrate its presence.

About a couple of years back, while presiding at a meeting of the Microscopical Society, the best method of producing a convenient Finder being under discussion, a suggestion was made by Mr. Maltwood that microscopists should avail themselves of the aid of photography for the purpose; not merely a crude suggestion, but backed up by the actual production of a specimen. We at once perceived the practicability of the plan, and though there were some minor points of detail to be worked out so as to ensure uniformity of construction, these were simply matters of mechanical skill.

Messrs. Smith & Beck, the eminent microscope makers, have now brought the articles in question into the market, and, as there are some points about the apparatus, of interest to photographers who are not microscopists, we shall, probably in our next, give a description of it and explanation of its use.

It will be seen from a letter from Mr. Spencer, published amongst our correspondence, that, relative to the presence of oxalic acid in some samples of collodion, the conjecture of Mr. Hardwich is probably the right one, as it does not appear that the compound is found unless the collodion "bottoms" are from such as has been "iodised." This accords very closely with experiments made previously in a similar direction by Mr. Hadow, who produced, under analagous conditions, oxalate and saccharate of potash in considerable quantities.

Crystal Palace Art Union.—Among the photographic works which subscribers of one guinea will be enabled to select are—a view of the Miner's Bridge, North Wales, 18 × 14 inches; five views of the Crystal Palace, 10 × 8 inches; nine views of the Fine Art Courts of the Crystal Palace, 10 × 8 inches; a series of twenty stereoscopic views of the Crystal Palace and Park, a series of twenty stereoscopic views of the most attractive features of the Crystal Palace, and one copy of a series of large photographic views of the interior and exterior of the Crystal Palace, 24 × 18 inches. Subscribers of three guineas have the option of selecting a photograph of the interior of the Crystal Palace, 54 × 24 inches.

Photography in the Picture Galleries.—Some time since very fine photographic copies of the Cartoons at Hampton Court were made, and have been exhibited at various places, to the gratification of admiring connoisseurs. The Marquis of Hertford is following the example thus set, and is having photographs made of his noble collection of pictures. It is to be hoped the other large collectors throughout the country will pursue a similar course, and, by bringing the gems of art which adorn the galleries of our land within the reach of those who cannot make the pilgrimage of those artistic shrines, elevate the taste and refine the feelings of the masses of our population.

PHOTOGRAPHIC CONTRIBUTIONS TO ART.

The man who produces a pleasing picture, accessible to many admirers, is a general benefactor, and deserves, at the least, a kindly thought from all who participate in the fruit of his brain.

There is perhaps no one subject upon which more difference of opinion exists than the definition of what constitutes Art in its widest and most elevated sense, and this in some measure accounts for the assertion so frequently made, that true art is not appreciated by the many. Is it not more than probable that such a statement is due rather to the erroneous definition of art by its would-be expounders than to any real foundation in fact? It is contended by some that no one can understand art-productions who has not undergone a course of training for the purpose, and that consequently for one unlearned in the world of painting to pronounce an authoritative opinion upon a picture is sheer presumption.

As in many other matters there is here some truth mixed up with a considerable amount of error. Like all other gifts a keen perception of the beautiful can be cultivated to an extent undreamt of by some, although it *is* a gift after all, and there is no means of communicating it where it is not already existent; but the power of conceiving beauty, and then of giving expression to it, is a very different thing from, and far more rare than, the mere apprehension of beauty.

Art and beauty are more or less interchangable terms, for beauty consists, not solely in form, or colour, or number, or expression, or sentiment, but in a happy combination of all or some of these elements. And what is this but Art? We take it then that true art is a thing rather to be *felt* than understood, and though he who *understands* must of necessity feel it, many may feel, and feel deeply too, who do not, in the common acceptation of the term, understand.

That which is beautiful in the abstract must excite some pleasing emotion of the mind; and though the introduction of excitants of unpleasing ideas may be quite legitimate, such is only the case when they serve to heighten the effect of others which elevate and refine the mind, just as in music the sweetness of concords is enhanced by the judicious use of contrasting discords.

If then a work of pictorial art be truly meritorious, we contend that as a rule it can be *felt* and *appreciated* by the many, more especially and in a higher degree when attention is drawn to the various points of excellence by those whose perceptive faculties for the beautiful have been cultivated; but, and here is the test, if the points indicated be not readily admitted as excellent by most men, then in all probability the critic has set up for himself a false standard that does not conduce to a true verdict.

We do not mean to assert that what is generally admired must of necessity be good or beautiful: ideas on this head are apt to be governed much by comparison; but when defects are pointed out, they can generally be readily enough perceived, and so also with beauties. Not many men are discoverers, but most men can perceive if shown to them what has been discovered by others.

We had no intention, when commencing this article, of being led away into so long a digression; we were about to express our approbation and admiration of a recent production of Mr. O. G. Rejlander's that we *feel* to be truly beautiful — and yet the subject is nothing but an old man, and poor as well as old. Moreover, he is performing an act that we have heard painters say never can be made a graceful one, that of satisfying the cravings of hunger.

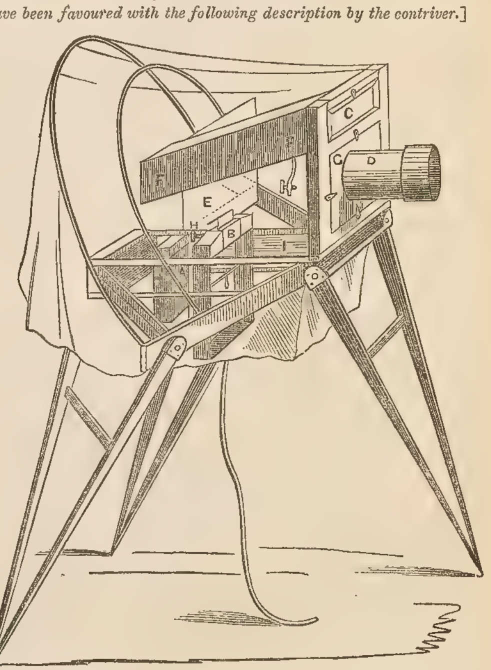
The title of the picture, for a picture it is in the best acceptation of the word, is *The Wayfarer*. An old agricultural labourer, clad in the homely smock frock and gaiters, is seated on a bank by the wayside; beside him are his bundle, with his stick thrust through the knot of the old handkerchief, which ties up his pack, and his hat cast aside to allow the gentle summer breeze to cool his heated brow. In his right hand is an open clasp knife, with which he has cut the morsel that he is in the act of placing between his lips from a lump of bread and cheese held in his left hand, resting on his knee, with the piece of old newspaper in which it had been previously wrapped. Nothing can well be more commonplace than is indicated by the foregoing description; in what then can its charm consist? Not only that the figure is well posed, the photograph well executed, with a total absence of conventionality, and the whole truthful to nature, but the *sentiment expressed is one of gratification* — rest to the weary, refreshment, repose. The attitude is natural and by no means devoid of a certain kind of grace; the composition harmonious, the masses of light and shade well balanced, the background in perfect keeping with the figure, yet unobstrusive, as it should be; and although there is all the beauty of detail for which photographs are unsurpassable, breadth of effect is not in any way sacrificed.

Every wrinkle in the face of the old man is perceptible, every vein and sinew of the hands, every fold, nay almost every thread of the well-worn garments can be made out, and even the very texture of the materials of which the latter are made; yet for all that there is nothing of the pre-Raphaelite cast about the composition. Mr. Rejlander is a thorough *artist* as well as a skilful photographer, and though all of his works bear the impress of thought, and are evidently executed with a settled purpose, in that now before us he has been pre-eminently successful. There is no "sham" about it at all. It is an every-day subject truthfully depicted, but not in an every-day manner. Mr. Rejlander is in fact a Rembrandt amongst photographers; and such productions as the one we have been endeavouring but poorly to describe we cannot but regard as we have already designated — True Contributions to Art.

PHOTOGRAPHIC CAMERA AND DARK TENT COMBINED.

By Wm. Moginie.

[*We have been favoured with the following description by the contriver.*]



The above apparatus is constructed with a view of enabling photographers to work the wet collodion process in the open air and away from home, without requiring a darkened room, and without allowing the plates to become dry between the times of coating, exposure in the camera, and development.

It differs from the usual apparatus employed for the purpose, inasmuch as the whole of the process is conducted in *one* enclosed space, instead of using a camera and a tent, thus reducing the bulk of a travelling apparatus at least one-half, and dispensing altogether with one tripod-stand.*

When erected it measures two feet six inches in height, two feet ten inches in width, and one foot ten inches in length.

Sufficient light is admitted to allow the operator to coat a plate, place it in the silver bath A, expose it to the action of the lens, and develop the picture without any intervening medium between himself and the plate on which he is at work—the light being shut off *only* at the window C, during the time of exposing the plate.

Pictures can be taken with combination, single, or stereoscopic lenses of any range of focus, from three inches to sixteen inches, by altering the position of the frame B, in the open space I.

The lens D, can be placed in four different positions by means of a moving front G; but it remains stationary while focussing an object, the plate-holder B, itself having the necessary adjustments attached to it. A coarse adjustment, to be used according to the focus of the lens and the distance of the object from the apparatus, and a fine adjustment H (which takes the place of the ordinary rack and pinion of a lens), is used to secure the surface of the plate being always in perfect focus; both are worked from the inside of the apparatus with the greatest ease and certainty, focussing more correctly than with ordinary ground-glass contained in the usual frames.

The plate can be placed in any desired position by a movement answering the purpose of an inclining back, and capable of being used in seven different directions, namely, above and below the lens, even with it, forward, backward, to the right, and to the left. Frames and shutters are not required, thus avoiding many difficulties often experienced by photographers, such for instance as finding the plates too large or too small for the inner carriers; or, as is frequently the case, a shutter becoming so fixed that it cannot be raised.

This apparatus will produce a picture on a plate of any size that can be admitted into the bath, and need not necessarily be square. Dippers also are done away with: the plates are cut half an inch longer than the depth of the bath, which admits of their being placed at once in the nitrate of silver solution when coated with collodion; and the picture having been taken on the lower portion of the plate (inverted when exposed), the extra piece of glass can be broken off and the plate transferred to the plate box, a cut having been *previously* made with a diamond, to allow of its thus being reduced to the usual size; therefore, the whole process can, with moderate care, be carried out from beginning to end without the chemicals once touching the fingers, a great boon to those who wish to keep their hands free from stains, cyanide, &c.

A supply of water is contained in the cistern F, sufficient to effectually wash a dozen plates, and it is provided with a flexible tube and small tap.

The focussing-glass E, is firmly held in its place by a strong spring and it is moved horizontally with the upper portion of the frame B, by means of the fine screw H. The prepared plate occupying exactly the same position when the ground-glass is removed, must of necessity be in perfect focus.

Not the least recommendation in its favour is its portability, the whole, when packed in its case, measuring only thirteen inches in length, by four and a-half inches in width, and eight inches in depth. The chemicals, lens, bath, plates, and a supply of water are placed in another case about the same size; both are provided with straps, and may be carried, one in each hand, with the greatest ease for a considerable distance. The stand, which is exceedingly firm, is a folding one, and is carried at the back like a quiver for arrows, with a strap over the shoulder; it is twenty-five inches long and six inches wide, by one and a-half inches.

The whole is peculiarly adapted for tourists' use, especially while travelling on the continent, where weight and bulk are great obstacles in the path of English photographers. The case containing the apparatus weighs, when complete, eight lbs.; the second case, containing the lens, chemicals, bath, and plates, &c., eight lbs.; and the stand and etceteras make the total twenty-four lbs. Pictures have been taken with it equal to those taken with ordinary cameras, and with these advantages:—The plate is coated, excited, exposed, developed, washed, and fixed in any part of the country where the apparatus can be set up.

By some further modification, the total weight can be reduced to twenty lbs., an alteration intended to be carried out.

* It is therefore dependent upon the same principle as that adopted by the late F. Scott Archer, who used his camera as his tent, Mr. Moginie employing his tent as a camera.—Ed.

SILVER PRINTING PROCESSES.

Including Salting, Sensitising, Toning, Fixing, and Testing Baths.

By C. J. Burnett.

(Continued from page 107.)

In the papers now described, in which silver oxide is precipitated and retained in an insoluble or approximately insoluble form by the tartaric, oxalic, succinic, fumaric, citric, or other oxygen acid, it is perfectly possible, without destroying the paper and perhaps even with benefit to its keeping after sensitising, to wash out the free nitrate and the soluble products of decomposition. In this case, however, the proportion of organic salt should perhaps be increased, and a weaker silver bath (say 20—30 grs. to the oz.), in order to diminish loss of silver, employed; or we might make the first washing out be with water containing a little of the vegetable salt, so as to precipitate on the paper the silver contained in the adhering silver nitrate, instead of washing it away. This will be further recurred to in my promised formulæ for negative processes on paper, albumen, and collodions, containing the vegetable and other insoluble salts of silver-oxide.

C.

The Washing immediately before Toning.

I find a solution of common salt much recommended and used. As, however, I have often, in my experiments, found this to have a tendency to produce redness, I have (except where this redness is wished for in order to *balance against* the blueness of a very thorough gold toning or *protection*) recommended plain water, or first plain water and then an exceedingly weak ammonia water; or, if something farther is wished, a trial of a little tartrate, or oxalate, or carbonate of potash in the water. I also have made some experiments in the addition of common salt to the alkaline bath to be described.

D.

Toning Bath with Gold Salts.

Convinced from the first of the error involved in the addition of hydrochloric acid to our ordinary gold bath, and that the move ought rather to be in the opposite direction, it is now* about two years since I recommended to my friends here the use of an alkaline gold bath; the ground of my recommendation being, that the salt of gold commonly employed is a *ter*chloride, containing, as its name implies, three atoms of chlorine to one of gold, and that, consequently, in using a bath of it (chloride of silver consisting of *equal* atoms of silver and chlorine), for every atom of gold deposited on the print three atoms of silver are lost to the print by being converted into chloride, necessitating thereby a large amount of over-printing and waste much better avoided, and the evil being of course still further increased if we add acid; while by calling in the aid of an alkali or its carbonate (present in the bath either as carbonate or partly in the state of an alkaline aurate, or in combination with auric oxide acting as an acid), we remove or diminish greatly this waste, and enable the exchange of the two metals to be conducted on something like terms of fair reciprocity. For my statement of its existing in this form I have, I believe, good chemical authority to back me.

The alkali which I have chiefly recommended here has been common washing soda, as the most accessible, or the bicarbonate. Ammonia having the material disadvantage, except where a *very* large excess of acid or chloride of ammonia is present, of being apt to precipitate most of the gold, I have not recommended it, except (and for trial only) to those who will insist on working with a gold salt prepared with muriate of ammonia and nitric acid, or nitrate of ammonia and muriatic acid.†

As to the quantity of alkali to be employed, what I have recommended has been—first, to make a *strong* ordinary plain terchloride of gold bath, and then, having also made a saturated solution of common soda, to add to the gold bath, stirring all the while, first as much of the soda solution as was necessary to make it turn red litmus paper to a blue, and use the bath for toning thus, or as nearly as possible neutral, or else—say as much more of it again, or yet more, especially if intended for toning albumenised papers to

* I have no wish to raise any doubt as to what I see stated as to Mr. Waterhouse having independently made use of an alkaline bath; and I am even perfectly willing to admit his priority, if he employed it or recommended it before the summer or spring of 1857. As to the addition of the citrate to the gold bath, that we owe entirely to that accomplished chemist Mr. Hardwich; for though I tried and recommended some of the vegetable salts in platinum and palladium baths, my recommendation of vegetable salts (in spite of some trials of the formiates, &c., as additions to Sir J. Herschel's ferric, and in my own analogous, uranic, chrysotypes and palladeotypes), did not extend to the gold salts.

† Instead of with the pure terchloride, or, if they must have a double salt, with one prepared by dissolving the gold in a mixture of nitric acid with either common salt or bromide of potassium.

increase the penetrative power:—the quantity of the soda solution being easily estimated if we pour it out of a common graduated fluid measure without any weighing.*

Platinum Toning-Baths.

To the use of the bichloride of platinum, there would appear to be constitutionally the following objections (some of them more or less extending to other platinic salts):—

1. The same difficulty alluded to in the case of the gold-terchloride as to relative proportions, not so great an extent, atomically, from the platinum salts being only a *bi*chloride, or containing only two atoms of chlorine to one of metal; but augmented again, in another way, to an extent possibly more than enough to overbalance this constitutional difference, by the fact of the atomic weight of platinum being less (not more) than that of silver and only one-half of that of gold; while the difference of specific gravity will tell still further in the same direction, by diminishing the *space* occupied by, and consequently the pictorial value of, each atom of platinum deposited.

2. That the platinum in the bichloride (or chloroplatinic acid) has a much greater affinity for, and is consequently much less easily reduced from its combination with, the chlorine than is the gold in the terchloride of gold.

3. The great tendency of the bichloride of platinum (or chloroplatinic acid—a far more stable and more powerful acid than the auro-chloric) to form an insoluble double salt, containing both silver and platinum. This conduces apparently both to the weakening of the picture and to loss of platinum, by its deposition as an insoluble yellow salt, in combination with the silver in the lights.

4. The tendency to form an insoluble double salt with potassium, &c., pointing out the chloride of potassium as the *least* suitable, and that of sodium as the most suitable chloride for the salting of papers intended for platinum-toning. There is however in our toning with platinum, or with any other metal, another and most important consideration which must not be overlooked. This is the relative amount of light or of darkness which is reflected by equal bulks or surfaces of the different metals (or of their oxides or other compounds, as deposited on our picture). The probable inequality in the pictorial value of even equal bulks or surfaces, renders the chemical deductions insufficient guides, and leaves the whole question of the relative advantages of the different toning-metals (or even of different salts or differently made baths of the same metal), both considered as to the amount to which the picture is likely to be weakened or strengthened by each of them, and as to the pecuniary expense of each of them, a question on which practical experience, and a thorough trial of each, must give the decision.

I give a few formulæ for platinum toning-baths.

No. 1.

Using the common bichloride, add to it, as to the terchloride of gold, a solution of soda, or carbonate of soda, and use it thus, or rather with the farther addition of tartarate, acetate, or formiate of soda (or one of their acids), exact quantity immaterial; or we may add the vegetable salt first, and the carbonate of soda afterwards, heating, if we please, to promote formation of platin*ous* oxide. Precipitate of an insoluble platinate is sometimes troublesome here. Would potash answer better?

As to the strength of the bath, every one must please himself. Suppose a much larger quantity of platinum than of gold necessary, bichloride of platinum costs only 24s. or less per ounce.

No. 2.

A bath containing pure platinic sulphate or nitrate,—these salts having the advantage over the bichloride of having equal atoms of acid and base.

The formiate, tartarate, and acetate, &c., of platinum have advantages over these in ready reducibility; but the same cause interfering with their long preservation, the best mode of employing them is—

No. 3.

Make your bath with a solution of platinic sulphate† or nitrate, and then add to it a solution of tartarate, formiate, or acetate of soda or other deoxidiser, and use the bath either without, or after, a heating, which tends to reduce the platinic to a platinous or less stable oxide. A bath of the vegetable salt of platinum might of course be prepared directly by a solution of the oxide in the formic, acetic, or other acid.

Nos. 4, 5.

Similar baths to Nos. 2 and 3, but with No. 4, platin*ous sulphate* or nitrate, or No. 5, platinous tartarate, formiate, acetate, oxalate, or citrate, substituted for the corresponding platin*ic* salts. The platinous salts are more easily reduced than the platinic, and are preparable also directly by solution of platinous oxide in the respective acids. I have more and important particulars respecting the platinous salts for another paper.

Besides the salts now recommended in these formulæ, I may name the ethylochloride of platinum alone, or with soda or potash, and the fluoplatinate of potassium. Also, (proto) chloride of platinum, or dissolved in soda or potash solutions.

I have not yet got the *pure separate* platinates and aurates tried, but they do deserve trial as toners, the metal being easily reduced from them by many deoxidisers. I have also tried salts of palladium, iridium, and rhodium, in toning-baths, but without apparently any distinctly valuable results.

(To be continued.)

* We fear a bath prepared thus would be very apt to form a precipitate of reduced gold, if kept for any time.—Ed.

† Platinic sulphate is not at present a regular article of commerce. It may be made by heating the bichloride with sulphuric acid; but for the ordinary photographer, no great chemist, nor possessed of much variety of chemical appliances, and with the materials commonly accessible, the following is the best formula:—Dissolve say ¼ oz. of bichloride of platinum (value 6s.), in ½ oz. of water, add to it a saturated solution of potash as long as a precipitate is produced, when this ceases let it subside thoroughly, and pour off the liquid which is sulphate of platinic oxide, and will keep good for any time.

N.B.—The precipitate contains about two-thirds of the platinum, and must be kept for its after extraction, which is quite easy. The acetate, tartarate, formiate, and oxalate may be made directly in precisely the same way, but dont keep so well, so that it is better to use the sulphate, with vegetable salts added.

PHOTOGRAPHY AT THE HANDEL FESTIVAL.

The recent Festival has proved a wonderful success — musically, financially, and pictorially. The photographic art was well represented by Messrs. Negretti and Zambra, photographers to the Crystal Palace Company. While the representatives of the "fourth estate" were actively employed in making their "pen-and-ink sketches" of the beautiful prospect which met their gaze, and recording the vivid impressions made by the orchestral marvels which greeted their ear, *our* art representatives were busy in the production of wondrous pictures which, in a few moments, conveyed to those present, and subsequently to a distant public, truthful representations of the picturesque scenes which met the eye of the visitor to the Crystal Palace during each day of the great Handel Festival.

The orchestra was photographed on the day of the rehearsal, and it was printed, mounted, and posted on the orchestra before the commencement of the second part of the concert. The orchestra was again taken on Wednesday; and on Friday, owing to the different arrangement of the ladies, which gave the orchestra a prettier appearance, it was once more photographed. With reference to the success as a photograph, we may, without fear of contradiction, state that, taking into consideration the oiled waterproof yellow awning over the orchestra, it is a wonderful picture, containing, as it does, some three thousand distinct portraits. Besides the orchestra, there were a number of negatives taken on each day of the festival of all the persons occupying the centre transept: so that we have a collection of some 20,000 portraits. We fear, however, these pictures may cause some mischief; for some gentleman who had *very* important business in London may, perhaps, be seen seated very cosily with some fair one that may make his absent partner not at all pleased with the gentleman's trip to London.

On Friday a stereoscopic picture of the Royal Box was taken, printed, mounted, and presented by Mr. Negretti to H.R.H. the Prince Consort previous to the commencement of the second part. When it is considered that the box was constructed, as usual, with the everlasting covering of red cloth; that H.R.H., as a lover of music, cannot refrain from beating time; and that there was an awning all over the transept — this picture was eminently successful; again, when we consider that the usual time of exposure under ordinary circumstances in the palace is about ten times more than that of any ordinary glass room — a quarter of an hour, and from that to twenty minutes, being the time given for a 10 × 8 picture — we are only surprised that the artists were able to get anything at all. The length of time quoted may surprise some; but when it is recollected that the roof is 150 feet over the sitter's head, and that it is glazed with that peculiar green tinted glass which in the process of time is changed into all manner of colours, then the surprise ceases.

The size of the pictures taken is 18 × 10. By arrangement with the company, the price of each picture to the members of the late orchestra is 5s.; to the general public 7s. 6d. We need hardly add they are published by the artists, Messrs. Negretti and Zambra, of Hatton Garden, and of the Crystal Palace.

INSTANTANEOUS PHOTOGRAPHY.

(From Our Reporter.)

Mr. Skaife delivered a morning lecture in Mr. Hogarth's Picture Gallery, in the Haymarket, to a highly select audience, on Wednesday, the 8th ultimo, which afforded instruction, not only to the photographer, but also to the naturalist, the physician, the soldier, the sailor, the traveller, and the theologian.

The photographer was shown that the mechanical action of light on a photograph was identical with the harder effect produced upon a field of snow by trampling upon it. The physician was put on the track of internal disease by the breathing upon a film of collodion. The theologian was awakened by a startling heliographic revelation, and then the lecturer introduced to the meteorologist a new atmospheric phenomenon, discovered in the spray from the paddle-wheel of a Woolwich steamer, a small photograph of which, enclosed between two concave glasses, was handed round for the inspection of the *savants*, whilst the little instrument, called a *pistol camera*, with which the curious photograph was taken, was duly explained. And after touching upon the causes that led to photography on concave glasses, and the reason of their final abandonment, Mr. Skaife called the attention of his auditory to two enlarged views of the nomination of candidates, taken by his pupil with the pistol camera from on horseback. In order to convey an idea to the audience how this was done, the pupil was directed to snap his camera at the skylight where the figure of a man was perceived standing on the roof, which he did, and in less than one minute afterwards the resulting picture of the window with the man behind it was handed round to the astonished audience. At the conclusion of the lecture, the auditors eagerly availed themselves of the permission granted to examine the miniature apparatus that realised such extraordinary results, which, exclusive of the camera, consisted of a pneumatic Mackintosh developing box, so arranged that a rapid succession of instantaneous little photographs could be taken without the fingers of the photographer ever coming in contact with the chemicals. Lastly, it was demonstrated that one hundred of these little negatives could be taken at a cost for chemicals not exceeding one shilling.

Meetings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

This Society held its second meeting, on the 9th ultimo, in the large room adjoining the Walworth Lecture Hall, Mr. A. H. Wall in the chair.

Previous to commencing the evening's business the Chairman observed, that as that business was the important one of confirming rules and electing officers, and as doubtless many other gentlemen would join the meeting in the course of the next half hour, whose presence upon this occasion would be most desirable, he proposed the postponement of the more serious duties, and suggested that the gentlemen present should pass some little time in examining the objects of interest provided by the kindness of some of the members.

Some excellent stereographs, obtained by Fothergill's process and taken by Mr. F. Howard, were much admired for perfection of half tone, force of effect, and beauty of colour — one, a view of the Crystal Palace, gave some distant foliage with all the softness of aërial perspective, combined with wondrous perfection of detail. Some discussion arose respecting the most effective position for the horizontal line, both with reference to the picturesque and the stereoscopic results.

Mr. W. Ackland exhibited a new camera stand for landscape photography, very light, portable, and, when fixed, extremely firm. This gentleman also announced that he was upon the eve of an experiment of a singularly interesting description, of the success of which he had little or no doubt, and which he hoped to lay before the members on his return from the continent.

Mr. Leake put up, with extreme ease and speed, a portable tent of his own invention, which he described from personal experience as standing well against wind, and thoroughly answering the purposes of out-door photography, stating that during the last year he took at least one hundred 12 × 10 views in one similarly constructed. This tent consisted, first of a shallow box or tray, about thirty inches in length, eighteen in width, and two in depth, made of half-inch pine deal, strengthened by wooden blocks at the angles, and forming the table or bottom of the tent; secured to this was a gutta percha tray with a pipe attached, which, by acting as a sink, keeps the bottom of the tent always dry and clean. The lid of this tray formed the top of the tent. Round the inside of the bottom and outside edge of the top was secured the lining, forming three sides of the tent, and consisting of two thicknesses of black and one of yellow calico; sufficient light being admitted to work by, through the yellow, by a small square aperture in the black calico; light iron rods, about two feet five inches in length, supported the top when the tent was erected, and shut into the case when it was packed. Over the opening in front was suspended by hooks a curtain of the same description as the lining, large enough to wrap round the operator and exclude the most inquisitive of solar "prys." A small plate-box was placed in the tray, and packed with the lining, curtain, and rods, in the case. This tent was fastened on an ordinary tripod stand by a screw through its bottom; but Mr. Leake informed us that he had a very light portable stand for the purpose, and that this, with the tent, weighed fourteen pounds; that it could be made, with a fair margin of profit, for about a guinea, and carried very conveniently by the handle attached to its side. The tent exhibited was for pictures 12 × 10, but a smaller one was made for stereoscopic pictures.

No discussion ensued, inasmuch as the Chairman called attention to the business more particularly claiming attention.

The Chairman read the minutes of the previous meeting, and called attention to the steps which he, with the other members of the provisional committee, had taken for the formation of this Society. A set of rules being read ,were, with some few alterations, adopted. The meeting then proceeded to elect its officers for the present year, as follows: — *President*, the Rev. F. F. Statham; *Vice-President*, Mr. W. Ackland; *Treasurer*, Mr. F. Howard; *Honorary Secretary*, Mr. A. H. Wall; and the following gentlemen to form a Committee, viz. — Messrs. Cotton, Hannaford, Leake, Sen., Clarke, and Leake, Jun.

The Secretary then proceeded to receive the names of members, and announced that the number already given promised very favourably for the Society's future well-being.

As nothing formal characterised these proceedings (and business proceeded none the less smoothly for the same), a cordial warmth seemed to unite all present in a glow of social fellowship, which it is hoped may always exist to accelerate the progress of this infant society.

Exhibition.

THE EXHIBITION OF THE FRENCH PHOTOGRAPHIC SOCIETY.

(Continued from page 153.)

The first name on the catalogue is that of "The Sculptor Adam-Salomon," as he ostentatiously inscribes himself, and which, with his cognomen, admirably bespeaks the man. He exposes forty-two portraits, which are hung in the first court to the left on entering. Of M. Adam we were told to expect wonderful things; and it would have been better to have let imagination had her course, for the reality is disappointing. When I have said the poses are original I have said all I can in his favour; and yet, if I had a dear friend from whom I was parting, and wished to have a "striking likeness" of him, it is not to M. Adam I should take him. A sculptor having a hero, a great poet, or philosopher to immortalise, is expected to spiritualise — to idealise — his subject, because his work is to be handed down for public observation in after ages; but your friend is not to be put into a pose which is unnatural to him, and represents him as he is not. Here we have a repetition of little tables, columns, curtains, cords, tassels, and vases, pervading more or less all the frames — a style of portrait quite exploded in London. Generally the accessories and dress are the most studied and sharp in focus, while the human face divine is much out of focus, hazy, indistinct, too black on one side and too white on the other. Generally the portraits have a very dark appearance from improper development, though thickly varnished and much relieved by the broad gold frames. They appear to have been taken with four-inch lenses, and are mounted in cushioned shaped passe-partouts, of white cardboard. Perhaps No. 8 may be reckoned the best as to natural pose, light, sharpness, and development, though the hands are large and huge enough to be those of a "navvy."

Comte Aguado comes next on the catalogue. His specimens were at length found in the third court to the right, after we had had a trot all round the exhibition to discover them, thanks to the

bad arrangement of catalogue and numbering. He is a rich amateur, and has a good staff of assistants, and exhibits proofs printed from negatives on waxed-paper and wet collodion, which represent charming studies of trees effectively rendered. One of the most excellent stereographs I ever saw may be noticed; it shows a small rustic four-wheeled carriage, drawn by an ass along a road in the grounds of a chateau, and a white dog sitting on his hind legs holding the reins in his mouth, a groom walking at the opposite side of the spectator, who is pleased by the unstudied arrangement of the group, the marvellous sharpness of the whole, the equal illumination, the clearness of the proof and the depth of shades, so full of detail. It puts completely in the background the instantaneous views of Caldesi and Montecchi. Another feature to be chronicled is that this print is about double the size of the ordinary slide, and is viewed in a stereoscope of corresponding dimensions, which Monsieur Le Comte also contributes.

Viscomte Aguado displays also some of the novelties of the season. His views, taken at Montfermeil by the wet collodion and the Taupenot processes, have many inferiors. His series of *épreuves stéréoscopiques* are very amusing. There are views taken with the camera at a considerable altitude, and turned downwards nearly perpendicularly towards the ground, showing the human figure in various attitudes as seen directly under the eye, and producing new effects of "fore-shortening" or *raccourcissement*. I cannot speak so well of the reproduction of a lithograph after the famous picture by Winterhalter, of Her Majesty the Empress in the midst of her Ladies of Honour. The lithograph, when photographed, was probably badly lighted, and has a dullheavy aspect as if over exposed; nor is it very well printed, there is a white spot in the midst of it, no doubt occasioned by a bubble of air in the sensitising bath. The beautiful gold frame, *à chevalet*, surmounted by the imperial crown, is in good taste.

How is it Alinari Frères have not sent more than nine reproductions of designs by Raphael, from the galleries of Florence, Venice, and Vienna? What we do see whets the appetite for the remainder of their collection of this grand master, connoisseurs of whom, and whose names are legion, owe so much to photography for the faithful *fac-similes* it renders of breadth, shade, power, and the delicate and marvellous touch of his pencil. Of what incalculable value to the artist are these copies of the master's studies for his great pictures!

M. Asser, of Amsterdam, exhibits several proofs closely approaching the excellency of silver prints. They are by a new process, which he calls lithophotography. The stones from which the proofs are printed are placed side by side with them. The edges of the film which carries the subject has in some places left the stone, but on the whole there is much promise in his essays.

Baldus exhibits only one example of his skill, namely, the doorway of the library of the old Louvre. This is by no means one of his best, and shows unmistakably signs of photography under difficulties, although attempts have been made to touch out the thousand and one spots produced by dust, &c., in course of manipulation of the wet process. Why has he not exposed for the gratification of his admirers some of his effective views by his paper negatives?

Some of the views by Bernier, of Brest, are very meritorious. In two of them are the *forçats* at their work; their countenances are clearly defined, and show how man can be degraded by passion, depravity, and sin. These views must have been taken with very quick working lenses, for the attitudes of the groups of galley slaves are unstudied and of the moment. Thanks to the wet collodion, the pictures are clean, of good size, and are sharp to the edges.

Besson, a sharp tradesman, is not to be baffled out of his advertisement by the determination of the Society not to exhibit photographic apparatus, lenses, &c., which is highly to be regretted on behalf of amateurs as well as professional men, who are thus prevented from viewing, side by side, the improvements which are constantly being made by the various manufacturers, and thus giving facilities for the easy selection of the best. He forwards two views, which he entitles *Divers appareis de photographie d'apres nature*, representing a large camera for reproductions, a smaller camera for taking several views or portraits at one exposure, both from the designs of M. Bingham, and an assortment of rests, stands, pedestals, cleaning apparatus, and all the multitudinous appurtenances of photography.

Bilordeaux, who is perhaps the greatest manufacturer of photographic prints, exhibits some of his best efforts, though these are far from being up to the mark. Is not the production in great masses, the sending out into the market at a low price copies of engravings, &c., which, lacking proper material and care, will last but a very short time, a great evil? The duped purchaser, savage at his loss, throws the blame upon the body of photographers in general!

Bingham certainly ranks first in this exhibition in his particular branch—reproduction—for the excellency of his proofs, whether it be for their equal illumination, sharpness of definition, beauty of tone, or faithful rendering of the artists he represents. His contributions consist of forty-two subjects, after the modern pictures by Meissonier, Yvon, Paul Delaroche, Cabanel, Piloty, Alfred de Dreux, Horace Vernet, Wappers, Bellangé, Jalabert, and designs by Chéflart. La Rixe, the most beautiful of Meissonier's pictures, is reproduced the most perfectly of any painting I have ever seen. The print is a curiosity in more respects than one. It is the same size as the original picture; nevertheless, it equals it in delicacy, in power, and in gradation of colour, and is undoubtedly the best effort that photography has yet given in yielding us the value of tone and colour. It is alike an honour to the artist and the photographer. The printing is exceedingly good, of a rich violet; the mounting is upon India paper, and lettered with the title of the picture, and as being the property of the Queen of England. A copy of the same painting was exhibited at Kensington last year, but was only about one quarter the size of the present reproduction. One's attention is also arrested by No. 145, which represents the famous hemicycle of the theatre in the Palace of the Beaux-Arts at Paris, and painted by Paul Delaroche. This proof is about two feet long, and evidently required great skill in the photographer, owing to the extreme length of the picture in relation to its comparative lowness in height, and was so difficult a subject to render that one of the principal Paris photographers, after several months' efforts, had to relinquish it, when recourse was had to M. Bingham, whose success is therefore more creditable. The subject is so well known that it is unnecessary to say more than that it was entirely the work of Delaroche himself, untouched by any of his pupils. In the photograph we find fully defined the countenances of all the great artists of the past ages. It forms one of the series in the *Galerie Photographique*, published by Goupil & Co., which, from its choice character, has already an European reputation. Proofs are very tastefully mounted by this firm. The admirer of old paintings will be much pleased with the copy of Apollo and Marsyas, by Raphael, the lights, shadows, and definition being as good as if the reproduction were from a crayon drawing, and not from a picture renowned for its colour, drawing and tone, though browned with age and varnishes. A copy of this proof was exhibited at the last exhibition in London. The *Athenæum*, in its review at the time, asked, why was the photographer's name concealed? I could answer this question at length, but will content myself by saying, simply to hide the name of the successful operator, Monsieur Bingham, to whom the owner of the picture came over from England.

The copy of the painting by Alfred de Dreux, of the Emperor Napoleon III., is the best and most characteristic representation of His Majesty that has yet been published. He is seated on his favourite charger at a review, while the army defiles before him.

Bisson Frères are noted for their excellent reproductions of engravings, which have a sharpness and beauty of tone not surpassed in this exposition; they have also a reputation for their views of the monuments of France, &c., but of which they must take more care. No. 170, inscribed in the catalogue as central doorway of the Cathedral of Reims, is in reality a view of the lower part of the façade of Notre Dame, at Paris, but it is quite a caricature of the front of this church—the lines of the architecture, which should be perpendicular, rapidly converge from the ground line towards a common centre in the upper part of the picture, which defect quite destroys the effect of the design and proportions. Such deviations in a severe architectural view cannot be allowed to pass uncondemned. No. 171—view of the Hotel de Ville, Paris—is not equal to the view published by Baldus, which, strange to say, he does not exhibit. Nos. 172 and 173 are, perhaps, the finest proofs Bissons expose, and for the details of the sculpture, the lights and shadows, the very veins of the stone-work are not to be excelled; the perpendical lines and perspective of the architecture are faithfully represented. These two views are admirably printed from the negatives of M. Godet, to whom much credit for the excellency of his manipulations and judgment is due.

Disderi & Co. exhibit the best portrait in the gallery; it is one of very large size, taken by a lens made by Hermagis, sixteen centimetres in diameter, and is wonderful for its definition, modelling, and illumination. The mounting does credit to Disderi's taste, the *biseau* being of a pleasing shade of drab which, with lines of tooling and gold, relieves and adds value to the colour of the proof, which is well printed. There is a frame enclosing portraits, for

visiting cards, of members of the imperial family, which are as inferior as the abovenamed portrait is good. Prince Napoleon is represented like a Daniel Lambert; the faces are badly lighted and dark, as if under-developed. Disderi had lately the honour of receiving the Emperor, Empress, and the young Prince Imperial, at his *atelier*, on the Boulevards, the first photographer who has been so honoured. Messrs. Mayer and Peirson, to whom the imperial party had already sat, had the great disadvantage of having to operate at the palace, with such indifferent light as came from a window, and the inconveniences attending a temporary service: this was pointed out to their majesties, but they were unwilling, at that time, to visit any *atelier*. Mayer and Peirson were consequently unable to publish such excellent works as they are justly renowned for producing at their gallery, and it is to their greater credit that the stereoscopic portrait of the Emperor yet remains one of the best, if not the best portrait yet before the public. Let us wait to see what Disderi, who has profited by the objections of Mayer and Peirson, will do, for he is commissioned to print 20,000 proofs from the negatives he has taken. We are told that the little prince is headstrong and self-willed; and though Disderi says he succeeded well so long as he had the prince to himself, yet, when the Emperor and Empress arrived, and Disderi prepared for a group of three, his highness spoiled nearly every picture by moving during the exposure of the plates. The mode of operation, it is said, was thus arranged to save time and proceed with despatch: the glasses being all cleaned, one operator collodionised and sensitised them; Disderi posed, while a second operator focussed, and a third developed. Disderi's mode of operation was to count one to seven, while the plate was exposed, begging his august patrons to remain still until he pronounced the final seven! During one pose Disderi, chronometer in hand, commenced one! two! three! when the young heir to his father's greatness changing his posture to that of Achilles, in Hyde Park, shouted SEVEN! to the uncontainable but uncourtly laughter and amusement of the Emperor and Empress. But oh! ye photographers, what would you say of the perseverance of your great Parisian brothers, who previously having procured a model, and arranged him differently thirty or forty times, so as to secure an unimpeachable pose, the position of the hands, feet, and head, being all carefully marked for after use? judge then of and pity the chagrin of the unhappy Disderi at this *contretemps*.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER III. *(Continued.)*

ON COLOURS AS PIGMENTS.

Paints or pigments have properties apart from such as they possess merely as colours, viz.—purity of colour, transparency, quality of working, and of drying, body permanency, &c. — some knowledge of which is of evident importance to the embryo colourist.

As these instructions will combine colouring in oil, water, and powder, or dry colours, I shall now consider the various paints with regard to the requirements of these several processes.

The properties of pigments vary with the vehicles in which they are used, the grounds on which they are laid, &c.; and these properties are also modified through combination with other paints. Their colours are sometimes injured by light, or the absence of light, by pure or impure air, by damp, by oxygen, sulphureted hydrogen, &c. — some by one cause, some another, some more, some less. Many pigments must be altogether rejected by the conscientious artist, but we have plenty which are good, although some of these require the exercise of judicious care. I will now give a list of the principal pigments in use, pointing out the peculiar defects and advantages of each one.

WHITE,

The complementary of black, gives depth to, and harmonises with, all other colours. By mixture, it forms those tints of colour, which being nearly allied to light, at once catch the eye, by apparently advancing before the colours and shades about them; it should be pure and permanent.

In oil painting, an English white lead, called *flake white*, is most used. Too much oil should be avoided in its preparation and application, as it will otherwise become discoloured: a little black should be employed with it, to counteract its tendency to turn yellow. This pigment should not be used in water-colour painting, as, when unprotected by some "vehicle," it rapidly blackens.

In water colours the best whites are the "Constant" and "Chinese." *Constant white* is sulphate of baryta — *Chinese white* is a preparation of oxide of zinc: each of these possesses great advantages. White is seldom used in tinting with dry colours.

OF YELLOW PIGMENTS.

Yellow being closely related by its luminous character to white light, is always very prominent and attractive in a picture. Being a very delicate colour, its brilliancy is too easily lowered, and its primary beauty destroyed by mixture with other pigments; great care should therefore be directed to the preservation of its purity. Yellow pigments are very numerous; some are beautifully transparent, others opaque. I shall only name such as are more generally used. *Perfectly pure yellows* are very rare.

Gamboge — A most useful colour, both in oil and water — very bright and transparent: being a gum-resin, it serves a similar purpose to that of varnish in the preservation of other colours, more particularly when water is the medium. Although it is not quite permanent, it could with difficulty be dispensed with, especially by photographic colourists.

Indian yellow — A very rich full yellow (more useful in water than oil painting, being in the latter case very fugitive, but in the former tolerably permanent), is an urio-phosphate of lime; is not injured by foul air, and is sometimes (I think erroneously) called permanent.

Gall Stone — A very powerful golden colour, more eligible for water than oil medium, although not permanent in either; an animal secretion, chiefly in use among flower painters. It must be used with extreme care, and well shielded from chemical action.

Cadmium yellow — A very brilliant metallic production, permanent both in oil and water;* of tolerable power, and much used in draperies.

Naples yellow should not be applied in water, although such colourists as use body colour for painting flesh tints compound most of them with this dangerous pigment; protected in oil by varnish, it is however safe and very useful, working well, drying quickly, by becoming hard, and is almost indispensable in mixing flesh tints. It must not be brought into contact with iron; a pallet-knife of ivory should therefore be used, and such colours as contain iron avoided in its application to compounded hues; it is obtained from zinc and antimony.

Yellow ochres are not powerful or brilliant, but are the most ancient and honest of pigments, pleasing in hue, permanent, and working well in oil and water: they vary in colour from a rich broken yellow to a warm brown, are semi-opaque, and are always useful both in themselves and for compounding. They are earths.

Raw Sienna — An ochre; is permanent, and of good power; has more body than the ochres, and is more transparent; a very good and useful pigment both for water and oil.

Chrome yellows are very pure, bright, and of good body, useful in oil and water: their permanency is a disputed point, but few painters reject them. In mixtures they must be used with extreme care (Prussian blue is entirely destroyed by them). They are chromates of lead.

Lemon yellow — A delicate, permanent preparation from platina I use this instead of Naples yellow *in water:* it is somewhat opaque but works well either in touches or washes.

(To be continued.)

Errata.—In the last portion of this article two or three typographical errors escaped correction; they were, however, of but little importance to the sense, save the two following, viz.—in page 154, first column, for "the red *is* green," read "the red *its* green; for "art *interest*" read "art *student*."

Photography Applied to Musketry.—A series of interesting and valuable experiments have been made during the last few days, by Lieutenant Walker, 79th Highlanders, of the School of Musketry Staff, Hythe, in the application of the photographic art to the science—for such it has become—of musketry, with a view of obtaining, by means of the former, a true and exact copy of the target practice of a section, or any other number of men at one or more targets. We are glad to learn that these experiments have been attended with a most satisfactory result, Lieutenant Walker having established by them the important fact that, by means of the chemical influences of light, every "hit" or impingement of a bullet, however slight, can be transferred from the target to paper with an infallible accuracy, and a celerity which at once renders obsolete the former tedious and, oftentimes, inaccurate method of copying by the hand the impression made by each shot on the target's surface into a diagram, which had previously to be prepared for the purpose. This novel adaptation of photography will be found peculiarly useful in testing the comparative merits of different

* I have heard of no instance to the contrary, but it is a recent introduction.

firearms; and in these days of volunteer rifle corps it would prove highly useful and interesting if each company had a photograph taken of its target practice; and, as any falsification of returns would by this plan be rendered impossible, on a great comparison being made of them throughout the country, it would at once be seen to which corps belonged the palm for the best shooting.—*Hythe Gazette.*

Letters to a Young Photographer.

No. XIII.

My Dear Eusebius,

I had not the remotest intention of wounding your feelings in my last epistle. You crowed so loudly over your first chicken, that I thought it would do you no harm to set you down a peg, and take some of your conceit out of you. Had I not done so, you would doubtless have put an end to this correspondence, by turning round and commencing to teach me. I scorn to flatter, but am not tardy in rendering justice where it is due. I should have been but a blind teacher, and you the dullest of pupils, if by this time you had not arrived at some fair degree of proficiency; but to allow you to suppose you had reached the goal, would have been to stultify you for ever. It is just twenty years ago since I made my first photographic experiment, and although I feel as capable of obtaining a good picture as any of our craft, I am no more certain of a good result beforehand, nor of the power to command success, than I was at the commencement. You may consider this a very humiliating confession, but the fact is due to the delicate and subtle nature of the art. You may take pictures every day for a month with scarcely a single failure, when suddenly a flaw appears, which it takes a week or more to set right.

I have heard of photographers who were born such. They came forth, like Minerva from the head of Jove, full grown and full blown, but I avow I never saw one. Once upon a time I looked into the operating room of one of these conjurers, and saw a woeful waste of nitrate of silver, and a perfect chaos of bottles, dishes, baths, pewter pots, and tobacco pipes, but I saw few good pictures. I was forced to the conclusion that the professor bought his triumphs ready made. But cheer up, my dear Eusebius. You are as far advanced in our art in the short space of six months as I could have been in twelve years, because I had to await its growth and development. Your name is wafted from Indus to the pole. The printing-presses of America, India, and Australia, spread the name of Eusebius far and wide over the ever-extending map of the civilised world; and should you ever make a visit to New York or Philadelphia, you will be fêted in such a style as will make Dickens and Thackeray envious. Your productions will be sought for with avidity by the connoisseur collectors who love to enrich their portfolios with the treasures of our art. Eusebius, you are born to greatness—I will not thrust it upon you. But, *credat Judæus!* there are heretics who would deny your existence—who would persuade their dark little world that you are only a myth! Send the certificate of your baptismal register to our publisher, and he will publish it in his next number, and so prove to the world that Eusebius, the son of Theophilus, is of good descent, and can flout at the witlings of Tooley Street.

But truce to this digression—let us resume business. Your last pictures, which the carrier has just brought me, arrived in good condition, and I can honestly pronounce them better even than your first picture, which, seriously speaking, was very good. Do abate one jot of care and skill in your manipulations: success is not apt to make us careless, and you may soon find yourself floundering in a slough of despond, amid fog, spots, streaks, stains, and all the other mosquitoes of the operating room.

But "summer is a-coming in," as the poet sings, and you will be longing to start on a campaign, to try your prowess in the tented field. You will want the best "preservative" process, or the most perfect "dry" process. You will be debating the merits of Taupenot, Fothergill, and Despratz, and decide upon employing turpentine-waxed-paper, because it is the least cumbersome, and will enable you to dispense with a "navvy" to carry your knapsack. I shall, therefore, devote the remaining space of this letter to the details of that process, because it is one that has many recommendations to the neophyte, who is very apt to be discouraged by difficulties. I have pictures taken by the turpentine-waxed-paper process, which few would believe but that they were printed from collodion negatives.

Turpentine, it must be confessed, is not so savoury as raspberry syrup, still it is not to be despised. I could save myself a great deal of trouble if, instead of describing the *modus operandi* of this section of photography, I were to tell you to buy a shilling pamphlet upon it. But that would be ungenerous and unkind. I know to my cost how little can be got from books by those who are ignorant and seeking information. Few who write on these matters possess the art of communicating their instructions in a clear, concise, and methodical manner, or of arranging their ideas in the proper order of succession. Mounting on stilts, they can rarely descend to the level of the understandings of the uninitiated. In fact it is no easy matter to address intelligibly those who know nothing of the subject under consideration. It is absolutely necessary to presuppose a certain amount of knowledge in the learner, which becomes a stumbling block to his understanding. After this admission, it may seem something like arrogance in me to proceed, but I do so at all risks.

It is of primary importance to obtain paper of the best quality for this process. You can buy Marion's paper ready prepared, but you can prepare it yourself in the following manner:—Dissolve in one pint of camphine one ounce of pure white wax, and add to the solution two drachms of pure iodine. The mixture becomes violently agitated, and of a deep red colour, which afterwards changes to a golden yellow. Then add to it two ounces by weight of castor oil. Immerse the paper in this compound for three or four minutes; it becomes transparent and like parchment in texture. Hang it up to drain and dry, and then keep it between the leaves of a blotting book until required for sensitising. It will keep in good condition for some time.

This paper, when sensitised upon a nitrate of silver bath, yields very good negatives; but the paper not being very sensitive, it requires a long exposure in the camera. By employing a second process the exposure may be materially shortened, in fact the paper may be rendered as sensitive as collodion.

A sheet of the waxed iodised paper is floated for about fifteen minutes on the following solution:—

Water	20 ounces.
Sugar of milk	1 ounce.
Iodide of potassium.	3 drachms.
Bromide of potassium	40 grains.

The sensitising bath is composed as follows:—

Distilled water	8 ounces.
Nitrate of silver	4 drachms.
Iodide of potassium	4 grains.
Acetic acid	4 drachms.
Citric acid	4 grains.

When sensitising the paper you will require three dishes—one to contain the filtered nitrate solution, the others to contain distilled water. The paper is to be floated on the solution until it loses its red hue, which will be in two or three minutes, then removed to the first dish of water, and freely moved about in it, and next transferred to the other dish, and when well washed hung up to drain and dry, first removing the excess of moisture by placing the sheets between folds of blotting paper. This operation must be carried on in a darkened room.

The time of exposure in the camera will of course depend upon the intensity of the light; it will vary from half a minute to two or three minutes: be careful to avoid over-exposure. Development should be effected on the same day as the exposure if possible: sometimes the paper will keep in good condition longer, if placed in an air-tight box, but it cannot be implicitly depended upon. The developing solution is made by adding four ounces of a saturated solution of gallic acid to four ounces of water and eight minims of the sensitising solution. Float the paper, exposed side downwards, for a few minutes upon this bath, until the paper becomes flat and the image has begun to appear, then with a glass triangle push it into the solution, and keep it beneath the surface—a task of some difficulty, as the paper, being saturated with wax, will not easily become wetted, and rises to the surface. The development must be prolonged until the sky appears intensely black, as the intensity becomes much reduced in the subsequent fixing solution. If the proofs acquire a dirty yellow colour in the developing bath, it is no prejudice to them, they will still yield good positives. When the proof is thoroughly developed, wash it in two changes of water, and then fix it in a solution of hyposulphite of soda, of the strength of two and a half ounces to the pint of water. When the yellow iodide is all dissolved out, wash the proof for three or four hours in several changes of water, then remove the moisture by placing them between folds of blotting paper, and suspend them in the air to dry.

If the proofs present a mottled appearance, hold them before a clear fire; they may possibly require a second waxing, which is performed in the usual manner.

J. P.

Photographic Glossary.

Nitrites — Salts formed by the combination of nitrous acid with the bases. The only one of interest in photography is the nitrite of silver.

Nitrite of Silver — A compound of nitrous acid and oxide of silver, containing one atom less of oxygen than the nitrate. It crystallises in long slender needles, soluble in one hundred and twenty parts of water at 60°. Fused nitrate of silver is apt to contain nitrite, which, when present in a nitrate bath, is liable to produce fogging.

Nitro-Muriatic Acid: Nitro-Hydrochloric Acid — A mixture of hydrochloric and nitric acids, called also *aqua regia*, as it enjoys the property of dissolving gold, the king of metals. If a metal is immersed in this compound it dissolves rapidly in the state of chloride. The metal encounters chlorine in the nascent state under circumstances in which the combination takes place most easily. *Aqua regia* acts as a very energetic oxidiser.

Nitrous Acid—An acid which contains two atoms less of oxygen then nitric acid. When dry binoxide of nitrogen and oxygen gases are mixed in proper proportions and exposed to the temperature of zero, they condense into a limped blue liquid, which is nitrous acid. It is decomposed by water, therefore cannot be made to unite directly with the metallic oxides; but a well defined series of nitrites may be formed by indirect means.

Nordhausen Sulphuric Acid — Fuming sulphuric acid. It is a combination of two equivalents of sulphuric acid and one equivalent of water; its density is 1·90. It is distinguished from ordinary sulphuric acid in containing less water.

Nitrogen — A colourless, inodorous gas, unsuited to respiration or combustion. It forms, however, nearly eight-tenths of the atmospheric air. Its combinations with oxygen are very important in chemistry and the arts, especially nitric acid.

Objective — The name given to the various combinations of lenses employed in photography. It is a useful word, as it expresses the series of lenses which combine to form a compound, which is commonly but erroneously termed the lens. The origin of the word objective is in consequence of the compound in the telescope and microscope being towards the object.

Oxalates — Combinations of oxalic acid with the bases. Those of most interest to the photographer are the oxalates of iron, silver, and soda.

Oxalic Acid — This acid is found in very considerable quantities in various vegetables, combined with potash or lime, and it may be prepared artificially by the action of nitric acid upon sugar, starch, cellulose, &c. It is white, solid, of a sharp sour taste, soluble in water and in alcohol. It is a very active reducing agent, and is capable of playing an important part in photography. Its solution reduces the salts of gold with facility.

Oxides — Compounds formed by the direct union of oxygen with other bodies, bear the general name of *oxides*, which are, for convenience, divided into three principal groups or classes. The first division contains all those oxides which resemble, in their chemical relations, potassa, soda, or the oxides of silver or of lead: these are termed *alkaline*, or *basic* oxides, or *salifiable bases*. The oxides of the second division have properties exactly opposed to those of the bodies mentioned: oil of vitrol and phosphoric acid may be taken as the typical representatives of this class; they are called *acids*, and they tend strongly to unite with the basic oxides. When this happens what is called a *salt* is generated, as sulphate of potassa or phosphate of silver, each of these substances being compounded of a pair of oxides, one of which is highly basic and the other highly acid. The third group, from their slight disposition to enter into combination, are *neutral* oxides, of which the black oxide of manganese is a good example. It very frequently happens that a body is capable of uniting with oxygen in several proportions, forming a series of oxides to which it is necessary to give distinguishing names, such as the protoxide, binoxide or deutoxide, teroxide or tritoxide, sesquioxide, peroxide.

Foreign Correspondence.

Paris, June 25, 1859.

When we consider how wide is the domain, and how extensive the applications, of photography, we cannot but be surprised to see how slowly they are recognised, and how little apt we are to avail ourselves, not only of the unique facilities afforded by photography, but of many other discoveries of modern science. There is a morbid eagerness for the *new*, but a singular apathy in adopting it when found. Discoveries of the utmost importance are repudiated simply because they disturb our habitual notions, and involve the necessity, in accepting them, of a change in habits. I do not know of a sadder or more humiliating task than that of looking over the annals of discovery and invention. Things, which if adopted by society, would affect great improvement in its social condition and welfare, lie dormant and unproductive for no other apparent reason than because they were not familiar to the past generation. Many of them are rediscovered, and bring loss and disappointment upon the discoverers. A list of the discoveries and inventions of the present century, for instance, having for their object the improved ventilation and heating of our dwellings, with other items of domestic comforts, would fill a volume. Yet not in one house in a hundred will you find them introduced. And so it is with many other things. The world appears to prefer its old ways, with all their inconveniences, to the adoption of new ones; just as the individual prefers his old shoes and coat to the new, simply because they fit easy.

Photography has not fulfilled a tithe of the indications it promised. It is too much limited to mere pictorial representation. Its value as a most accurate delineator is generally admitted, but very seldom acted upon in the majority of instances where its aid would prove of the utmost importance. The artist accepts its aid with a certain air of condescension; acknowledging its value but neglecting its assistance, he acts as if he were jealous of it. The architect but rarely invokes its aid, nor does the engineer or surveyor. The microscopist and the astronomer make a show occasionally of applying it to their respective pursuits, and now and then the surgeon employs its aid in delineating bases of extraordinary deformity, or of uncommon interest. But it is to pathological science that the peculiar resources of photography promise the most important results. I have seen at Clamart some stereoscopic views of regional anatomy, with representations of the lymphatic vessels. Any one who has examined drawings of these objects will acknowledge how extremely difficult it must be for the hand of the artist to trace what his eye perceives. In fact it requires that the artist should be also an anatomist. A photographic artist is permanently attached to *La Clinique*, whose special office it is to obtain representations of cases both before and after operations, thus providing a record of each interesting case which will be useful hereafter, not only as a reference but as a means of instruction. I have lately examined with the deepest interest some exquisite photographic illustrations of comparative embryology, taken by an enthusiastic anatomical friend of mine, which when given to the world will excite, I am sure, the greatest interest and admiration. This series of human embryology is complete; he has obtained delineations of the fœtus, at every stage of growth, at intervals of fourteen days. He has also a series of the sheep, another of the dog. Another series represents every succeeding day's progress in the incubation of an egg. After viewing these representations, and comparing them with engraved plates of the highest class, I could but award the palm of superiority to the photographer, and I felt proud, too, that I was myself a humble follower of so valuable an art.

What artist has ever succeeded in depicting the diseases of the eye? But the photographer steps boldly forward, exclaiming, "That task is mine!" M. Cusco, an eminent surgeon has, as I lately intimated, obtained photographic images of abnormal conditions of the choroid, taken both from the living subject and the dead, which possess much interest and value to the ophthalmist. The anatomical changes of the deeper membranes of the eye can only seldom be verified by direct examination: their decomposition takes place very rapidly, consequently they are but little known. But ophthalmoscopic observations increase daily, demanding strict anatomical control, which alone can fix the opinions of pathologists as to the value of these operations. Nothing will better conduce to this end than photographic images of these occular lesions. The images exhibited by M. Cusco are (on a scale of 2½ diameters), *(a)* the papilla; *(b)* a large portion of the choroid, deficient both of pigment and vessels, and where the sclerosique is seen by transparency; *(c)* on the side opposite to

the papilla, a smaller spot of the same kind; *(d)* a wave of pigment circumscribing the papilla on its interior; *(e)* the circumferential portion of the choroid, in nearly its normal condition. Those who are acquainted with the difficulty of treating diseases of the eye will appreciate these photographs at their true value.

My esteemed and learned friend, Dr. Ducheune, lately showed to me his "physiognomical album," which is a new reading of Lavater. The album represents the muscles of the face excited by electricity. The subject operated upon was an old man, one side of whose face was paralysed. The results are very curious and instructive.

In the human face there are great lines which command the expression of the rest; the eyebrow is one of these, and the principal one: raised by means of a muscle which occupies the forehead, it expresses astonishment, surprise, or attention, On this account M. Ducheune calls the frontal *the muscle of surprise.* This action may be observed in the pit of a theatre at the moment of the rising of the curtain, when the eye opens widely to receive the impression which comes to it from without. The opposite action, the lowering of the eyebrow, is produced by the upper portion of a muscle which enters into the composition of the eyelids, and which is known under the name of the *orbicular.* Its contraction expresses reflection, and for this reason is called the *muscle of reflection.* A small muscle situated in the eyebrow, is called the *muscle of pain,* as it produces the expression of it when it is in action. Another muscle, the pyramidal, placed across the root of the nose, appears intended to express wickedness; its energetic contraction produces an indescribable expression of ferocity upon the physiognomy: it has received the name of the *muscle of wickedness.*

Two other muscles, situated on the cheek, near the cheekbone, are the large and the small zygomatic, they produce weeping and laughter. There are many other muscles whose functions of expression are exhibited in this album, but as they occupy a less important rank than those named I pass them by.

To appreciate the amount of influence exercised upon the expression by each of the muscles, the contraction of each was successively provoked at the moment when the physiognomy was motionless; and the experiments were rendered more complete by the subject, in whom all the passions were in their turn evoked, being an old man, whose face was paralysed on one side. The contractions effected were first simple and isolated, expressive or inexpressive; then, proceeding from the simple to the complex, the muscles were contracted two by two, three by three, and in this manner compound contractions were obtained, which are termed concordant when they express a single passion, and discordant when, on the contrary, they result in producing only grimaces. There are some muscles which enjoy the privilege of depicting by their individual action an expression which is peculiar to them — their simple contraction is then completely expressive. This effect was formerly attributed to simultaneous contraction of many muscles. The researches of Dr. Ducheune show that this apparent general contraction of the features of the face is only an illusion produced by the influence of the lines of the eyebrow and of the forehead upon the other features, without other action than that of a relation of proximity, such as may be observed in different colours placed side by side. In each study care was taken to excite only one side of the face at the commencement, leaving the other motionless; so that by covering them alternately, we may judge of the change effected in the picture submitted to observation. Here we have developed a sort of living anatomy, which ought to be useful to artists. The physiologist will be better able to appreciate the functions of every muscle. The photography of the passions is delineated! But I hear the loud booming of the cannon at the *Invalides* — another glorious victory, I suppose! — Adieu. J. P.

Correspondence.

LUNAR STEREOGRAPHS.

To the Editor.

Sir,—In the early part of 1853, I took several collodion positive pictures of the moon, with the assistance of Mr. Thornthwaite; and as favourable circumstances presented themselves, I continued to do so alone, *and I frequently placed two photographs, obtained at different epochs in the stereoscope,* and proved to myself that a stereoscopic effect was obtainable in a greater or less degree. At that time I invariably placed the pictures in such a position as they apparently occupy in the astronomical telescope; but having resumed my experiments in 1857, it occurred to me to avail myself of the moon's libration in latitude, and to fix the pictures in any position suitable for this object, however much they might require to be turned round from their apparent position in the telescope. The immediate result was that globe-like representation of the moon for which I had long sought; and having satisfied myself, I took an early opportunity of showing the result to my friends; but I do not think that I exhibited publicly my lunar stereographs *thus* obtained until October, 1857. — I am, yours, &c. WARREN DE LA RUE.

The Observatory, Cranford, Middlesex, W.

OXALIC ACID IN COLLODION.

To the Editor.

Sir,—In your remarks in the last number of The Photographic Journal upon what was stated by my friend, Mr. Williams, at the May meeting of the Photographic Society, you say, that "from the residues of twenty Winchester quarts of old collodion, no less than 1lb. 5ozs. of oxalate of lime were obtained.

As this was not the impression conveyed to my mind by what fell from Mr. Williams upon that occasion, I have drawn his attention to the matter, and have his authority to state (preparations for a journey to the continent preventing his communicating with you direct), that what he found was, not 1lb. 5ozs. of oxalate of lime, but enough *oxalic acid* to form, by precipitation with a lime salt, 1lb. 5ozs. of that substance. Since that time, on repeating his experiments upon other samples of collodion residues, iodised and uniodised, made with pure and methylated spirit, he has noticed the following curious fact, viz. — that old iodised collodion yields oxalic acid; while plain collodion residues, whether made with pure or methylated alcohol, or ether, are found free from it. At the present moment, it is of course impossible to indicate the source of this substance, or the combination in which it exists. But I am sure the matter cannot be in better hands, and that upon Mr. Williams's return to England he will continue his experiments with a view to the elucidation of it.

You will pardon my intruding so much on your time and space; but the question is one of very considerable importance, and I think your observations might have a tendency rather to divert the attention of those who have the opportunity of working upon the subject out of the right channel.—I am, yours, &c.

JOHN A. SPENCER.

7, Gold Hawk Terrace, Shepherd's Bush, W.
June 11, 1859.

[We are always obliged by the correction of any error into which we have inadvertently fallen. The subject is one of great importance; but, independently of that, we are always glad to hear from Mr. Spencer.—Ed.]

DIFFICULTIES WITH DRY PROCESSES.

To the Editor.

Sir,—The great readiness and kindness you show in endeavouring to extricate the readers of your Journal from their difficulties, induces me to trouble you with mine.

Wishing to master one of the dry processes for taking landscapes, I began with trying the preparation of small plates; in doing this, I have entirely failed. I have prepared plates with metagelatine and with albumen, by Fothergill's and Lloyd's modes, and also preceded them by coats of albumen and gelatine, as done by M'Nab and others, and always had pictures showing more or less by transmitted light as if the film had been full of blisters. At first I attributed this to imperfect cleaning, and tried all plans of cleaning that have been proposed, also baking after cleaning, but without success; new and recleaned glasses have given the same results. I then attributed the defect to the collodion, which was old and slow, and procured a supply of Keene's, but the pictures were still marked in the same way. Some, when fixed and washed, showed blisters, others only the marks of them by transmitted light. Nothing of the net-like appearance can be detected in the early stages of development; it is only when it is pretty far advanced it shows itself, and it is not fully seen till the plate is clean. Iron and pyro-developers both give the same appearance.

I am quite at a loss to imagine the cause. My nitrate bath was made chiefly new about six weeks ago, and has not been much used; it is neutral, and gives a good wet picture with Keene's collodion.

Last night I cleaned carefully three new small plates. No. 1, I coated with dilute albumen; dried thoroughly at the fire, collodionised, sensitised, dried the back of it, put it two or three minutes in a bath of albumen, diluted about thirty times with water, making the albumen flow back and forward over it, washed it with a good quantity of water flowed over it, and placed it on blotting paper to dry. No. 2, I treated in exactly the same way, omitting the first coating of albumen. This morning I took three views of the house opposite my window, Nos. 1 and 2, on the two prepared plates, and 3 on a wet collodion picture—the same collodion, bath, developer, and cyanide being used for all. No. 3 was exposed three seconds, and gave a good picture, free from defect in the film. Nos. 1 and 2 I send you, both showing the defect I complain of. The markings in different plates vary greatly in size, as you will see in the skies of two trial prints which are enclosed.

The two plates I send were both alike when first completed, but thinking to make them safer for carrying, I wetted them, and poured some very weak gum-arabic on, which has greatly changed the appearance of No. 1. This plate showed blisters when drying. The change on the film by the gum does not affect the reticulated appearance to be seen by transmitted light.

If you can help me by directing me into the path so many say they find easy and certain, I shall be exceedingly obliged to you.

I only want to get into the practice of some mode pretty certain in its results, to use as an amusement, and which I can leave off and resume as my other avocations allow me. Begging you will excuse the trouble I give you with this, I am, yours, &c. J. W. M.

[Your case is well stated, except that you have omitted the details of development. We replied to you shortly in our last, and now proceed to give more extended details of manipulation, which we have no doubt will answer your purpose perfectly.

The marks you allude to are due to the condition of the collodion before immersion in the sensitising bath, but even these would probably not have shown had your exposure in the camera been longer, say double the time you have previously given. In warm weather, the more quickly you get the whole plate covered with the collodion the better as a rule. If it will not flow readily, add a little chloroform, as directed in our last.

Proceed as follows:—With the same collodion you have been employing coat your plate (either previously albumenised or not), and when well set immerse in the nitrate of silver bath. When ready remove and drain well. Avoid touching it with the naked fingers, but use india rubber finger stalls kept solely for the purpose. Attach a pneumatic plate-holder to the back, and pour on *two drachms* of distilled water for a stereoscopic sized plate. It will probably not flow well, but keep it in motion (which with the plate-holder is readily done), and, if necessary, pour it on and off with the measure *until it does cover the whole plate without showing any streaks.* Pour off and again drain well. Take of dilute albumen (as under), one drachm, and still holding the plate by the pneumatic holder, pour it along one edge, and make it flow regularly across the plate by slightly inclining it, let the surplus drop off at the further corner (which it will do appearing milky), and when it ceases to drop, or nearly so, leave the plate in a horizontal position, by standing down the plate-holder for about a minute, while you prepare the next plate; then take it up and hold it under the tap, or with a spouted jug pour on it common filtered water very copiously, to wash away as much albumen as possible, pouring the stream on the centre of the plate, and allowing it to flow off from each edge in succession. Lastly, flush it with a small quantity of distilled water, just enough to cover it, and set it on end to drain and dry. When apparently dry, unless it be kept for several days before use, it will still want artificial heat; if so, place it for a few minutes upon a *hot brick.* It is more sensitive, and less liable to blister if perfectly dry.

After exposure, when you wish to develop, just wet the surface all over, under the tap or otherwise, and drain pretty closely; cover it with your developing solution, to which a few drops of solution of pure nitrate of silver have been just previously added. The developer may either be an iron one, or gallic or pyrogallic acid; the first restrained by the addition of citric or sulphuric acid—(formulæ given in recent numbers)—or the last by citric or acetic acids; gallic acid requires no restraining acid, but takes a longer time to do its work. In cold weather we prefer iron, in hot, pyrogallic and citric acids.

The albumen solution to be made as follows, viz.:—

White of egg	1 ounce.
Liq. ammoniæ	15 minims.
Chloride of ammonium	8 grains.
Water	7 ounces.

Mix, put into a large bottle, and shake well. Allow it to stand before using for twenty-four hours, and filter through sponge or cambric. It will keep good for a very long time.—Ed.]

PHOTOGRAPHIC DIFFICULTIES IN INDIA.

To the Editor.

Sir,—Encouraged by the prompt and obliging way in which you answer correspondents who consult you respecting their photographic difficulties, I take the liberty of asking you to be so good as to assist me in getting out of a mess which I have got into in practising, or rather attempting to practise, Long's calotype process, as described in pages 174 to 179 of the *Journal of the Photographic Society* of the 22nd December, 1856. The paper is headed "Modification of Paper Processes," by Mr. Charles A. Long. I am told that Mr. Long is a *first-rate* photographer. However that may be, I cannot manage his modified calotype process at all; and I am very desirous, therefore, of getting the opinion of so eminent a critic as yourself upon it. In case you cannot conveniently refer to that number of the London Journal, I quote Mr. Long's own words:—

"Take of gelatine half an ounce, and dissolve thoroughly in one quart of distilled water. When quite dissolved, add one and three-quarter ounces of iodide of cadmium. Stir the mixture, still warm, until the whole of the cadmium salt is dissolved; then throw it into a 'funnel' and filter," &c.

This is Mr. Long's cadmium iodising solution. But *I* cannot make it; for the instant I commence adding the cadmium, the whole coagulates into a mass of sticky gluten, adhering to every thing most unpleasantly. With a great deal of perseverance I could not bring it into solution. I have tried *repeatedly*, and met with the same disappointment; and yet Mr. Long speaks in the highest terms of this process. I am all the more anxious to succeed in making a good cadmium-iodised paper, because I have an idea that it would be just the thing for such a climate as this. I need scarcely say, then, I shall be very much obliged if you will kindly indicate the probable cause of my failure, or suggest a better way of making a good cadmium calotype paper for use with gelatine. I shall anxiously look for your reply in the June or July number of your Journal. A really good *paper* process is still a desideratum out here. The collodion process can only be worked out here, with any degree of certainty, during four months of the year. Do you think that the new alcoholic collodion (Mr. Elliot's?) would do very well out here during the *hot* weather? If you think you can recommend the trial of alcoholic collodion, you would, I am sure, confer a great boon on many photographers in India, by inserting in your Journal a good formula for making it, mentioning, especially, the specific gravity of the ether and the alcohol, and the description of gun-cotton best adapted.

I have one more favour to ask. Can you recommend Mr. ———'s new *Petzval* combination of *portrait* and *landscape* lenses, which he makes in this way:—

A, B, and C are used together for portraiture; but for landscapes the back lens and cell *C* are removed, A and B remaining in the same position as for portraits. The diaphragms go in at E.

If this principle is a really good one, I cannot understand why there should be so great a difference between Mr. ———'s and Mr. ———'s prices.

The last mail has brought out news of Mr. Sutton's new architectural lens—"Sutton's Triplet." Can you speak favourably of it? I want to order out a first-rate landscape lens, but I am at a loss which to get. I would prefer a *good* combination for *portraits* as well as landscapes.

Excuse my troubling you with such questions. We poor photographers out here have not half the advantages of people in England in regard to consulting such eminent authorities as yourself. Your Journal is very popular in Calcutta. I sincerely hope your letters to "Eusebius" will enter fully into the subject of lenses and cameras.

I nearly forgot to mention that the beautiful specimen of photolithography, published in your Journal of the 1st February last, has created a great sensation out here.—I am, yours, &c.

Calcutta, 8th April, 1859. PLASSEY.

[Salts of cadmium and some other metallic bases coagulate albumen, but we are not aware that they have the same effect upon gelatine. What kind of the latter did you employ? We think if you dissolve your iodide of cadmium in water before adding to *ordinary* gelatine solution, you will avoid the annoyance complained of.

Should we return to paper negatives at any time, we should be inclined to follow a suggestion thrown out some time ago by Mr. Mayall, and take albumenised paper as a foundation to work upon.

The ordinary albumenised paper prepared for positive printing might be floated upon the solution as given by Mr. Long, and after drying, sensitised on the aceto-nitrate bath in the ordinary way, and slightly washed before use in the camera.

By attaching a sheet of albumenised paper to a glass plate at its angles, it could be readily covered with iodised collodion; if then immediately detached and floated on the usual sensitising bath, and afterwards washed and dried, a sheet of sensitised collodionised paper would be the result; but from certain experiments we have made, we have reason to expect that the picture, after exposure, would be *on the albumen,* and would be capable of development with pyrogallic and citric acids.

We see no reason why, in India, plates prepared by Fothergill's process should not be admirably available. Collodion, with a large proportion of alcohol, we think, would be advisable in a hot climate; but we are not sufficiently acquainted with the actual working of what Mr. Sutton has called alcoholic collodion to be able to recommend it with any degree of confidence, though we think it very likely to be good. Mr. Sutton's published formula is as follows:—

Methylated ether, S.G.·725	2 fluid drachms.
Methylated alcohol, „·800	6 „ „
Pyroxyline	8 grains.
To 3 ozs. of the above add 1 oz. of alcohol, as before	9 parts.
Water	1 part.

In 1 oz. of the above dissolve 14 grains of iodide of potassium.

The iodiser introduced by Mr. Mayall, as given in a recent number of The Photographic Journal, would very probably be useful for your purpose.

As regards lenses, you must remember that some kinds of glass vary much in density, and consequent dispersive power. This variation requires more careful adjustment of the relative curves of the different surfaces to get the best effect than novices are aware of; and as it is easier to cultivate the *hand* than the *brain,* those who require the work of the brain must pay a price accordingly. This will account for a great difference in price demanded by two makers for what is *apparently* the same thing.

There is a mistake in your apprehension of the method of using the lens alluded to; the *three* combinations are not intended to act together, but the front and back alone for portraits, and front and middle only for landscapes.

We think you had much better not attempt to make the same lens do duty in two capacities, something must be sacrificed in quality to effect it. If you can afford it, you had better buy two separate articles. The lens you mention last is cumbersome, and only intended for one purpose. It is also very slow in action.—Ed.]

DEVELOPMENT AFTER FIXATION.

To the Editor.

Sir,—With reference to the various theories which I see given for the development of prints after being subjected to the action of a hypo solution, I would be much obliged if you or any one will inform me whether it has yet been ascertained, by *actual analysis*, that silver in any style is contained in the image left. Should it turn out that there is actually *no* silver left, the possibility of producing an image by after-application of silver along with gallic acid, would indicate that the phenomenon was owing either to some wave power "impenduelle" or other influence disengaged during actinisation, by the silver salts having been retained by the film; or else to the film having been thrown into some state of change analogous to eremacausis, rendering it a silver reducer.

I am, yours, &c. C. J. B.

CYANIDE OF POTASSIUM IN FOTHERGILL'S PROCESS.

To the Editor.

Sir,—You will much oblige by answering in your next number, if possible, the following queries:—

(1) Is the use of cyanide of potassium incompatible with that of *Keene's collodion?* I have scarcely patience for hyposulphite, but cyanide makes the film so tender, that it is next to impossible to keep it all on the glass during the last washing. Must I resign myself to the tender mercies of the slower salt, or is there any way of making my *fast* friend behave a little better?

(2) Does it hurt the nitrate bath to filter it rather frequently, say once a week? My photographic room has to answer for chemical laboratory, carpenter's shop, and sundry other uses, and it is not possible to keep all my solutions quite free from dust always; even if I keep them covered up dust will float in the atmosphere.—I am, yours, &c.

London, June 23, 1859. A. H. B.

[1. Not incompatible with Keene's collodion in particular; the chief objection to its use being, that in conjunction with albumen the *intensity* is so reduced that a redevelopment is frequently necessary. The tenderness of the film is possibly due to the removal of the albumen by the cyanide of potassium. We think you will really *save time* as well as get a better picture by employing hyposulphite of soda.

2. Not if you keep a funnel and filter paper exclusively for the purpose, using the *same* paper repeatedly.—Ed.]

FOTHERGILL'S PROCESS.

To the Editor.

Sir,—As you have published "I. H.'s" letters, so strongly condemning Fothergill's Process, will you kindly find room for a few words in favour of it, from one whose experience has been just the contrary of his. I have tried it under every disadvantage, viz.—an acid bath used for positive portraiture, old collodion, that from age was quite useless for any other purpose, and some albumen that was prepared for coating plates as directed by Mr. M'Nab, about two or three months old. With the first plate so prepared I got a negative of a building "that was badly lighted" in six minutes, a print from which I enclose, with Goddard's lens, 13 inch focus, ½ inch stop. I have also used the process with Lloyd's modification for printing transparencies, and my success has exceeded my most sanguine expectations. I do not think anything can be more certain or less troublesome. A few days since I received three prints from a gentleman in Ireland who has worked Fothergill's process. Two of the prints were by that process, and one by wet collodion. The two from the dry plates were far the best: they were equal in manipulation to any that I saw in the Crystal Palace at Sydenham, about six months since.

Now, respecting Keene's collodion, the following facts will go some way in proving its qualities. A gentleman here, a member of the Photographic Society, sent for some of Keene's collodion, and prepared twelve plates, six of them by Fothergill's process, and six with oxymel. I went with him on one excursion, and he exposed seven plates: five were really beautiful negatives, and the others were pretty good. One of the oxymel negatives proved to be, *in every respect*, equal to wet collodion. I have never before seen any dry process give such beautiful results as that of Fothergill's.

GLYCERINE *versus* SUGAR.

Messrs. Murray and Heath have offered to photographers a substitute for the very easy and certain process first published by me in this Journal, nearly twelve months ago, for "deferring the fixing of negatives." There may be *chemical reasons* for so doing, similar to the raspberry syrup instead of oxymel; but I know the glycerine will not answer so well, and advise photographers not to try it. The glycerine will fog the plate in a few hours, while by using the syrup plates will keep for a week, as I have proved by *actual experiment*. I, when in London last, about six months since, called upon Messrs. Murray and Heath, and suggested to some one there to use the syrup in a bath, instead of water; and also mentioned that the proportions were to be found in your Journal and in a contemporary publication.

You have kindly gievn me the credit of being the first to introduce the syrup in this way, for field work, in your last leader, and I may say I have never found it fail in its intended purpose.—Yours truly,

Swansea. THOS. GULLIVER.

IMPROVED PLATE RACKS.

To the Editor.

Sir,—The suggestion by your correspondent "Ajax," in your publication of the 15th May, is not quite new. I have a machine for cutting the grooves for plate boxes of the shape described, and find it much approved of. Enclosed is a sample.—Yours, &c.

June 24, 1859. H. FRANCIS.

PATENTS CONNECTED WITH PHOTOGRAPHY, &c.

To the Editor.

Sir,—In reference to the remarks in the first leading article of the number for the 15th inst., as to the subject referred to in Mr. Rejlander's letter, allow me to suggest as a remedy in some degree for the evil complained of, that a statement be from time to time set out in your Journal of all inventions (deemed as such), in any specification of a patent relating to photographic affairs, or of the apparatus and chemicals used therein, with a request to your readers for information whether any such invention had been previously in use.

My own impression is, that except as to apparatus, it would be very difficult to secure a patent right for any improvement or invention relating to photography, and much more difficult to obtain evidence of a breach of such right from what is done in the mysterious gloom of the operating room.

For the guidance of your younger photographers, I have to suggest the use of a piece of gutta percha, made into the shape of a spout, being fastened to the necks of the bottles containing the developing and fixing solutions, by which means glasses can be dispensed with (except in the negative process), and also the use of an old metal teapot, with a piece of gutta percha tubing fastened round the spout of it, the outward-end of tubing being compressed into a longitudinal slit, as a washing utensil.

London, 16th June, 1859. I am, yours, &c. J. P. H.

[Unfortunately it does not appear at all difficult to obtain letters patent for almost any alleged invention or improvement in photography; and although but few of them would probably stand the test of a legal inquiry, that does not prevent the holders of said letters patent from taking or *threatening* legal proceedings against those who practice or use the alleged invention. This is precisely the wrong for which we desire a remedy; but to attain this it requires more than the influence of an individual.

It is not easy to procure particulars of any matter for which a patent is sought, except at certain very limited times, and then only with considerable trouble. It is a subject that has engaged much of our attention, and we have been endeavouring for some time past to organise a regular supervision, but without success hitherto.—Ed.]

ANSWERS TO CORRESPONDENTS.

T. Turnbull.—Wash with common filtered water, and then just cover the plate with distilled water before draining.

Querist.—1. Wet collodion. 2. Pyrogallic. 3. Must be saturated—coat or plate immerse, and leave it in all night.

Amicus.—We shall be happy to assist you if you send particulars, simply saying you "do not succeed" is not enough.

We are obliged for your kind offer, but we never hardly get within some miles of your locality; it would take us an hour and a-half to get home, even if fortunate in a conveyance.

Veritas, &c.—We are sorry to be obliged to decline a private reply—our time will not permit. Collodion of a fluid, contractile, and horny character, is what you require. Collodio-albumen is not good for the purpose—a moist plate being best.

Your want of definition is most likely due either to an inferior lens or faulty focussing. Depth of shadow and clearness in the lights are not to be had if you *over-expose.*

H. Dean (Exeter).—We always employ chloride of lime for removing stains of nitrate of silver from the hands: it is not so efficacious if the nitrate has become converted into hyposulphite, but we have frequently removed even the latter by continued application of the chloride of lime.

Chronos.—Your best plan will be to adopt that suggested by Mr. Lyte. Make a solution of pyrogallic acid one ounce, in alcohol four ounces. Four minims (drops) of this solution represent one grain of dry pyrogallic acid. If the alcohol be pure and concentrated, the solution will keep any length of time.

Anhydrous Alcohol.—R. W. S. can obtain alcohol in a very high state of concentration, by filling a bladder with it, and suspending it, securely tied, in the sun, or in a warm room. The water gradually passes through the membrane, leaving the alcohol in a more concentrated state. Alcohol will not moisten bladder, and, consequently, does not permeate it. To those who do not possess the appliances of a laboratory, this simple method of obtaining concentrated alcohol is invaluable.

Received.—"Photographic Negative Processes," "Smith and Beck," "J. B.," "James," "O. G. R." and "T. Marson."

THE PHOTOGRAPHIC JOURNAL.

No. 98, Vol. VI. — JULY 15, 1859.

Amongst the various pursuits that may be regarded as rather "up-hill work," photography in hot weather may certainly take its place. Not only are the incumbrances doubly heavy, the dark rooms or substitutes doubly stifling, but, worse than all, the chemicals, like spoilt children, are doubly troublesome, and just at a time, too, when you wish them to be upon their best behaviour. Of course one philosophises and invokes patience — prepares a plate with infinite care — in short does every thing most scrupulously *en régle*, only to find a foggy landscape, or a sitter's face the exact counterpart of mottled soap, as results. Such, at least, are the statements that reach us from several worthy correspondents, who appear to have exhausted all their known remedies, and tired out the patience of photographic friends by their clamorous demands for help. One writer piteously remarks that he has converted a friend into a bitter enemy by his unsuccessful attempts to procure aid, for the said friend being an amateur of *stupendous* reputation as a photographer, of whom it has been the custom to remark, when any unusually stubborn difficulty has arisen, "Oh! ask A about it; he'll be sure to get you out of it!" but lo! even he has no remedy for hot weather, and, worse than all, the faith of his followers has been shaken, the throne is in a tottering condition, and its occupant visits upon our correspondent's unhappy head the penalty due to a convicted rebel: hence it arises that we are now the recipient of this "tale of sorrow," not so much in the hope of our "being able to administer relief as to afford at least our sympathy."

We have, however, really so many complaints upon the same subject — difficulties from temperature — that instead of replying in our "Answers to Correspondents" to half the letters of the alphabet, "Constant Readers," "Photos in Fixes," &c., we prefer to discuss the matter here for general reference.

It must be borne in mind that, *as a rule*, chemical action is exalted in proportion to the elevation of temperature, while in some cases re-actions of a very energetic character become totally arrested as temperature becomes reduced. We may adduce, by way of illustration, the phenomena of fermentation and decomposition. Is it then surprising that the operations, necessarily of a delicate nature, upon which photography is altogether dependent should, in like manner, be subject to derangement?

The various ingredients employed by the photographer are each intended to play a special and definite part *under certain conditions*, one force being restrained by another until such time as it is possible for it to perform effectively under those conditions. If then the conditions be altered (in our case a given range of temperature), the "balance of power" becomes disturbed, and we have nought but anarchy and confusion instead of harmony and order.

Let us consider now what are our difficulties. First, fogging of the plate in warm weather, whilst in temperate weather the same bath and chemicals yield satisfactory pictures. Now, supposing the bath to be neutral, or very slightly acid, the fogging generally arises from too small a quantity of acetic, citric, or other *restraining* acid in the developer. We call these vegetable acids restraining acids when thus applied, because, when present in sufficient quantity, they *restrain* the reducing action of the developing agent (probably by supplying oxygen), for a certain moderate amount of time, excepting where, under the influence of light, an amount of actinic force has been acquired sufficient to overcome this restrictive action, the amount varying with the temperature. When acetic acid is employed, which is a volatile substance, if the developing solution happen to have been mixed for some little time, in warm weather it soon parts with a portion by vaporisation. In any case, however, the quantity of restraining acid required is always more in hot than in cool weather.

Some photographers attempt to make a compensation by extra acidity of the nitrate bath, and certainly this proceeding will to some extent remedy the evil; but it is one that we can scarcely approve, because although the requisite force is supplied, it is not brought into play at the best moment, previously to which time it is positively detrimental. Nitric acid is most effective in removing fogginess, but unfortunately it also produces materially impaired aptitude for the reception of the actinic impression. Moreover, the nitrate bath then requires restoration to its neutral condition on a return of ordinary temperature. We are strongly of opinion that it is highly desirable to keep the nitrate of silver solution in as uniform a condition as possible. It cannot be denied, however, that under a very high temperature it is almost impossible to secure clear plates without the presence of a very minute quantity of free nitric acid, and when this is the case we much prefer to introduce it by means of a little *free iodine* in the collodion, which gives it just *where* we want it, and in manageable quantities *when* we require.

The sum of our argument then is as follows:—In hot weather double the quantity of the acetic or citric acid in your developing agent, and if you still get foggy negatives add a drop or two of weak solution of iodine in alcohol to your collodion, enough to tinge it of a pale yellow colour.

We now come to our second annoyance — a mottled appearance of the plates when removed from the sensitising bath. This we believe to be due to the unequal evaporation of the ether and alcohol from the collodion before immersion of the plate in the nitrate bath: we have frequently experienced this inconvenience personally, but have invariably found a remedy in the addition of a little strong alcohol to the collodion, and allowing a longer time for it to "set" before immersion of the plate in the bath.

In our last we took exception to the explanation proposed by that eminent French photographer, M. Davanne, of the singular phenomenon noticed by Mr. Young, in connection with collodio-albumen. In our present number we have amongst our correspondence a communication from Mr. Barber, in which attention is drawn to another point, also bearing upon the same subject, which merits consideration. Our special object in adverting to it here, however, is to protest against the assumption that the photographic image is simply metallic silver, as has been affirmed by the gentleman above alluded to, M. Davanne, in conjunction with another celebrated French photographer, M. Girard. The two last-named gentlemen have done much in the investigation of the nature and properties of the photographic image, as connected with paper positive proofs; and the report of their labours, as published by the French Photographic Society, has been perused by all scientific followers of our art with considerable satisfaction.

We have, from time to time, in these pages, given an abstract of their results, and we are by no means inclined to undervalue the importance of them. We should, however, have been better pleased if they had been more ready to acknowledge the discoveries of those who preceded them, instead of apparently ignoring facts that were established by some of our English brethren in their "report," and publishing observations as original, which were only corroborative of the conclusions of their predecessors.

Amongst all the theoretical points propounded, that of the *simply* metallic nature of the image is one which we find it impossible to acquiesce in, it not being in accordance either with some of the phenomena exhibited by certain chemical re-agents, or with the researches of our countryman and friend, Mr. Hardwich, who demonstrated most clearly and satisfactorily that the ordinary photographic image upon paper *consists of silver in combination with organic matter.*

The direct collodion positive upon glass resists, for a considerable space of time, the action of a weak solution of cyanide of potassium — this is not the case with a paper proof either sun-printed or developed. Again, if the image were formed of metallic silver only, it should be capable of amalgamating with mercury — which it is not. Now, although we do not insist upon these facts alone as absolutely conclusive against the metallic theory, they certainly are opposed to it, and that very strongly, as is also the objection suggested in our present number by Mr. Barber.

MM. Davanne and Girard are still prosecuting their researches, and doing so with care and skill. We perceive, by the official report of the last meeting of the French Photographic Society, that they have inquired into the cause of change of tone from the action of the various fixing agents usually employed, and have arrived at the conclusion that it arises from their more or less solvent action upon the size used in the manufacture of the paper, and that *a portion* of the image produced in the pressure frame being *composed of silver in combination therewith*, it is, as it were, broken up.

In proof of this supposition being correct they adduce the fact, that a positive picture subjected to the action of steam becomes reddened, in consequence of its dissolving out the starch or gelatine; but they give no reason whatever why the image should be *red*, provided nothing but metallic silver be left behind. We do not find this the case universally, or even generally, with negatives or positives on glass — why, then, should it be so upon paper? But farther — upon paper, whatever the fixing agent, the impression remaining after its action is universally *red* of some kind. Now, it may be only a coincidence possibly, but it certainly appears significant, that Mr. Hardwich has shown that gelatine, in contact with nitrate of silver, and exposed to the light, *produces an insoluble* RED *compound*, and, if we are not mistaken, the same has also been demonstrated with starch.

It appears to us, then, that there is no reason whatever for regarding the photographic image upon paper as other than a compound of silver and organic matter — nay more, we are convinced that, ere they have concluded their researches, these eminent chemists cannot fail to arrive at the same conclusion: in fact, we fancy we perceive that they have taken the first step in that direction, and are heartily glad of it; but we take the present opportunity of again putting it upon record, *that Mr. Hardwich was undeniably the first to establish the true constitution of the photographic image.*

AMONGST the many objects of interest to the microscopist, and which have excited the greatest amount of discussion relative to the true interpretation of their nature, are the various delicate lines or other elegant markings found upon the siliceous remains of some of the smaller *diatomaceæ*, an order of plants inhabiting both fresh and salt water, and which are many of them so minute as to be indistinguishable by the unassisted eye. As many thousands of these infinitesimally small organisms are frequently mounted upon a single miscroscopical slide, in a space less than a square inch in area, it is no easy matter, under the miscroscope even, to pick out some one particular specimen, the operation being very like that of "hunting for a needle in a cart-load of hay;" and if this be the case with the owner of the slide, who may be supposed to have some idea of the locality where he may first have met with his illustrious stranger, the search for it might be regarded as almost hopeless by one unacquainted with its position in the slide as well as its general aspect.

In order to obviate the difficulty, various ingenious schemes were contrived by sundry members of the Microscopical Society to register the *latitude* and *longitude*, so to speak, of any object. Many of these are perfectly efficacious, but that which presents the greatest facility as regards economy, certainty, and utility combined, is one in which photography offers the means of constructing the scale, uniformly and effectively, and for it we are indebted to the suggestion of Mr. Maltwood.

It consists in drawing accurately to scale a square composed of 2500 smaller squares (fifty in each row), each one having a siding of a quarter of an inch.

In each of these squares, figures, in the form of a fraction, are clearly written, thus $\frac{1}{1}$, $\frac{1}{2}$, $\frac{7}{9}$, $\frac{7}{10}$, $\frac{7}{11}$, &c., indicating the *longitude* and *latitude* of the square in which it is found. This mass of squares is then used as an original, to be reduced by photographic means from twelve-and-a-half inches to one inch square, and of course with the scale itself the figures are also reduced to microscopic dimensions.

By means of a stop on the microscope stage the *slide* and the *Finder* can always be made to take the same relative positions; and thus when an object is observed, the position of which it is desirable to register, we have only to replace it with the Finder, when, by looking through the instrument, the numbers indicating its position can be read off.

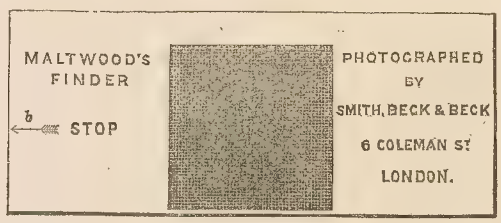
To find an object already registered, the converse of this operation takes place.

The following description of the instrument is that which Messrs. Smith, Beck, and Beck publish with it:—

MALTWOOD'S FINDER.

A "Finder," as applied to the Microscope, is the means of registering the position of any particular object in a slide, so that it may be referred to at a future time, and by any microscopist who possesses the Finder.

The subject has been fully discussed in the pages of the *Quarterly Journal of Microscopical Science*, and the best plan as yet proposed is that of Mr. Maltwood (see *Mic. Jour.* xxiii. p. 59).



It consists of a glass slide, 3 by $1\frac{1}{4}$ inches, with a scale (*a*) occupying one square inch, and consisting of 2500 squares, each of which is separately numbered with a longitude and latitude.

The scale is in each instance an exact distance from the bottom and left hand end of the glass slide, which when in use should rest upon the ledge of the stage of the microscope, and be pushed against a stop at the end; this stop, which is best as a simple pin, should be about one inch and a half from the centre of the stage, and at a point from the ledge as indicated upon the Finder at (*b*).

DIRECTIONS FOR USE.

The *object slide* must be placed under the microscope with the same care as the *Finder*, and when some particular *object* is in the field of view, remove the *object slide*, put the *Finder* in its place, and read the numbers of the square that comes in view; this may be recorded upon the *object slide*, and to refer to the same *object* at a future time, the process has only to be reversed by first finding the particular square of the *Finder*, and then by placing the *object slide* in its place.

We have taken great care to preserve an exact uniformity in the size of the scale and in its position on the slide, so that the registrations may avail any microscopist who possesses one of these Finders; we would at the same time mention that the ledges on the stages of microscopes are generally made at an angle, and when this angle varies, it may make a slight difference in the readings from the Finder, and principally on this account we have adhered to Mr. Maltwood's original size of fiftieths of an inch for the squares in the scale.

SMITH, BECK, & BECK, 6, Coleman Street, London.

May, 1859.

The experiments of MM. Monckhoven, Krafft, and others, upon the ammoniacal solution of copper, discovered by Schweitzer to be a solvent of cellulose, with a view to its application in photography, reminds us of another possible substitute. A corresponding ammoniacal solution of nickel has also been shown as a solvent of silk; but of this latter substance there is a simpler solvent readily accessible to all, and which may possibly be made available — we mean sulphuric acid. We must admit, however, that neither of them, ammonia or the acid named, are particularly desirable substances to deal with in the hands of novices. We have made no experiments in connection with the subject; we simply know the fact, that silk is soluble in sulphuric acid, and throw out the suggestion to those experimenting in this direction.

We learn from the *American Journal of Photography* that the number of members of the Photographical Society now exceeds one hundred, and as it has only been organised some four or five months as yet, we think the promoters have to be congratulated upon their success. At the fifth meeting, which took place on the 13th ult., Mr. Seely proposed the name of Mr. T. F. Hardwich for election as an honorary member, coupled with some well-deserved and graceful complimentary observations. The nomination was seconded by acclamation, and unanimously approved.

Such an act as that above recorded is regarded as a compliment by English photographers generally, and it does much to promote sympathy and good feeling. Before the close of the meeting, it was also

Resolved —"That the Corresponding Secretary be instructed to address letters of compliment to the Photographic Societies of London and Paris, assuring them of our desire to co-operate with them in the advancement of the art of photography."

In discussing the proceedings of a Foreign Society it is difficult to divest one's remarks of an appearance of national jealousy; feelings of patriotism will more or less make themselves visible when least intended. In any of the observations that we may make, we wish it to be distinctly understood that we shall endeavour to ignore nationality in photography, and adopt cosmopolitan principles. We must make remarks; we trust that they will be received only as intended — for the purpose of furthering our art.

We notice in the organ already quoted, that Dr. Draper has been making an attempt to supply that photographic desideratum, an "Actinometer," by employing for the purpose a solution of per-oxalate of iron, which, after insolation, reduces gold from a solution in direct proportion to the amount of actinic influence to which it has been subjected.

This application is the same in principle as that suggested by Mr. Fowler, of Leeds, at the meeting of the British Association for the Advancement of Science last year: a mixture of solutions of per-chloride of mercury and oxalate of ammonia were employed, which under the influence of light are converted into carbonic acid, which is set free, and photo-chloride of mercury (calomel), which falls as a white powder.

Dr. Draper's arrangement would not appear to be quite so economical as Mr. Fowler's; but if it be more certain or more sensitive, it may possibly, notwithstanding this drawback, be adopted in preference. The subject is one of great importance, and any who devote themselves to the solution of the problem deserve the thanks of photographers generally.

We perceive that the editor of *Cosmos* will persist in declaring that M. Saint Victor's statement of the property supposed by him to exist in tartaric acid of "storing up" light is incontestible, notwithstanding the startling evidence to the contrary that has been adduced—or rather, we should say, the evidence of the fallacy of the points upon which M. Saint Victor relies, for it is difficult to prove a negative. We quote the assertion:—"Tartaric acid, like nitrate of uranium, has, and it is at the present day an *incontestible fact*, the property of storing up light in its condition of activity and chemical efficacy." Such perseverance in a better cause would be invaluable; but when exerted in the promulgation of mere speculation as an ascertained fact, it is positively mischievous, and we shall not cease to utter a protest until the alleged fact can be satisfactorily proved. To quote from our predecessor, "pertinacity can only be met by the like."

EXPERIMENTS IN PARALLEL DIRECTIONS.

We have before now remarked upon the singular manner in which Mr. Hannaford has been treading in the footsteps of Mr. Burnett. It is perhaps fortunate that we happen to have been in confidential communication with both of these gentlemen, as we can testify to the *integrity of each of them as regards the other*, which we do most emphatically.

We say that Mr. Hannaford has been treading in Mr. Burnett's footsteps advisedly, because Mr. Burnett was at work long before Mr. Hannaford; and we find that the principle involved in the following process was actually communicated to us by Mr. Burnett, prior to Mr. Hannaford's so doing, but only by a few hours. In short, having carefully examined and compared our records we can positively affirm, that unless these two gentlemen had been in direct communication with one another, we do not see how it would be possible for either to have built upon the foundations laid by the other.

Instead of noticing, under the head of "New Books," a pamphlet which we received about four weeks back, we do so here, as it plays a part in the following. We must however premise, that more or less of its substance we had *previously* received in writing from the author.

Our readers may judge of our astonishment and indignation at receiving by post an imperfect copy of the pamphlet, but purporting to be written by an American, one John Brown, of New York, containing matter which we knew to be Mr. Burnett's, and couched in language and style unmistakeably his. This turned out to be Mr. Burnett's own doing, for a reason we may touch upon in a future number. For the present we will be content to give the preface to the pamphlet, then a paper of Mr. Hannaford's, and thirdly, a letter from the same gentleman — all being full of interest.

Photographic Negative Processes on Waxed and Plain Papers and on Glass. Specimen—Formulæ, and Remarks, by C. J. Burnett. London: John Sanford, 18, Red Lion Square. Edinburgh: Colin Sinclair, 69, George Street.

PREFACE.

The processes described in this pamphlet are founded on a variety of investigations and experiments made in 1854, and at intervals up to last winter. The first copies were struck off in a hurry, but it has now been revised, and some remarks, which in the hurry of abridgement had been cut short or misplaced, have been inserted in their proper places.

To prevent misunderstanding as to the nature of the processes, I will here roughly and broadly state (without going farther than photographers will care for) some of the outside principles on which my attempts at improvement are based —

1. That our sensitive papers [or films?] must contain at once two different classes of silver compounds; the first class being a compound of silver itself with iodine, bromine, or chlorine; and the second class being either silver-oxide or a compound of it with some acid—this latter class being, in our ordinary papers, represented by the nitrate of silver-oxide, commonly for briefness called nitrate of silver.

2. That while the salt employed to form our sensitising bath must necessarily and of course be a soluble one like the nitrate, it is by no means essential that the salt of the same (*i.e.* the second) class, to be left in the paper or films when ready for exposure, should be a soluble one, any more than that the iodide of silver or other salt of the first class should be soluble; but on the contrary, it is on many grounds infinitely better that it also should be an insoluble one.

3. That this desired substitution of the insoluble salt of silver-oxide for the soluble one is readily attainable by associating with the alkaline (or cadmic) iodide used in paper or film-salting the soluble salt of some acid whose compound with silver-oxide is an insoluble one, then after sensitising as usual, washing away the free nitrate (along with the soluble decomposition-products), so as to leave in the paper when ready nothing but silver-iodide and silver-bromide in combination with the tartrate, *oxalate, phosphate, fumarate,* or other insoluble salt of silver-oxide. Formula 2 is especially recommended, because the oxalate of ammonia is in most places kept for sale, and because, in default of fumaric acid or one of its salts, the oxalate of silver-oxide shares to a considerable extent the valuable property possessed by the fumarate (and phosphate) of insolubility in other organic acids; so that should we wish to add a little citric, tartaric, or acetic acid to our nitrate of silver bath, or to the washing water, or to the water used in remoistening before exposure, or to a solution of gallic acid or other reducing agent used in super-sensitising, we can do so without dissolving out or setting adrift any portion of the silver-oxide contained in the paper. The addition of a little acid (citric, tartaric, acetic, malic, or one of their *bi*-salts), to the *last* of the waters used in washing, seems advisable as tending to make the papers keep better, the previous waters having removed, along with the other soluble matters, any acid which had been taken upon from the sensitising bath. While alluding, in passing, to experiments with neutral and alkaline baths, it must be distinctly understood that I do not warrant my processes to succeed without, or with less than, the full usual quantity of acetic acid, or a *corresponding* quantity of the other acids named, either in the silver bath or in the last washing water, or in both, as well as in the developing baths or solutions.*

Edinburgh, 16*th June*, 1859.

SENSITIVE DRY COLLODION PROCESS.

By Michael Hannaford.

By the following manipulation extremely sensitive dry or preserved plates may be produced.

Make a saturated solution of chloride of ammonium, or chloride of sodium, and filter. Common table salt is quite pure enough for the purpose; or take citric acid, a quarter of a pound dissolved in half a pint of water, and add carbonate of soda until the solution is neutralised. Either of these may best be used as a dipping bath.

If great sensitiveness is the object, both the nitrate of silver bath and the collodion should be the same as will produce the quickest effects in the wet process — neutral bath and new collodion.

Sensitise in the usual way, and *slightly* wash — say, for a stereoscopic plate pour on a quarter of an ounce of water, and gently agitate until greasiness disappears. Well drain, and immerse in the chloride or citrate bath. After a minute or two remove, and wash with a large quantity of water. All the free soluble nitrate of silver is now converted into insoluble chloride or citrate, as the case may be. Any of the preservative solutions may now be employed: washed albumen, gum, or gelatine, &c., for dry plates; and honey or oxymel for preserved plates. I prefer the last two named.

The developer may be either gallic acid, pyrogallic acid, or iron. With some samples of collodion, particularly if new, a difficulty may be experienced in gaining intensity. I usually push the development as far as I well can, then fix with hyposulphite of soda, after which there will be found much less difficulty in getting the desired depth. With collodions commonly employed in the dry processes this inconvenience does not occur, especially when using the citrate bath.

Instead of converting the free nitrate of silver into chloride or citrate, it may be precipitated as bromide, acetate, oxalate, &c., but the above is the process in its simplest form.

I find that within a given time as nearly as possible the same number of plates may be prepared as by the Fothergill process.

London, 7th July, 1859.

Dear Sir,—I sent you this morning a short account of the preservative process I promised. It is, as you will see, the same in principle as I gave you at the meeting of the North London. I have said little or nothing of its comparative sensitiveness, for I am engaged in a series of experiments to ascertain that. I used citrate of soda to precipitate the free silver some time before anything had been said about mixing a chloride with albumen in Fothergill's process, but I never tried any other salt before then. The citrate is my favourite bath, but the chloride is cheaper and more easily made. The chief advantage I consider I have derived is, that I can get such sensitive plates by the use of oxymel, and that honey plates will keep so much better than when there is free nitrate. I have not, however, had so much practice with the honey as with oxymel.

You say that my experiments run very parallel with those of Mr. Burnett again.

I have been looking over his recent communications to you, and can only find a hint in the last number of the Journal, that he purposes giving some information on the use of insoluble salts of silver in the way I name, both on glass and *paper*. The same principle applied to paper would naturally suggest itself, and I have been experimenting in that direction with some promising results: so I shall look forward to Mr. B's communication with interest.

The idea of precipitating the free nitrate on paper prepared for positive printing, which perhaps you may remember I suggested to you at the last meeting of the North London Association, appears also to have struck him. You thought that the result would not compensate for the extra trouble. I have not had time to put the suggestion to any test, but I think it very likely you may be correct. The papers, however, might keep better. I shall try it.

The editor of a contemporary purposes giving us an instantaneous dry process. I have prepared my bath and collodion for it, and have only to get the palladium to commence; for there can be but little difficulty in guessing what it is, viz.—collodion (alcoholic of course), to contain two parts of an iodide and one of a bromide; bath acidified by nitric acid; developer, protosulphate and protonitrate of iron, with nitric acid; the resulting picture to be very weak, but full of detail; and intensity to be given by palladium. There is, I think, sufficient that is promising in it to make it worth a trial. I shall employ honey or oxymel for the preservative, which Mr. —— will *not* do.

I have been trying some experiments with a view to engraving on copper and steel, and the result is more than promising and very interesting.

I have to thank you for your information respecting the preparation of honey syrup, and am, yours truly, MICHAEL HANNAFORD.

ON THE ACTION OF POTASH ON GUN-COTTON.

By Edward Ash Hadow,

Demonstrator of Chemistry in King's College, London.

[In consequence of the interest attaching to the remarks made by Mr. Williams, at a recent meeting of the Photographic Society, relative to the presence of oxalic acid in collodion, Mr. Hadow, whose valuable researches upon gun-cotton, published in one of the early numbers of the *Journal of the Photographic Society*, are universally regarded as the "base of operations" for those engaged in similar investigations, has kindly acceded to our request of recording the following important facts from his own personal experience: —]

I made a few experiments some time ago on the action of potash on gun cotton, but I am sorry to say that they were at the time but imperfect, nor have I since continued them; but such as they were I have now much pleasure in communicating them.

Gun-cotton, as is well known, dissolves perfectly in a strong solution of potash, and the resulting liquid was applied some years ago by M. Vohl to the silvering of glass. This operation was effected by adding a little nitrate of silver to the potash solution, then enough ammonia to redissolve the precipitated oxide, and afterwards gently warming the liquid, when a mirror-like deposit of metallic silver takes place on the sides of the vessel in which the experiment is performed. It was partly from this property of the potash solution, and partly from a hope of getting an insight into the state of combination in which nitrogen exists in gun-cotton, that I felt the subject to be interesting. In a concentrated *aqueous* solution of potash at ordinary temperatures, gun-cotton dissolves slowly, but rapidly at 150°, the temperature then rising with each addition of fresh gun-cotton, and soon attaining the boiling point. With an *alcoholic* solution of potash the gun-cotton dissolves rapidly at ordinary temperatures, the solution separating into two layers, a pale alcoholic one above and a dark treacly layer below; in both cases a smell of ammonia may be plainly perceived, though the quantity is really very small.

* To any one having the slightest acquaintance with chemistry, it must be sufficiently obvious that the *introduction* of the *neutral* salts of the vegetable or other acids is not intended to supersede the ordinary addition of a free acid as employed to make the paper keep or to keep the pictures clean; still, for the benefit of those who ignore chemistry, it would appear to be necessary to be thus explicit.

On supersaturating the solution of gun-cotton in aqueous potash, or the upper layer of the alcoholic potash solution, with acetic acid, and testing a portion with a protosalt of iron, an intense blackening of the liquid occurs, showing that *nitrites* are present, and after expelling nitr*ous* acid by boiling with acetic acid, the liquid is found to contain nitr*ic* acid. Supposing gun-cotton to contain NO_4, this reaction with potash may be thus explained:—

$$2NO_4 + 2KO = KONO_5 + KONO_3.$$

When an alcoholic solution of potash is used, these two salts being soluble in alcohol, are present in the upper layer and crystallise out after a time.

The elements of the cotton exist in the liquid in the form of an acid, in combination with potash, and this compound being insoluble in alcohol, forms the dark layer which separates when alcoholic potash is used.

To isolate this acid the potash solution was neutralised with acetic acid, and mixed with a solution of acetate of lead. An abundant precipitate was thus formed, which was collected on a filter and well washed. It consisted of the acid in combination with oxide of lead, which latter was removed by diffusing the precipitate through water and transmitting sulphureted hydrogen. The lead being thus separated as sulphuret, was removed by filtering, and the filtered liquid, of a pale yellow, contained the peculiar acid to which the reducing action of the potash solution of gun-cotton appears to be due.

Several attempts were made to obtain crystallisable salts with this acid, but without success. With the ammonia salt indeed there appeared to be a promise of success, for after putting aside the solution for some days prismatic crystals made their appearance; but these on examination proved to be oxalate of ammonia, and after separating them only gummy masses could be obtained. Oxalic acid having thus been found in the liquid, it was removed, and the purified acid solution was set aside for some months in a bottle, labelled "free from oxalic acid." At the end of that time, however, when re-examined, *abundance of oxalic acid was found*, thus showing the strong tendency that this peculiar acid has to change into oxalic acid. The original solution of gun-cotton in potash also contains a portion of oxalic acid.

The unnamed acid above referred to presents some resemblance to saccharic acid, both in its relation to oxalic acid and in some of its re-actions; for, as saccharic acid is an intermediate compound between *sugar* and the ultimate product of its oxidation, oxalic acid, so the new acid is intermediate between *cotton* and the oxalic acid which is finally produced by oxidating influences upon it.

The sources, sugar and cotton, are closely similar in chemical composition, and the two acids resemble each other in their property of reducing salts of silver to mirror-like deposits, and in precipitating salts of baryta, lime, and cadmium; the crystallisability of the saccharates however presents a marked difference between the two.

These experiments were made with the most explosive variety of gun-cotton. How far the other varieties of gun-cotton would yield similar products with potash depends upon the degree to which the NO_4 in these compounds is concerned in producing the *reducing* acid with the elements of cotton. If, as appears probable, the weakest variety of gun-cotton contains sufficient NO_4 to form the acid with the elements of cotton, all the varieties of gun-cotton would yield the same products with potash, the only difference being in the amount of nitrite and nitrate formed at the same time. Upon this point I am unable to speak from actual experiment.

METHOD OF OBTAINING PURE WHITES IN DIRECT POSITIVES.

By MM. Davanne and Jöuet.

Direct positives do not always exhibit the pure silvery white that operators desire; the colour being often ashy or ochreous, to the great detriment of the picture. In some experiments we have obtained proofs which appeared more brilliant than most of those generally seen. Our process, however, can boast of nothing new: it consists in the addition of a certain quantity of sulphuric acid to the iron developer, which enters into a host of formulæ already given; and if we have had better results, it is due to our employing, instead of an empirical formula, one based upon the elementary laws of chemistry.

To obtain a brilliant metallic white, it is necessary that the molecules of silver, which are deposited and form the image, be as pure as possible; we must, therefore, inquire what takes place when we develope a picture.

The oxide of silver in the nitrate is decomposed by the sulphate of the protoxide of iron, and while the silver is reduced to the metallic state, the sulphate of the protoxide passes to the state of sulphate of peroxide. But the sulphate of the peroxide of iron thus formed is basic and insoluble: it envelopes, as it were, the molecules of silver deposited at the same time with it, and communicates to the silver an ochreous tint. Instead of the insoluble basic peroxide of iron we ought to obtain the neutral sulphate, which is soluble in water; but this is formed only when we add to the iron solution a certain quantity of sulphuric acid. The quantity necessary to produce a brilliant silver is easily determined by the following formula, which exhibits all the phases of the operation:—

$$2\,Fe\,O,\,S\,O_3 + Ag\,O,\,N\,O^5 = Ag + N\,O^5 + Fe^2\,O^3,\,2\,S\,O_3.$$

The composition of the soluble sulphate of peroxide of iron being $Fe^2\,O^3,\,3\,S\,O_3$, we see that we must add one equivalent of sulphuric acid for two equivalents of sulphate of protoxide of iron, or in weight 6.12 gr. of sulphuric acid for 26.87 gr. of crystallised sulphate of protoxide of iron.

In practice, and to have round numbers, we may say in general terms that the quantity of sulphuric acid must be equal to one-fourth of the weight of sulphate of protoxide of iron. The following formula may be given:—

Water	12	ounces.
Alcohol	5	"
Acetic acid	5	"
Sulphate of protoxide of iron, in crystals	4	"
Sulphuric acid (by weight)	1	ounce, or

By measure, 0.58 ounce.

GOLD TONING BATH MERITING FURTHER TRIAL.

By C. J. Burnett.

Make a good strong terchloride of gold bath, and then add to it first common salt, five to ten grains per ounce, and then carbonate of soda first till litmus paper is turned blue, and then, if wished, as much more again. The chloride of sodium prevents precipitation of gold, even when kept long. Carbonate of potash may be substituted for soda, and chloride of potassium or bromide of potassium (or fluoride ?) for common salt. Iodo-aurate and bromo-aurate of potassium are reduced by silver, and appear not unlikely to be useful in toning. The latter at all events is safe enough. The solutions of gold in cyanides, ferro-cyanides, and ferrid-cyanides, and their allies also merit a trial; also similar solutions of platinum and palladium.

I recommend the substitution of the double chloro-aurate or bromo-aurate of sodium or potassium for the terchloride of gold, as being nondeliquescent, a great point of convenience as to keeping and weighing.

It is an ascertained fact that chloride of sodium has an affinity for the *aurate of soda* which is formed of the free alkali, and that its presence in the bath in *considerable* quantity is therefore advantageous in preventing precipitation of gold or auric oxide. I can only add that if any one will try the experiment, I think he will be satisfied that the fact is as I have stated. I believe that even a LARGER quantity than I gave you of chloride of sodium may be of advantage, lessening still further the liability to *spontaneous* precipitation of gold.

POSITIVE PRINTING WITHOUT SALTS OF SILVER.

By M. Poitevin.

Light acts chemically upon a great many compounds, even upon those which have not yet been the subject of experiment, to make them pass into a lower state of oxidation, that is to say, to eliminate one of the electro-negative elements they contain.

This paper will be confined to describing a photographic process resulting from the action indicated, which enables us to obtain positive proofs upon paper in which gallate of iron (writing ink) is the only colouring agent.

Make two separate solutions, the one of perchloride of iron, ten grains to one hundred of water; the other of nitrate of uranium, of the same strength (10 per cent.), mix the two solutions in equal proportions. Take some good thin photographic paper and float it on the smoothest side for a few seconds upon water. When drained,

lay the dry side upon a glass plate or piece of wood, the dimensions of which are a little less than those of the paper, then cover the moistened surface equally with the mixed solutions, and pour off the excess into a bottle. The mixture may be kept several days in a black bottle without alteration.

The paper thus prepared is dried spontaneously in a dark place. It appears of a deep yellow colour. It must be put into a printing-frame under the design it is desired to produce. This design must be *positive*, for the parts of the paper thus prepared influenced by light are white. A waxed positive may also be employed. The exposure under a positive *cliché* is from fifteen to twenty minutes in the sunshine, it varies according to the intensity of the *cliché;* the necessary amount of exposure can be estimated by the colour of the prepared paper, the intense yellow of which becomes white under the influence of light; this decolouration must penetrate the paper. The decoloured portion is formed of perchloride of iron brought to the state of protochloride, which does not become coloured under the influence of the gallic acid employed for developing the picture.

To obtain the design in black, moisten the paper with water as in the previous instance, let it drain, then lay it on a glass plate or piece of wood, and pour over it a saturated solution of gallic acid, or of pyrogallic acid of the strength of two per cent., or even a concentrated infusion of nut galls will serve.

The gallic acid gives a violet colour to those parts of the image in which the perchloride of iron is not decomposed.

Pyrogalic acid gives a lead-grey colour to the same.

A mixture of these two acids gives an intermediate colour which may be varied by altering the proportions of each.

To fix the proof, it is washed in ordinary water renewed once or twice, then sponge the surface and leave it to dry. The colour becomes more intense in drying. Proofs thus obtained are as unchangeable in the atmosphere as ordinary writing; the materials are inexpensive.

The process is therefore cheap and safe.

NOTES OF A PHOTOGRAPHIC TOUR IN THE HOLY LAND.

Upon one of those warm sunny days which, during the ides of March, deluded us with the idea that spring has stolen a march upon winter, I found myself seated at a little table outside a *café* in the *Boulevard Italien*, sipping a miserable compound of Martinique coffee and chicory, which is extolled as a model for imitation to the barbarians across the channel. I was deep in study in the *feuilleton* of *La Presse*, and just beginning to unravel the thread of the mystery of a tale, when a heavy hand fell upon my shoulder with a weight and a grip that I knew could only be inflicted by a Lancashire man. "Halloa, parson! I want you; going across the desert, and you must come too: I want you to take Jerusalem and Damascus, so pack up your traps and come along!" Such an address awoke in my mind a strange confusion of ideas. Desert! Jerusalem! Traps! I looked up and saw the broad honest face of my college chum, Weston.

John Weston is in every sense of the word a strong man: strong in his Herculean frame, strong in will, firm of purpose. Whatever John says you feel must and will be done. I saw at once that I must cross the desert with him; and, had the next day been fixed for my wedding, it must have been postponed, for John is one that takes no denial, so I meekly replied: "When do you go? When must I be ready?" "To-morrow. To-day if you like, so look alive!" I had only to say, very well, and then bethink me of what was necessary to be done before starting. John informed that I was to consider only my own *personne*, that he would provide all things needful for the offensive and defensive, revolvers included; so having despatched a note to my *blanchisseuse*, I proceeded at once to provide myself with a good supply of waxed-paper and the requisite chemicals. Taking a bellows-camera, my whole photographic baggage was comprised within the compass of an ordinary writing desk, and before sunset I was in complete marching order. At six o'clock next morning we were on the Lyons railway, *en route* for Marseilles. I said *we*, but I have not yet said who *we* were. Besides John and myself, already mentioned, our party consisted of an American gentleman and lady, who, acquainted with John, and having unlimited confidence in his valour and resources, had placed themselves under his guidance and protection.

I had always looked up to John: a brave, hearty fellow, who seemed born to protect the weak, to conquer difficulties, and overcome menacing dangers. I do not think I would have trusted myself on so perilous a journey in any other person's company than his, for I felt sure that whatever scrapes we might fall into he would get us safely out of them; and, as I have no doubt will be shown in the sequel, my confidence was not misplaced.

As each member of our party studied to be agreeable to the other, our journey was as pleasant as could well be imagined; but as nothing of more than ordinary interest occurred, I shall at once jump to our arrival at Gaza. I must not, however, omit to remark that as I was strolling through the streets of Marseilles, I stopped before the shop window of a bookseller, and there to my great surprise and delight I saw a copy of The Photographic Journal, dated March 15th. It was like meeting an old friend. I walked into the shop, and entering into conversation with the *libraire*, I found he was an amateur photographer. Bringing forth his portfolio, he showed me many interesting views he had taken of the public buildings, Roman antiquities, &c., of his city. He was a subscriber to your Journal and to some others, but he gave unhesitatingly his preference to yours, for, as he said, he was sure to find in it *la science* and always *du nouveau*. * * * * * * * * *

Well, here I am encamped on the plain that lies between Gaza and El Arish, in a hollow, from whence, all night long, I can hear the heavy *thud* of the surf on the shore, beating that solemn, steadfast time-beat that has shaken the desert hills for who knows how many thousand years. It is dawn; the morn is coming up like a giant refreshed. There is a glow in the horizon, succeeded by a burst of splendour, and up in the sky soars the golden sun, monarch of all he surveys. Swiftly shrink the long shadows of the sand-hills into dark spots in hollows, and soon a rich light, such a light as can be felt, lay upon all the desert.

In such scenes as this how the whole man expands! You seem to grow with every breath you inhale. All the past is yours, you feel yourself its representative, its living embodiment. And yet you feel humble withal: humbled at the reflection, which on such a spot as this becomes a sad conviction, that indeed all is vanity.

This is the fourteenth day since we left Cairo. My outward man is changed into something more in harmony with the scene around me, and I feel the inner man changing too, more than I could have dreamed. I feel myself insensibly acquiring the tone and manners of the strangers whose land I have invaded. Collodion and hypo' seem strangely out of place here, and I could not help smiling when one day I suddenly found myself in front of a camera, planted by an enterprising Frenchman in the streets of Cairo.

But I was describing the morning on the desert. It will soon be left in our rear, for little hills and occasional groves of olive trees and the prickly pear are in view. We are passing the line of no rain! and entering the country where occasional showers insure a certain though feeble vegetation.

I am in the land of the Philistines. Before me is Gaza. How often, when a child, had I pictured to myself a giant striding up the hills on the east, on a dark night, bearing on his shoulders the rent gates of the city! But this I see is a modern city, with some five thousand inhabitants. "Gaza shall be forsaken." The mighty are fallen. Sampson is dust: the temple he threw down with the last struggle of his mighty soul is crumbled to ruin, and flowers grow and bees suck honey in the dust that was stronger than the lion of his own fable.

The sun was setting in the Mediterranean as we approached Gaza. John rode on in advance to select a spot for the tents, and I followed leisurely with the baggage. We form something of a caravan with our six horses and a file of half-a-dozen camels carrying tents, &c. About a dozen Bedouins flutter round us as escort, watching for *baksheesh* or plunder.

Our tented field was a burial ground, a fitting and curious place to sleep. At home I have no fear of ghosts, but who could sleep in a Moslem cemetery believing that the dead would lie quietly? I lay awake looking for them all night long, and so positive was I that I should see a ghost, that when Sheikh Selim lifted the tent curtain in the morning dawn, and put his thin, gaunt countenance and skinny hand into the opening, I rushed at him, to his total rout and overthrow, for he thought he had intruded, and sprung back to avoid an expected blow, stumbling over the cook, who was on his hands and knees blowing at his breakfast fire, and Selim, the cook, and the breakfast made a mass of ruin on the ground that resembled, though remotely, the ruins of Gaza.

So soon as my cook had recovered his equanimity, after this inglorious overthrow, to concoct his usual preparation of coffee and accessories, I made my breakfast, not without comparing the decoction of the Arabian berry with its poor substitute on the Boulevards. It is melancholy to reflect how many thousands of Europeans

go to their graves without having tasted in perfection—coffee! That bitter, mawkish, insipid decoction of chicory and beans so constantly foisted upon the ignorant for the fragrant berry, is no more to be compared to the latter than is champagne to toast and water. Coffee cannot be made and drunk too quickly; every moment it stands letting off its fragrant steam it loses its virtue, the true spirit evaporates, and what is left is but a *caput mortuum.*

I could fill many pages with the praises of coffee, of the coffee of the barbarians, not that of civilisation. No matter how exhausted or weary I feel in my travels, give me but a cup of the true Eastern beverage, and in a few moments "Richard's himself again!" Its restorative power on an exhausted frame is truly marvellous; but then it must be the pure, freshly-prepared infusion.

But here I sit dreamily gazing at Gaza, and John will want to take Gaza away with him, so I must needs plant my camera and set to work. About the modern city the ruins of the ancient lie engulphed around in broken columns and fragments of capitals, architraves, and friezes, all appropriated to the vilest uses. The mosques of the city are mostly built of the stone of the old ruins, and the muezzein calls the faithful to prayer within walls which have echoed the praises of Dagon. Half a mile away the hoarse surf thunders a mocking triumph over the decay of the grandeur of the oldest of cities: the stillness of its port, the wreck of its harbour, the absence of its merchants. How solemn the scene, now so desolate and lonesome, contrasted with what the mind conjures up when the port was crowded with its galleys and thronged with princes and merchants!

It was towards the cool of the evening that I took my first picture in Holy Land. The declining sun tinged with a golden hue all the features of the scene; the shadows were deep but not dark, giving a relief to objects such as I had never seen before. I brought away with me the forms of things it is true, but how I sighed for the magic colours that illumined the picture, no tongue but my own can tell. D. T.

Meetings of Societies.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

A MEETING of the above Society was held on the 20th ult.; the President, J. GLASHIER, Esq., F.R.S., in the chair.

After the usual business had been transacted, Messrs. Henry Kent, Newton Crossland, Thomas Skaife, and William Kieser, were duly elected members of the Society.

Mr. HEISCH exhibited two dry plates, one prepared by Hill Norris, the other by himself by the meta-gelatine process; both had been kept so long, that a dirty deposit formed during development. On the plate prepared by himself this was entirely removed by gentle friction with a pad of wet cotton; on attempting to do the same with Norris's plate, the whole picture came off in powder; but the point to which he called the attention of the Society was this, that the glass was still entirely covered with a transparent film. This film resisted the action of a mixture of ether and alcohol, but was removed at once by hot water; it was apparently a coat of gelatine. The question is, does Dr. Norris coat his plates with gelatine before collodionising, as has been lately so much recommended, or is his collodion so powdery as to let enough gelatine through to form this film? Mr. H thought the former supposition much the most probable. Mr. H also exhibited one of Derogy's lenses and the pictures taken with it, which were of the most satisfactory description.

Mr. T. R. WHEELER delivered a short paper upon Monckhoven's cellulose process, as recently employed by him; and exhibited a picture taken by it, as well as some prints from that picture. He adverted to the discovery by Schweitzer, of Zurich, that cotton and silk were soluble in cupro-ammonium, and to that of Pelouze as to the solubility of cotton in concentrated hydrochloric acid, and to the application of that discovery by Peligot, while Monckhoven, of Ghent, had collated what was previously known on the subject, so that the process was not unfairly named "Monckhoven's Process."

The author stated that the object of the several methods in which the ammoniacal solution of copper is employed is the same, viz.—to obtain the solution of oxide of copper in ammonia. Monckhoven's plan was to throw down hydrated oxide of copper from commercial sulphate by liquor potassæ, and dissolve it thus obtained in liquor ammoniæ. Peligot's plan amounted to the same thing, and was the one he (the author) employed.

It consisted in placing copper turnings in a funnel in which some pounded glass was put, and pouring liquid ammonia upon it. The air oxidised the copper, and the ammonia dissolved it as fast as formed. The solution, which should be passed and repassed through the copper turnings that it may be saturated with oxide of copper, is allowed to stand, that all impurities may subside, and is then decanted. Carded cotton is then introduced in the proportion of about two parts to every twenty of the solution; it readily forms a viscid solution, and that being complete, it is ready for use. Iodide of potassium is added, dissolved in water in the proportion of about two grains and a half to the ounce.

If well prepared, it is perfectly transparent, of a deep blue colour, and flows readily upon the surface of glass.

When employed as a photographic medium it is poured as a film like collodion, and allowed like it to set partially, which is known by a whitish opalescent margin appearing; this occurs, of course, at varying intervals, on account of the varying state of the temperature and its hygrometric condition, but an average time is half a minute; it is then immersed in a bath consisting of water one hundred parts; nitrate of silver, ten parts; acetic acid (glacial) five parts. A few seconds' immersion is sufficient. The surface of the film whitens, and should have a homogeneous texture. It is then exposed in the usual way, and, according to the author's experiments, requires rather a longer exposure than collodion, say thirty seconds. It is then developed. For this the author used—pyrogallic acid, one grain and a half; water, one ounce; acetic acid, ten minims; then washed and fixed with hyposulphite of soda. The picture obtained is in many respects a good one, and the process, generally speaking, one of much promise.

The advantages to be enumerated are, its great cheapness, its facility, its uniformity of composition, and the fact that commercial nitrate of silver may be employed for the bath; also its remaining moist in very hot weather, and that it may be kept in the air many seconds before immersion. It must not, however, be kept too long before immersion in the bath, or the ammonia volatilises. The principal disadvantage of the process—and it is that with which the author had mainly to contend with—is that the film is liable to become detached when immersed in the nitrate bath. It remains to be shown why this so frequently, and apparently so capriciously, occurs; the author believes it to be due to the energetic chemical action which takes place between the ammonia of the cotton solution and the acetic acid of the bath, which is required to be in excess to dissolve oxide of copper. He intends making experiments on the subject with a hope of obviating the difficulty, as also to employ the "cellulose" in a dry process. With respect to failure, those accustomed to chemical manipulations will easily understand how hard it is to pronounce wherein it lies, since much disappointment must be encountered, and much inductive experiment, used before success is attained. What becomes of the copper? The author believes that it, with the cotton in solution, acts as a base to a radicle in the first instance, and that the excess is removed by the acetic acid in the form of a diacetate. The author apologised for the hasty and imperfect manner in which his remarks were conveyed, but hoped to renew the subject with more effect and better success during the ensuing session.

At the conclusion a vote of thanks was tendered to Mr. Wheeler and the meeting separated.

PHOTOGRAPHIC SOCIETY OF SCOTLAND.—In our advertising columns will be found the list of prizes for photographs and for original communications to the Society, to be given during the forthcoming Session of 1859-60. We shall for the present simply direct attention to the advertisement.

DR. HILL NORRIS'S DRY PLATES.—A few day ago some plates were sent to an eminent Liverpool photographer with a request that they should be exposed two seconds. The writer saw two plates developed in three minutes that had been exposed on Tuesday evening last, at seven o'clock, five seconds—stereo., six-inch focus—and they were considerably overdone. This is a fact of the very highest possible importance to the photographic art, as instantaneous impressions on dry plates have been hitherto a great desideratum. Photographers owe Dr. Hill Norris a debt of gratitune already; and, should he publish his process, as he has done heretofore, he will confer a lasting obligation upon all connected with our art. The writer has lately been operating with gelatine and honey, and finds great acceleration; and he would earnestly advise his brother photographers to try in this direction, should Dr. Norris not favour us with his process.—*Communicated.*

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER III. (*Continued*).

ON COLOURS AS PIGMENTS.

OF RED PIGMENTS.

Red stands pre-eminent among pigments for power—is more nearly allied to the advancing than the retiring colours. Its effect is so great upon neighbouring hues and tints as to demand the exercise of the utmost skill in its use; it boldly challenges the two extremes of black and white to diminish its beauty; and never fails to convey to the mind sentiments associated with splendour and brilliancy. We have numerous red pigments.

Lakes—A variety of beautiful colours bear this name: they are prepared from several substances, viz.—Brazil wood, cochineal, lac, and the root of the madder plant, which last alone is permanent.

Crimson lake is of a rich deep colour and very fugitive; the *Scarlet lake* the same.

The lakes prepared from the madder plant are very beautiful, and are most commonly used for oil and water, although they have not sufficient power to serve all the painter's purposes.

Madder pink and *madder lake* are pigments of nearly the same character.

Carmine—A very beautiful colour, but very fugitive; works well in oil or in water.

Madder carmine—A beautiful and durable colour for water or oil.

Indian lake—The best member of the lake family, but not the most beautiful.

Vermilion—A very useful and beautiful pigment; works better in oil than in water, but is used for both; is opaque, of good body, and very brilliant. A *pure* preparation of this colour is, I believe, permanent, but it is very frequently contaminated by mixture. It is a sulphuret of mercury. The vermilions called scarlet and orange are best for water; that known by the name of *iodine* is not to be depended on for either, although of wondrous beauty.

Light and *Venetian reds*—Very valuable either for oil or water, and are quite permament; the former is burnt brown ochre, the latter a preparation of iron.

Indian red—A very rich iron ore, of a lakey tone, generally used both for oil and water, of good body, works well, and is perfectly permanent. It varies in hue but not to any important extent.

OF BLUE PIGMENTS.

Blue, among the primaries, represents shade, being by its qualities most nearly allied to black; it is representative of coldness, and contributes its characteristics to all its compounds. Blue pigments are not very numerous.

Ultramarine—A very brilliant permanent blue, nearly opaque, prepared from the lapis lazuli of Persia; it is not much used in consequence of its high price; its tints are very pure, its permanency undoubted; it works well in oil, but is managed with much difficulty in water, in which case a *little* gum* is usually added to it. For compounding hues ultramarine is unsurpassed, but all these qualities depend upon its purity, and, alas! like most other things it is too commonly adulterated. You may test it, however, thus: add a little piece of the pigment to lemon juice, when, if it be pure, its colour is instantly destroyed. There are several imitations of this colour prepared and sold at a very cheap rate; the most celebrated is called *French ultramarine*, which approaches the original in beauty and permanency; the acid test produces the same effect upon this blue as upon the original ultramarine, but *with effervescence.*

Cobalt approaches in brilliancy true ultramarine, but has less power; it is of good body, works well in water and oil, is nearly permanent when carefully prepared, and very pure, being neither greenish nor purplish; its greatest foe is impure air. (Blues called *smalt mineral* and *royal* are all cobalts). It is prepared with metallic cobalt or its oxides. Of these blues the "royal" is least permanent.

Prussian blue—A bright, deep, and very transparent blue, of great body and power, but not very pure or permanent; useful in water and oil, but liable to be destroyed by lime and alkalies; a capital colour with which to compound greens. A lighter preparation of this colour is called *Antwerp blue*. Prussian blue is produced by combining hydrocyanic acid, iron, and alumina.

Indigo—Prepared from plants in the Indies; not bright, but extremely transparent and powerful, of good body, and working well in oil and water; its durability has been disputed, but it is now generally called "fugitive." A preparation of indigo, called *Intense blue*, is the better pigment. Indigo is very generally used by painters of every description.

* Too much will destroy its brilliancy.

OF GREEN PIGMENTS.

A colour so common in nature, so refreshing to the eye, and so well beloved as to command the most frequent use for domestic and decorative purposes, is of all colours the most dangerous to a picture. Place a "green picture" beside a painting glowingly brilliant with the rich hues and colours of the warm scale, and we at once perceive this fact. The one *demands* notice, excites pleasurable sensations, and conveys a power which *commands* admiration; the other seems poor and mean in its unobstrusive and retiring nature, and all the attracting power it has is fiercely ravished from it by its powerful rival. It is only when the glowing hues which attracted each spectator's eager glance begin to weary the excited retina, that the beauty and utility of the calm and quiet "green picture" reaches the eye with all its cooling and soothing power and then acknowledged beauty, thus proving the importance of what artists denominate the balance of colour. We have a very large number and variety of green pigments, but greens are so frequently compounded by the artist that but few are on demand.

Emerald green—Metallic: the most bright and powerful of its tribe, and the most permanent; it works better in water than in oil; is too brilliant for common purposes, and is generally nsed for drapery and jewellery.

Hooker's greens—Bright but not quite permanent; very useful in water.

Verdigris—Acetate of copper: very fugitive in water but tolerably permanent in oil, especially if preserved from impure air and damp.

Terre-verte—A bluish-green earth, not very beautiful but very permanent; is never used in wter, but is a most useful pigment in oil.

Chrome green—A pigment compounded from chrome yellow, used in water with gum; not very powerful but quite permanent, works well in oil.

Olive green—A compound pigment eligible for oil or water; useful for backgrounds, &c.

[The following may act as a caution to professional photographers to be on their guard against a surreptitious use of their negatives, a proceeding that may involve them in very awkward predicaments. Negatives not in actual use had better be kept under lock and key.]

A Photographer's Assistant Charged with Embezzlement.—On Saturday, the 2nd instant, at the Liverpool Police Court, Bennett Lowe, a gentlemanly-dressed young man, was charged with having stolen photographic chemicals and prints, belonging to Mr. Keith, of Castle Street. Mr. Bluck appeared for the defence. The prosecutor said that he engaged the prisoner in October last, and treated him as a confidential servant, in which capacity he had access to the whole of the stock. Witness had frequently complained of the quantity of material which was used, and having on the previous day received a letter from a gentleman in Manchester, who stated that he had frequently purchased collodion from Mr. Lowe, as well as twenty-three photographs, he caused Lowe to be apprehended. He went down to Manchester and recognised the pictures, which he believed to have been made in his time and with his material. Witness was placed in a very peculiar position with regard to these pictures. The prisoner had the negatives in his care, and could therefore print as many as he liked. A great many gentlemen who came to sit for their likenesses would object to have them exposed; but when he went down to Manchester he found three or four of his pictures which he would not have dared to exhibit in Liverpool. He also found some photographs of Mr. Walter's paintings, which he was bound by contract not to sell or give away, except to Mr. Walters himself, who of course had a copyright. In reply to Mr. Bluck, Mr. Keith said he paid the prisoner 30s. a week. He did not think he had opportunities of doing them himself, and did not know whether Mr. Walters had given him the prints of the pictures. He could not swear to the collodion which was sold to Mr. Johnson, of Manchester, but he could swear to the bottle in which it was sold. The prisoner had left the witness's employ about six weeks, and was employed at Shrewsbury. Mr. Johnson proved that he had purchased the collodion and the prints from the prisoner. Mr. Bluck contended that there was no case made out, as the prosecutor could not swear to the property. The prisoner might have printed the pictures himself from the negative, and he was prepared to prove that he had purchased the collodion. Mr. Mansfield said that the case was more like an infringement of a right than anything else. If he had taken the negatives, no doubt he had committed a trespass, for which he might be sued, but he would not be guilty of a larceny. There appeared so much doubt about it, he thought it would be safer to dismiss the charge.

Letters to a Young Photographer.

No. XIV.

My dear Eusebius,

As the old song says — "I've locked up all my treasures," and as the song does *not* say — I've put the key in my pocket. I am not going to stay here, half roasted or baked alive, just to gratify you with writing letters. I am off "to fresh fields and pastures new," and shall expect to meet you at Wolverton Station, on Monday forenoon, in full marching order. I shall leave here by the first train. I do not intend to encumber myself with any photographic luggage, but will make use of yours, and shall expect to find every thing clean and in good working condition. I may bring with me a new tent, which is very roomy and portable; but have not yet decided upon even encumbering myself with that indispensable article, as you will have your dark box with you. I have got a nice patent knapsack, into which I have stowed away a couple of shirts, two pairs of socks, my old slippers, and an interesting volume. With this and my trusty sapling oak I am ready to make the circuit of the globe. With no greater encumbrance, except a stout pair of walking shoes, I made the tour of half of Europe, going over some six thousand miles in twenty months; that was before railways were much in vogue, and I feel as if I should like to do it again. The face of the world, as well as my own, has grown wrinkled since then. That journey done, I thought I had *done* the old world, and would hob-nob with the new, so I crossed the Atlantic, and my first daguerreotype picture was taken on a site famous in the annals of history, and dear to every lover of liberty, on Bunker Hill, near Boston, where our grand-dads fought and shed their blood in defence of noble principles.

But I am wandering from the point. I suppose if I ask you to bring every thing, you will leave behind something we cannot do without, so I must needs give you a list of the indispensables.

Item. Camera and lenses.

Do not carry the lenses in a green baize bag as many persons do, whereby they are extremely liable to become scratched or broken, but have a little box made to hold them, and pack them carefully in cotton wool.

Item. Tripod (folding).

Item. A portfolio, into the pockets of which you will put your prepared paper, carefully secured in an envelope.

Item. A veil of black merino, to cover the camera and head while focussing.

Item. Three gutta-percha dishes, fitting into each other, and three funnels, ditto ditto.

Item. A quire of blotting paper, some cut filtering paper, and some paper coloured yellow.

Item. A box of scales and weights.

Item. The box of chemicals, containing nitrate of silver, iodide of potassium, acetic acid, citric acid, gallic acid, and hyposulphite of soda.

Item. Graduated glass measure, two ounce.

Item. A silver hook, and three or four brushes.

Item. A pressure frame.

Item. Whalebone pincers, black pins, and ball of twine.

Item. A few ounces of 'bacca,' to coax the bumpkins with, and some pieces of ribbon, of various colours, whereby to win the suffrages of the rustic beauties.

If I have omitted anything, be the consequences on my own head. I intend that our operations shall be confined to turpentine-waxed-paper, which I described to you in my last; but as I want to test the value of another waxed-paper process on the present occasion, I wish you would prepare me some paper with *cereoline*, in the following manner: —

No. 1. Dissolve four ounces of white wax in eight ounces of alcohol, by boiling in a retort; attach the neck to a refrigerator, so as to recover the alcohol. When the solution is complete, put it away in a corked bottle to cool. As it cools, you will see certain solid substances appear, which are the components of wax insoluble in alcohol. The cereoline remains in solution, which may be separated from the solid matters by filtration through a piece of fine muslin, and afterwards through filtering paper, first adding to the solution the alcohol that has been distilled over. Keep the solution in a glass-stoppered bottle.

No. 2. Dissolve in three ounces of alcohol three drachms of iodide of potassium, ten grains of bromide of potassium, and ten grains of the fluoride of that salt.

No. 3. Put about ten grains of iodide of silver into a glass measure, and pour upon it, drop by drop, until it is all dissolved, a concentrated solution of cyanide of potassium. This is added to the solution No. 2, and well shaken. A large quantity of deposit falls to the bottom of the vessel, which consists of the bromides, iodides, &c., and which will serve to keep the alcohol constantly saturated.

You will prepare the negative paper by taking five ounces of the solution No. 1 and adding to it half an ounce of No. 2, carefully filtering the mixture in order to separate the crystals, which would produce spots on the paper. Pour it into a clean porcelain or glass dish, and immerse in it four or five sheets of paper, and let them remain a quarter of an hour; then take them out, drain, and suspend them to dry in a dark room; they will assume a rose-red hue. Preserve them from the air and dust in a portfolio.

The sensitising is performed in the usual manner; the proofs are developed with gallic acid, and fixed with hyposulphite of soda.

I do not expect to find this method of preparing waxed-paper any better than the turpentine waxed-paper process, but I think it desirable to give it a trial, in conjunction with the other, so as to establish a just comparison.

I have always been a strong advocate of waxed-paper processes for out-of-door work, and I think if sufficient care and patience were bestowed upon them, few photographers would encumber themselves with collodioned plates at this season of the year, when good results are so uncertain.

When we return I shall essay the various preservative processes — from Taupenot to the end of the chapter.

Photographic Glossary.

Oxides of Silver — There are three oxides of silver: the *suboxide*, consisting of two atoms of silver in combination with one atom of oxgen; the *protoxide*, composed of one atom of silver and one atom of oxygen; and the *per*oxide.

Oxyacids — In chemical nomenclature this name is given to those mineral acids into the composition of which oxygen enters, such as nitric acid NO_5, sulphuric acid SO_3, &c., in opposition to the hydracids, or acids into the composition of which hydrogen enters, as hydrochloric acid.

Oxygen — A colourless, inodorous gas, probably the chief constituent of the physical world. It forms one-fifth of the atmosphere and eight-ninths of water, while most of the earths and metals are oxides. It is the chief supporter of combustion and of respiration.

Oxyhydrogen Light — Oxygen and hydrogen gases mixed in the proportions in which they combine to form water burn with an intense heat. The oxyhydrogen flame thrown upon a cone of burnt lime has been proposed for illuminating objects so as to enable photographic pictures of them to be taken at night.

Oxymel — A mixture of acetic acid and honey, much used in pharmacy. It is employed as a preservative agent in photography for excited collodionised plates.

Ozone — Atmospheric air, or dry oxygen, when exposed to the passage of a series of electric sparks, emits a peculiar and somewhat metallic odour. An examination of this odourous air has shown that, in addition to the smell, it assumes several properties not exhibited by pure oxygen. One of its most curious effects is the liberation of iodine from iodide of potassium. It is supposed to be a peculiar modification of oxygen, in which the affinities of this element are enhanced in a remarkable manner.

Palladium — This metal closely resembles platinum in colour and appearance, but is less dense and more oxidisable than that metal. It is slowly attacked by nitric acid, but readily dissolves in *aqua regia*. Protochloride of palladium is recommended by Dr. Draper for darkening collodion negatives.

Paper — Photographic paper is a pure form of cellulose. It is composed of vegetable fibres, as linen, cotton, and flax. As various chemical reactions take place among the materials which form the photographic image, it is necessary that the paper, which serves as a vehicle, should be of the greatest possible purity; hence it becomes a special object of manufacture, the aim of which is to produce a texture as fine and as even as possible, free from spots, and strongly sized, so as to resist the prolonged action of water. It is extremely liable to be contaminated by fragments of iron, brass, and lime, which produce fatal defects in the photographic picture. These foreign bodies

may be removed by immersion in weak hydrochloric acid, and afterwards washing in running water, but the sizing is impaired by this treatment.

Pendulum — A pendulum vibrating seconds is a convenient apparatus for the photographer, in the absence of a clock or watch. The length of such a pendulum is about thirty-nine inches and may be easily extemporised by a plumb line, &c.

Pentasulphide of Potassium — Liver of sulphur. A compound of one equivalent of potassium with five equivalents of sulphur. It is used in photography as a means of converting residues of silver into the sulphuret.

Phosphates — Combinations of phosphoric acid with bases, the most important of which, in photography, is the phosphate of soda.

Phosphate of Soda — There are several phosphates of soda, of which the common tribasic phosphate is of most importance in photography. It consists of six equivalents of soda in combination with two of phosphoric acid, united with water of crystallisation, and crystallises in oblique rhomboid prisms, which are efflorescent. Phosphate of soda is an ingredient in Mr. Maxwell Lyte's toning bath.

Phosphoric Acid — An intensely sour and powerful acid. In its anhydrous state it exhibits as great attraction for water as anhydrous sulphuric acid. When thrown into water it combines with it with explosive violence. Once in a state of hydrate the water cannot be again separated.

Phosphorus — A metalloid which has a great affinity for oxygen; it inflames spontaneously in the air, and must therefore be kept under water. The reducing power of the fumes of phosphorus have been turned to account in photography.

Photography — The art by which pictures are obtained by the action of light on certain sensitive agents, the principal of which are the chloride and iodide of silver.

(To be continued).

New Books.

The Photographic Tourist. Third Edition.

F. J. Cox, 22, Skinner Street, Snow Hill.

This is a useful little manual, and in it will be found a very good account of the collodio-albumen process, introduced by M. Taupenot, that being the dry process most preferred by the author, as applicable both for taking negatives and also for printing transparent stereoscopic positives on glass.

In the section devoted to positive printing upon paper we regret to find the hyposulphite of soda toning bath still recommended, although it must be admitted that the formula given is one of the *least* objectionable. The author may possibly think this remark rather hard, seeing that we formerly advocated a similar toning bath. True; but it was before we knew of a better one. Photography is like the bean-stalk famous in nursery literature, and grows at railroad speed. Those who have once tried the toning bath suggested by Mr. F. Maxwell Lyte will not be likely to abandon it for any other very readily, it being sound in theory and easy in practice: it is, in our opinion, unquestionably the best yet introduced.

For mounting paper proofs we consider that the author has erred in recommending gum-arabic — stiff glue used hot is a much better article; also india-rubber solution has many greater advantages.

Besides several other matters, the book concludes with details of the oxymel process and the method of printing upon opal glass in the camera, including also instructions for producing photographic slides for the magic lantern.

Catalogue of Photographic Apparatus, Processes, &c.

Murray & Heath, 43, Piccadilly.

We have had this before us some little time, but owing to a pressure from abundance of more important matter, have been unable to notice it earlier.

A correspondent in a recent number held up to ridicule pamphlets of this class generally under what we believe to be an erroneous impression — upon the principle that "what is to be had for nothing is worth nothing" — but as the publishers "reserve the right" to charge sixpence for each copy of the present pamphlet, perhaps it may be questionable whether it would come under the above category.

The object of the *bookling* is to promote a taste for photography, and to smooth the way in its pursuit — thus creating a demand for materials and apparatus — of course in the hope that, out of gratitude for help afforded, the recipients may become customers to the parties assisting. This is quite legitimate, and put forth without any false pretence.

Besides the usual descriptive matter relative to apparatus and certificates of excellence from many noted photographers, there are various useful recipes and processes given.

We regret, however, to perceive that one generally so acute as Mr. Heath shows himself to be, should have been misled by the following, which we extract, viz.—

"M. Niépce says 'that pictures printed with a salt of uranium, and developed with nitrate of silver, will resist the energetic action of a boiling solution of cyanide of potassium.' And he adds: 'everything therefore leads to the hope that this new mode of printing positives is the sought-for solution of that important problem — the absolute fixing of photographic pictures.'"

It is quite true that the assertion was made, but if he had simply tried the experiment he would have found it *an assertion*, AND NOTHING MORE.

Foreign Correspondence.

Paris, July 9, 1859.

The scientific world in general, and the photographic world in particular, prefer, I opine, nature to art at the present season. At various *reunions* which I attend in virtue of my office, I am frequently one of a select circle of the three or four who compose the audience. Who can patiently listen to papers on "lactic acid," or the "functions of the spinal marrow," read under a temperature of 88°, with a thunder-storm looming over head? Is not this pursuing knowledge under difficulties? My ardour in the pursuit of science would carry me to the top of Chimborazo, but under the baking heat of an inland city my energies fail. An unusual prevalence of thunder-storms would seem to have some connection with the mortal artillery of Magenta and Solferino. At any rate they are watched and listened to with peculiar interest just now, and a sudden thunder-clap will bring all Paris to its doors and windows, with blank expectation in every face. If your Journal was appropriated to meteorology, I could fill every column with curious facts and bold theories on the unusual phenomena of the present year. But photographic philosophy melts away like ice before a midsummer sun, and your correspondent's office is little more important than "chronicling small beer."

We have not yet done with our "new action of light." You may believe it or not, just as you please. What I communicate is believed here, and I must own myself perplexed, when I see our discoveries questioned, disputed, and denied on your side of the channel. I think it would not be difficult — it certainly would be very satisfactory — to test what M. Niépce claims for his discoveries. The experiments lie within the capacity of almost every tyro in science. M. Niépce thinks that he has observed a new phenomenon connected with the discoveries he claims to have made. He finds that if a small quantity of a solution of starch or of dextrine be submitted to the action of the sun's rays for about a quarter of an hour, it will be entirely converted into glucose or grape sugar. The presence of the sugar can be easily proved by the ordinary tests, or more readily by the sweet taste of the solution. If the result of this experiment be verified the transformation will explain a great many natural phenomena. Every day witnesses the formation of considerable quantities of sugar during the ripening of fruits, and M. Niépce considers he has proved that, by enclosing bunches of grapes at the beginning of autumn in paper bags saturated with tartaric acid, he not only accelerates their ripening, but also greatly increases the quantity of sugar they contain. Tartaric acid, as well as nitrate of uranium, has, he maintains, the property of storing up light in a state of activity and chemical efficiency. But it is no use recommending you to repeat this experiment, for I have heard, on very good authority, that the sun seldom or never shines in England.

Photographers who have gone to the seat of war to exercise their talents remark that the time of exposure in the camera has to be greatly increased, even when working with the same apparatus and chemicals as employed at home. This fact, that actinism diminishes as we travel southwards, was noted many years ago by Dr. Draper, of New York, in removing from that city to Charleston, in South Carolina, a distance of about 650 miles. M. Berchtold, whose improved process of photographic engraving I described in my letter of 24th May (p. 141), has discovered a method of producing these engravings in relief, so that they can be printed at the ordinary printing press, like wood-cuts. By employing a negative as a *cliché* he is enabled to bite the metal sufficiently to produce a design in relief, without injury to the delicacy of the design. The metal he operates upon is zinc. I have just been shown some

photographs in carbon and coloured pigments, which are the most perfect things of the kind I have yet seen. They have all the qualities of proofs obtained with the salts of silver, and by many will be thought superior. The inventor is M. Lafon de Camarsac, who some time ago invented enamelled photographs. He appears to have completely solved the problem of unchangable positives, whether in carbon or coloured pigments. Had he been a little more alert he might have won the De Luynes prize. J. P.

Correspondence.

[We have received the following in consequence of our remarks upon the Annual Report of the Blackheath Society, relative to the introduction of salts of uranium as photographic agents.]

SALTS OF URANIUM, &c.

To the Editor.

Sir,—I was one of the very first experimenters, I believe, in photography, and I fixed photographs with ammonia and salt, which I believe, as far as I could hear, were the first paper photographs of any kind ever fixed at all. I never published my experiments, and other pursuits and residence abroad had entirely diverted my attention from photography. In 1854 I got hold here of, I think, Hunt's *Researches*, and Bingham's *Manual*, and found an immensity had been done which I knew nothing of. I first began again with experiments built on Mr. Ponton's chromotype and on Sir John Herschel's iron process, and succeeded in producing in this way my cuprotype and the ink process with binoxalate or ammonio-oxalate of iron and chromic salts, as well as many results published, and some others *yet unpublished*. During the course of the winter of 1854-5, and the summer and autumn of 1855, I made very many thousands of experiments in the directions indicated, as well as with every one of the metals or their salts which I could by any means or at any price get hold of, and also with a great variety of organic substances. These experiments were in *no* case made at random, without some *definite* idea, or some distinct expectation of exact results wished to be attained, but the whole being guided by my knowledge of chemistry, which has long been a favourite pursuit of mine.

Among the metals on which I experimented much, besides those in new directions with metals already to some extent tried by others, were *tungsten, titanium, molybdenum*, and *vanadium, rhodium,* palladium, uranium* — hitherto altogether untried. Uranium I found to be the most prolific of all in good or interesting results, palladium the next.

A meeting of the British Association being about to be held in Glasgow, I wrote to the Secretary, telling him I had a lot of novelties in photography which I should be happy to communicate. He replied they would be happy to get them; so I went over, taking with me my specimens and notes. I was put down in the lists of sectional meetings for a paper entitled *Photographic Researches*; but, with the exception of some short allusions to my experiments with other metals, iron, chrome, &c. &c., confined myself to, first, uranium and the various developments of it with silver, gold, and palladium, ferridcyanides and ferrocyanides, and the modes of toning the prints so produced; and secondly, to pointing out the rationale and analogy with Sir J. Herschel's ferric processes, and describing some improvements in the latter, by toning with gold, &c., and fixing them with ammonia, &c.; and thirdly, by giving a few short statements as to some of my attempts to improve the old silver processes, by the introduction of the organic or other salts, as advantageous both for negatives and positive prints. I showed at the meeting (besides the few specimens which, finding there was a photographic exhibition connected with the Association, I put into it) a great many more, most of which were afterwards given away or lost, or used up in experimenting farther on them as to toning baths, &c.

I showed also, though *not described* in my paper or *Photographic Notes*, either the scraps I showed you when here, or others *like them*, of the effects produced by newspaper and book *print* on the uranic paper from absorbed actinism, that is to say, they lay on the table; but the time was short, the hour of the section being nearly up, and I merely alluded to them as results owing to absorbed light, allied to those published by Möser, which I intended farther investigating.

My paper was not published in the Reports. I was asked to re-read it at our Photographic Society, in February, 1857, and did so, with some *abridgments*, alterations, and insertions, as you will see by the report in *Photographic Notes* of March, 1857. The editor refused, at first, to mention that the paper had been previously read, as it would derogate from the dignity of his publication to republish anything, and some at least of our Society's Council also objected to the insertion of such a notice, but I afterwards insisted on the acknowledgment of the fact.

Not only have I given these and *every other* photographic discovery which I have made *freely* to the public, but have *given away* and offered to any one who wished them large quantities of oxide and salts of uranium, and prepared paper and everything necessary, as well as offered any farther advice, instruction, or explanations to any one asking for them, either by word or writing.

Previous to the *re*-reading alluded to, I ordered from London 1 lb. of the oxide which was on that occasion, along with nitrate, prepared paper, and development salts, offered to any one who liked to take them; and no one coming forward, several ounces of the oxide were placed in the hands of our honorary secretary, *pro bono publico*.

I send you a copy of my old pamphlet on *Photography in Colours*, far superior, I believe, to any of the *new* patents in the same direction which have lately been published. Had a patent been taken out, I have no doubt it would have paid and been at work long ago; but such is the world we live in—what is to *be had* for nothing is valued as *worth* nothing. Even as it was I should have had it at work, were it not that there was but one chromo-lithographic printer here, and he, though a most excellent chromo-lithographer, so wedded to the old system that I could not get him to take it up, though to be paid for his trouble. However, the whole will be probably patented and brought into use some of these days. One of the patents published in a late London journal shaves part of it very closely. I have no doubt the patent-mongers hate me heartily for discovering and giving freely to the public what they would have coined — or tried to coin — money out of; but they need not, for I doubt very much whether they are generally capable, had they the opportunity of as long a life as Methuselah, of anything more nearly *approaching* discovery than piracy or petty alteration (generally for the worse) is.

I send you the rough slip of a short explanation which ought to go along with "John Brown of New York's" pamphlet, explaining so far the *main* principle of it.

I see, on looking at the paper of Dr. Draper, that it does contain some more details than I gave. Dr. Draper is a man of real ability and an original discoverer, and not one of that crew whom I have some cause to detest. Still you may note, *en passant*, the fact that I had previously *in your Journal* pointed out the application of the chloride and other salts of palladium for toning silver prints, &c., as well as for developing uranium prints; but this is a mere bagatelle, not worth naming alongside that most monstrous and systematic plagiarism to which, in defiance of the published evidence, the Blackheath Council has seen fit to volunteer its certificate of genuine and prior discovery. * * * * Thank you, however, for bringing my claims under its formal and especial notice. I am a lover of peace, and would rather not believe any evil (especially of brother photographers) which I am not *compelled* to believe; so, though they scarcely deserve it, they shall have time and opportunity to amend their false position, which doubtless they will be happy to avail themselves of.

There was one palladium-developed uranic print in the Exhibition, at Suffolk-street, and several more were sent but not exhibited, though their entire novelty *might* have ensured them a place, even though rather late in arrival. The "leather-varnish" of Blanquart Evrard is a copy, *exposed at the time it appeared*, and admitted to be no novelty even by the editor of a contemporary publication.—Yours, &c.

C. J. BURNETT

* There is, however, an allusion to palladium and rhodium in Mr. Hunt's valuable *Researches*, but without its appearing that any results worth mentioning had been obtained from either, or without saying how they were tried — probably alone on paper, in which way they are *much* too slow for any practical use.

PHOTOGRAPHIC TENT.

To the Editor.

Sir,—In your article on the meeting of the South London Photographic Society, in your Journal of the 1st instant, you give us Mr. Leake's method of constructing a tent for out-door photography; which, with all due deference to Mr. Leake, is far from a new invention. A friend of mine has used a tent of exactly the same construction this last year or more.

One thing we find very inconvenient, viz. — there is nothing to fix the bath, bottles, &c. to, having only the small iron supports at the corners.

If Mr. Leake, or yourself, would be kind enough to give us a good method of fixing the movables during the manipulation, I think he would oblige many besides yours, &c. OXONIENSIS.

POSITIVE PRINTS OF VARIOUS HUES.

To the Editor.

Sir,—As a constant reader of your Journal, I met with directions in your number for May 1st (page 114) for obtaining coloured proofs. But as I did not succeed, I imagined that there was some peculiarity in your use of the words "positive paper," "negative paper." Can you kindly, in your next number, insert some explanation of the words "positive" and "negative?" For they evidently do not mean ordinary positive or negative paper, in the *manufacturer's* sense, but that which is *chemically* positive or negative, I *suspect*.—I am, yours, &c.

June, 29, 1859. AMATEUR.

[The directions given are not ours, but those of our *Paris Correspondent*, who reports a rediscovery by M. Nièpce de St. Victor of a process long ago published by our friend Mr. Burnett. We have no doubt that the "positive" paper there mentioned simply means such as is used for printing upon as regards the fabric, which is *stronger* than the kind used for negatives.—Ed.]

CONSTITUTION OF THE PHOTOGRAPHIC IMAGE.

To the Editor.

Sir,—The experiments of MM. Davanne and Girard tend to confirm what has been surmised by many photographers, that the altered state of the exposed film is its reduction to the metallic state.

There is, however, one point they have left untouched—the over-exposed plate. Allowing that lights and shadows are regulated by the more or less mineralisation, how is it, that in an over-exposed plate (the sky for instance) this reduced metal refuses the action of a developer? One would imagine that when the iodide is totally decomposed the liberated silver ought to be in the best state for combining with other molecules of silver, but evidently the metal brought into existence by exposure to light undergoes a reaction.—I am, yours, &c.

Islington, June 27, 1859. THOS. A. BARBER.

[We do not at all agree with our correspondent relative to the opinion expressed by MM. Davanne and Girard, regarding the *metallic* constitution of the photographic image. We neither consider the surmises correct nor the experiments of those gentlemen corroborative thereof. We allude to this matter in our Leader. The very point now adduced by our correspondent militates very strongly *against* the theory suggested, especially when taken in connexion with other known facts.—Ed.]

DIFFICULTIES IN FOTHERGILL'S PROCESS.

To the Editor.

Sir,—Perceiving, every time I read your Journal, your kindness in answering the letters of your various correspondents, and especially your anxiety to put those right who are wrong, I am desirous of profiting from your advice, respecting a series of failures I have had this year with the Fothergill process. I may just say that, last season, I tried this process and was very successful with it, using an old bath; this season I made a new bath, and bought a first-rate set of new apparatus, thinking that, as I had managed so well last year with the small sizes, I might produce larger pictures this year.

My bath is made of fused nitrate of silver, forty grains to the ounce. I have tried all sorts of collodion—Keene's, Horne and Thornthwaite's, Ponting's, &c., &c.; and, as I am an operator of two years' standing, and as some of my friends have had plates sensitised in my bath, which have turned out good pictures, there can be nothing wrong there; but it is in the developing, I think, where my failures are made, and for the last three months I have tried unsuccessfully to ascertain whence it has originated.

After exposing the usual time I put my plates in a dish of distilled water, and afterwards develop in the usual way with pyrogallic acid and a few drops of silver. Now, I find that, after the developer has remained on the plate a short time, small red spots appear, and these gradually form into black marks (thus + † × †), and completely spoil the picture. On a plate 12 × 10 I have seen some hundreds of these marks.

Now, sir, I have had some of our best photographers to look at them, and they cannot tell me anything about them. I consulted —— & ——, and they could not tell me either; what makes me think it is in the developer is, that some plates I have prepared and given to a friend have turned out good pictures, while some that the same party has prepared himself from his own bath, have in *my* hands turned out like my own, and in his plates, from the same bath and the same process, have been all right. —— & —— suggested that the developer should be carefully filtered—an operation which I performed but with no better results.—I am, yours, &c.

A MARTYR TO THE "FOTHERGILL PROCESS."

[Your failure is, doubtless, due to the development—not the developer. The marks you mention indicate the presence of *foreign matter on the surface,* which form centres of chemical action.

The dish of distilled water—do you wipe it free from dust before putting in the water, and are you certain that the distilled water itself has no floating particles? Again, are your measures clean with which you pour on your developer?

Lastly: The nitrate of silver added to the developer—is it some of the bath, or fresh solution?

However, proceed as follows:—Take a piece of *old, well-washed flannel,* and tie it over the mouth of the tap of your cistern. Attach a pneumatic holder to the back of your plate; hold it under the tap and let the water fall on the centre of the plate through the flannel, which not only breaks the force of the stream, but arrests any little floating particles. Incline the plate in every direction so as to wet the whole surface; it should not be soaked, but wetted as quickly as possible, and with but little water. Drain for a few seconds, then flood over it about half an ounce of *distilled water* from a clean measure; pour it off and drain slightly. Previously to wetting the plate, put into a clean measure about ten minims of *fresh* (that is not bath) nitrate of silver solution, and in *another* the quantity requisite of pyrogallic developing solution. While draining from the distilled water, mix the above together, and immediately pour the same over the plate. When developed, wash under the tap as before. We think that if you attend to the above you will have no more trouble with the spots you name.—Ed.]

PRINTING ON OPAL GLASS.

To the Editor.

Sir,—In the course of my experiments upon opal glass, I found that by increasing the gelatine solution to twenty grains, and adding two drops of ammonia to each ounce, I got a beautiful delicate pink tint. I have repeated the same several times with exactly the same results, and therefore would recommend this alteration in my process to those who are operating in this direction.—Yours, &c.

Liverpool, 6th July, 1859. J. A. FORREST.

ANSWERS TO CORRESPONDENTS.

Querist.—Alcohol 4 oz., ether 6 oz., pyroxyline 60 grains.

W. W. (Truro).—We cannot recommend makers; each has doubtless his respective merits, which you must ascertain for yourself.

Peter Pindar.—We have seen the French photographs you mention in the shop windows in the Strand, London.

Anakin.—Your article is not declined, it has merely stood over for want of room: it will improve by keeping.

Linch-pin.—You will find the tables you require in *Lay's Photographic Almanac,* page 65.

H. Nicol (Berwick).—You will find a very good note on collodion in No. 90, page 74, of this Journal.

A Subscriber.—The number referred to is out of print, and cannot be supplied at present. Your suggestions shall have attention.

A Beginner.—See "Letters to a Young Photographer," No. 4, and the article in our "Photographic Glossary."

Ben Trovato.—Messrs. Marion's photographic manufactory is at Courbevoie, on the Seine.

Caroline inquires if there is really such a person as Eusebius. We will send his portrait in exchange for her own if she agree to this arrangement.

P. C.—Sterne—A. M.—In every number now we have to repeat that we cannot write privately to any but personal friends. Through the Journal we are always ready to afford our best services.

Tyro.—The strength of cyanide of potassium is very uncertain; better make the solution too weak than too strong. You must ascertain the strength of your sample by experiment.

William.—Marine glue is said to be composed of caoutchouc one pound, dissolved in four gallons of crude naphtha. When dissolved, add two parts by weight of shell-lac to one part of the solution.

Oxon.—You do not require expensive apparatus to study the elements of chemistry with. Ten shillings judiciously expended will procure all you require.

G. Brand.—The book is very scarce; there is no copy in the British Museum Library. A photographic copy of the title page would be a curiosity and highly prized by the bibliomaniacs.

S. S. (Halifax).—The engraving is exposed to the vapour of iodine, and then placed upon a polished copper plate; under pressure, the design is transferred to the copper, and inked; then the plate is etched by nitric acid. The theory of this process bears some analogy to the Anastatic.

Sambo.—In Maxwell Lyte's toning bath you must tone to a purple, approaching even a bluish, to acquire black tones after submission to the hyposulphite of soda. The slightly red hue, when wet, disappears on drying.

J. W.—We invariably employ for our own use in this way our own simple honey process, which you will find detailed in several of our late numbers, in reply to other inquirers. It does not occupy more time than ordinary wet collodion in preparing or developing, except about *one minute* additional to cover the plate with syrup.

Liquid Glue: W. F. H.—The cement sold under this name is simply a solution of shell-lac in methylated spirits of wine. A very excellent liquid cement for uniting pieces of bone, horn, pearl, or shell is made by dissolving one ounce of gelatine in one ounce of strong vinegar (Beaufoy's), adding two drachms of alcohol, and a pinch of powdered alum. The bottle in which the ingredients are contained must be placed in a vessel of hot water until they are dissolved, stirring occasionally.

THE PHOTOGRAPHIC JOURNAL.

No. 99, Vol. VI.—AUGUST 1, 1859.

In our last issue an advertisement was inserted by the "authorities" of a Photographic Society in the north, announcing their intention of awarding prizes, consisting of silver and bronze medals, and also one of money, intended of course for the encouragement of photographic excellence.

This is a course of proceeding which we much regret to see adopted by a Society professing to hold an important position, and numbering amongst its members very many skilled operators. Prizes may be all very well for the purpose of holding out an inducement to mere beginners to attend to the niceties of manipulation requisite to produce results fit for competition—though even in this case considerable difference of opinion exists as to the soundness of the policy; but when such are offered to those who are proficients, it appears to us a measure puerile in the extreme.

Setting aside however the question, whether the presentation of prizes at all is conducive to progress, there are other and very grave objections to be noticed relative to the announcement to which we refer, and some of them we will discuss—not by way of tendering any intrusive advice to those who would probably regard it as an impertinence—but as the announcement has been made by public advertisement, and is one ~~which we regard as affecting~~ photographic interests, we presume that we shall be quite in order in expressing an opinion, and pointing out the way in which we fear that evil, instead of good, will be likely to arise from the acts deprecated.

In the first place, we are credibly informed that the award of prizes by the same Society, after holding its last exhibition, gave much offence and dissatisfaction, and produced an amount of "envy, hatred, and malice, and all uncharitableness," painful to contemplate. We do not for a moment mean to assert that the recipients were not worthy, or that any undue favour was shown to them. On this point we express no opinion. But we do assert that the method adopted of selecting the successful candidates was altogether wrong in principle; it having been by a majority of votes obtained from the general body of members of the Society. Such a method can never be satisfactory, liable as it is to every variety of caprice; and we are convinced that under such a system, be the prizeholder whomsoever he may, he will be sure to come in for a large amount of ill-feeling.

One of the principal objects of the managing body of any Photographic Society should be emphatically the *promotion of good feeling and kindliness* between those who are engaged in a common pursuit; it is in our opinion of the highest importance to the well-being of any Society. Can a measure which tends directly to destroy this desirable object be regarded with other than suspicion?

In the official announcement of the intended prizes nothing whatever is said as to the method of awarding them; and the vague manner in which the classes are defined is not calculated to insure any amount of effort whatever on the part of exhibitors. Any one having a picture tolerably good may exhibit it upon the *chance* of getting one.

A silver medal is offered for the best photographic *portrait* or *group*, and a second similar medal for the best photograph of *any other subject* than the above. This looks as if a portrait were estimated of equal value with a group, other things being equal: nothing whatever is said about the sizes, while all other subjects are quietly classed together—such as landscapes, copies of paintings, stereographs, statuary, still life, clouds; but how the *relative* merits of such an incongruous collection are to be ascertained not even a hint is given.

The perplexity is still further increased, as regards the Maconochie Wellwood prize of ten pounds in money, to be competed for by the professional members of the Society only, in consequence of groups of figures being also included as entitled to competition—the only kind of photograph excluded being *single portraits*.

What good can the managers of the Society hope to attain by so ill-devised a scheme? Is it to be expected that exhibitors will put out their strength (supposing them to care for a prize at all) without first knowing what are the rules by which their productions are to be judged, and *who* are to be the administrators thereof? We are curious to know how composition pictures from several negatives, such as our friends Rejlander, Robinson, &c., produce, would be dealt with—not that there is much chance of one at least of these gentlemen exhibiting.

But if we regard the prize scheme for pictures ill-designed, what shall we say to the offer of bronze medals, with various clogs appended by way of conditions, for *approved original communications*, to be primarily submitted to the Society (we presume the Council only) and to be *subsequently* read at the ordinary meetings, and published as part of the transactions? What a truly attractive proposition for authors! How fresh and original the papers will appear after having been *primarily submitted* to some score of gentlemen! What a dignified position for those who devise "inventions, discoveries, and improvements in the optical, chemical, and mechanical departments of the photographic art!" Do the promoters suppose that *inventions* and *discoveries* can be "made to order" like a coat or a pair of boots? Are those who offer the prizes to be the judges? Their competence for the office would seem to be dimly shadowed forth by the delicate insinuation conveyed in the fact, that the producer of a fine photograph (if even a portrait only) is to be rewarded by a medal of silver, while he who devises the means of its production must be content with bronze—it should have been brass!

This proposition is altogether a gross mistake, and looks very much as if papers to be read at the meetings are scarcely to be obtained by ordinary means; if so, we are morally certain that the steps now taken are not likely to improve the aspect of affairs. We doubt whether one single follower of the scientific part of photography would not rather be deterred from allowing any of his productions to be read before a Society which acts as if offering lollipops to a schoolboy.

It has often been remarked that there is more in the *manner* than in the *matter* of some actions; and truly some things that are inoffensive in themselves can be made highly obnoxious by their mode of presentation. Now, if prizes are to be given for papers at all, nothing approaching to *competition* should be admitted in the matter. Can any of our readers point out a prize poem or prize essay that is worth the paper on which it is written? We believe that the only method by which there would be any chance of succeeding by the award of medals, in

the object of encouraging the presentation of papers to be read at the meetings of the Society, would be to leave authors untrammeled by any conditions whatever, and to announce that in case any papers, *meriting such distinction*, should be presented and read, medals would be awarded subsequently in acknowledgment.

Many of our readers are doubtless aware that the meeting of the British Association for the Advancement of Science for the present year is appointed to be held in Aberdeen, under the presidency of H.R.H. the Prince Consort. It has been determined by the local committee to hold an exhibition of photographs in connexion with the meeting; and as the Royal President is known to be an ardent admirer of art in general, and leader of photographic art in particular, we may doubtless calculate upon a goodly display. To promote so desirable an object, and for the convenience of our readers, we extract the following regulations from the circular that has been issued :—

All descriptions of photographs will be admitted, except coloured ones. Touched positives, or prints from touched negatives, must be described accordingly. It is strongly recommended that they be framed and glazed, with a margin of mounting board not more than two and a-half inches all round, and that those smaller than 9 × 7 inches be arranged four in one frame. They should be marked on the back with the names of the subject, the process (collodion, waxed-paper, &c.), the artist, and the owner.

A list of the photographs should be enclosed in the case, and a duplicate list forwarded by post to the Honorary Secretary, 107, King Street, Aberdeen.

Facilities will also be given to the makers of photographic apparatus, &c., for the exhibition of such of their productions as may be considered of peculiar interest from excellence of construction or novelty of invention.

Contributions are requested to be sent in not later than the 1st of September, carriage pre-paid, addressed to "The Photographic Exhibition, Music Hall Buildings, Aberdeen." At the close of the Exhibition, they will be carefully re-packed, and returned, free, to the owners.

JOHN F. WHITE, Local Secretary.

107, *King Street, Aberdeen,*
7th July, 1859.

With regard to the above we have one or two suggestions to offer to the managers, which we think, if adopted, will tend materially to enhance the value of their collection.

The first is to avail themselves of a very successful and economical plan for exhibiting *unglazed* specimens, simply mounted upon card-board, employed at the Leeds meeting, and which was subsequently described in our report of that collection, at the latter part of last year. The cost of transport to so great a distance as to Aberdeen, together with the risk of breakage of glass and frames, would deter many from sending their works, and at any rate, reduce the number likely to be sent; while the expense of forwarding unmounted specimens is comparatively trifling, and the plan followed by the Leeds committee entails no waste of glass, and so little of wood and other material, that the entire cost of the whole would be more than covered by the saving in the way of carriage and packing cases.

The second is to *classify* the subjects in some definite manner, especially to separate portraits, landscapes, and reproductions from one another, the value of each class being dependent upon totally different points. It is a great mistake to hang these productions jumbled altogether, as is too commonly done.

In a letter which appeared in the last number of the *Journal of the Photographic Society*, from the pen of Mr. N. Ennel, a gentleman who has displayed considerable ingenuity in devising several useful mechanical contrivances connected with photographic apparatus, we find him asserting that the use of a swinging back to a camera, or any equivalent thereto, is "wrong in principle," and in corroboration cites "a simple experiment with the common burning glass held between the sun and a cardboard. If the common axis of the sun and lens do not intersect the plane of the cardboard *perpendicularly*, the image of the sun is thereon represented *elliptically*." He then goes on, "substituting landscape, &c., and focussing screen for sun and cardboard, we arrive at the same result: we may, indeed, get most points in good focus, *i.e.*, *distinct*, but *every one* point will be distorted."

As we cannot assent to the premises, of course it is not at all surprising that we do not agree with the conclusions; but setting aside for the moment the question whether the use of a swinging back camera is wrong or not in principle, we would ask for a nicer definition of what he means to be understood by asserting that *every point is distorted?* We are almost tempted to fancy, from the experiment he has quoted, that he is not quite familiar with the conditions under which advocates of the "swinging back" recommend its use. The sun subtends but a very small angle of vision, and such as it is the two opposed limbs are not at any appreciable difference of distance from the spectator, consequently in substituting the equivalents in a landscape subject, we should define it as a small window immediately in front of and not very close to the operator. Certainly this is not a subject requiring the aid of a swinging back, which like all other things can be misapplied. Mr. Ennel must select some happier illustration to uphold his argument; let him try to focus one side of a street or lane disposed very obliquely towards him and he may alter his opinion.

With regard to the charge of *distortion*, Mr. Ennel must mean something different to what is usually understood, the latter being a quality due to the *lens* and not to the swinging back. By inclining the plane receiving the image from a lens, the *scales* upon which the objects on opposite sides of the axis are depicted differ somewhat it is true. If this be what he intends by *distortion*, the error is one of degree only, for the same thing occurs to a less extent, even when the axis of the lens is perpendicular to the plane of delineation, in which case objects situated at the margin are depicted upon a slightly larger scale than those in the centre. The only remedy for this evil, that can be regarded as perfect, is that of delineating upon a concave surface, as it always must arise when focussing upon a plane surface however disposed, from the impossibility of the various parts being situated at the same distance from the optical centre; in other words, the length of focus is continually increasing in a series of circles, of which the perpendicular axis of the lens is the centre.

Whilst a plane surface of delineation is regarded as imperative no radical cure can be applied, but a palliative may be employed; and this is best found in constructing such a lens as will throw the optical centre further from the plate than the lens itself, the segment of a sphere of *longer* radius being less removed from a plane surface than a segment of corresponding dimensions from a smaller sphere.

We feel no hesitation in alluding to Mr. Ennel's remarks, being assured that he is only, like ourself, animated by a desire to advocate that which he regards as sound in principle. We shall be most happy to discuss the matter with him.

In another communication to be found in the last number of the *Journal of the Photographic Society*, under the signature "Meniscus," dated from Dublin, an inquiry is made relative to the probable permanence of proofs toned by a somewhat cumbersome method, devised by M. Jobard, and described in a recent number of the *Bulletin de la Societé Française de Photographie*, in which perfect stability is claimed for them by the author. Lest some of our readers should be induced to put much faith in the recommendations set forth, we would draw their attention to the fact, that sel d'or is used for the toning, a salt containing sulphur, producing its action by converting the silver of the impression into a sulphide of that metal, and depositing gold in a metallic state. The employment of sel d'or as a toning agent was an immense advance upon the use of old hyposulphite of soda; but this, in its turn, has been superseded by the alkaline chloride of gold compounds. We have no

hesitation in pronouncing Mr. Maxwell Lyte's method far better than M. Jobard's; and it is probable that Mr. Burnett's method, published in our last, may be better than either of the others.

WHILE on the subject of Mr. Burnett's labours, we may quote, as interesting, the following remark, made in a letter we received some time back from this gentleman, the letter being otherwise only upon private matters:—

I may, however, tell you that I tried some experiments last autumn and winter on paper prepared with mixed solutions of *gum* (and sugar) and nitrate of silver, which would seem to indicate that it is also, just like the nitrate of iron, or of uranium, or bichromate of potash, capable, along with the gum and allied substances *without the presence of iodides or chlorides*, of giving an insoluble and developable picture, and this is probably the explanation of Mr. Young's experiments.

ON IODIDE OF MERCURY IN THE COLLODION FILM.

By T. F. HARDWICH.

A NEW mode of removing excess of free iodine from photographic collodion has lately been described, in which metallic mercury is used. On shaking the bottle rather briskly the globules of mercury are broken up, and diffusing themselves throughout the liquid, rapidly effect the decolourisation.

On reading the description of this process it appeared sufficiently simple; but whether it could be considered safe was doubtful, inasmuch as it has long been known that salts of mercury have a peculiar action in photography. In the earlier editions of Professor Hunt's work, it is stated that the precipitation of calomel in conjunction with chloride of silver interferes with the blackening of the latter compound by light; and those who have employed corrosive sublimate as an application to photographs, either on glass or paper, have noticed phenomena which appear to indicate affinities between salts of mercury and silver. If, therefore, free iodine in collodion becomes neutralised by combining with mercury, how far will the resulting compound affect the action of light upon the sensitised film? The following experiments were made systematically with a view of determining this point:—

A solution of nitrate of silver was placed in two test tubes, to one of which a relatively small quantity of a nitrate of mercury was added. Solution of iodide of potassium, dropped into each, produced in the one case a precipitate having the characteristic primrose yellow of iodide of silver, but in the other a deposit of a dirty grey colour. In the next experiment a portion of the ordinary iodising solution, containing simply iodide of potassium in alcohol, was shaken up with the green iodide of mercury until it would dissolve no more. The quantity of mercurial salt retained in solution was small; but on preparing a plate with this collodion, and developing with pyrogallic acid, only the high lights of the picture could be obtained after a long exposure.

Next a sample of simply iodised collodion, which had become as dark as port wine by keeping, was agitated with mercury until a very small amount of colour remained. On dipping in the bath, the film appeared to form as usual, but no latent picture capable of development by the ordinary reagents could be produced in the camera.

At this period of the investigation the experiments were discontinued, in order to reflect for an instant on the cause of the discrepancy. A process, described as successful in the hands of others, now fails in the most complete manner! What could be the reason of this? Perhaps the collodions operated on were different, or the developers were not the same? Seeing, therefore, that *simply iodised* collodion and pyrogallic acid had been employed in the former case, *bromo-iodised* collodion was now taken, with sulphate of iron as a reducing agent. A bottle of bromo-iodised collodion red in colour was divided into two parts, and one part having been nearly decolourised by the mercury as before, the two were then carefully compared by placing them upon the same glass. This experiment, repeated two or three times, made it quite certain that no difference existed between the portion decolourised and the other in which the iodine was allowed to remain. The use of the mercury had not diminished the sensitiveness, as it undoubtedly did in the experiment which preceded it. Either the sulphate of iron or the bromide must therefore have altered the conditions; and a very few additional trials served to show beyond a doubt that *the employment of bromide* was the sole cause of the peculiarity.

There is always a satisfaction in successful photographic experiments, but never more so than when a discrepancy between two different observers is cleared up. At a meeting of the Photographic Society, now some years since, the objection of one member to the employment of bromide, that it made the negative weak in the sky, was met by the assertion of another, that in his experience bromides had rendered the sky more intense. These observations, although apparently contradicting each other, were nevertheless both correct; for it is now known that, in presence of some kinds of organic matter, bromide may add to the opacity of the reduced silver, although in pure collodion its action is the reverse. So, again, in the proposed new method we are now discussing: metallic mercury is recommended as a good decolouriser, and yet the first trial seems to show that it nearly destroys the sensitiveness. These contradictory statements are thus reconciled:—The proper effect of the mercurial salt is to lessen sensitiveness; but if bromide be present, this retarding effect is not so perceptible.

The writer concludes his paper by mentioning a fact in reference to this matter which he believes will be found both interesting and instructive. In commencing his experiments he had used a small bath specially for them; but finding that the employment of the mercury in the case of the bromo-iodised collodion was harmless, he conjectured that no injury would result if the plates were dipped in the ordinary portrait nitrate bath. The result, however, of this incautious proceeding was, that when immediately afterwards he attempted to take a portrait in the same bath, with a sensitive newly iodised collodion containing no bromide, it was found impossible to obtain a perfect picture. The bath, in fact, had been thrown quite out of order, although the quantity of mercury which had been introduced into it must have been microscopically small. Without any obvious fogging, the image was imperfect in all parts excepting the brightest lights.

Having repeated the experiment many times, and become satisfied that the bath was really disordered and in a useless state for working with an ordinary iodised collodion, it remained to offer some explanation. The contents of the bath measured eighteen fluid ounces, and not more than two stereoscopic plates had been coated with the decolourised collodion. Was it, therefore, possible that a minute globule of mercury had adhered to the neck of the bottle and been washed into the liquid? At all events, it became desirable to try the action of metallic mercury upon a new portion of bath; and therefore a small quantity was shaken up with a globule of mercury, of the size of a pin's head, and plates were dipped. The result was quite confirmatory, and showed, as before, that simply iodised collodion was partially insensitive in such a bath, but that bromo-iodised collodion slowly yielded a picture. These facts may or may not bear upon the employment of bromide as an accelerator in the daguerreotype process, where mercury is used to develop. In pure collodion bromide retards the action rather than the contrary; but it might, nevertheless, be truly spoken of as an accelerating agent, in the collodion process, if traces of a mercurial salt were invariably present in the film.

Practical photographers will extract a hint from the above paper. —When they employ bichloride of mercury as an intensifier in copying maps, or other similar methods, they ought to be very careful that the plates are washed quite clean, and that none of the mercurial salt finds its way into the bath.

SILVER PRINTING PROCESSES.

Including Salting, Sensitising, Toning, Fixing, and Testing Baths.

By C. J. BURNETT.

(Continued from page 162.)

Palladium Toning Baths.

IN my papers of last year, in this Journal, I pointed out (thus was the first to point out) that the salts of palladium, especially the chloride and nitrate, might be enlisted in the service of the photographer, for the formation of toning baths, and also as ferric and uranic developers, the solubility of the chloride of palladium being an important difference from and advantage over that of platinum which is insoluble in water, and rendering it unnecessary here (as it was there) to resort to the salts of other acids in order to avoid a bichloride, though the nitrate is easily prepared, and it or other soluble salt of either oxide answers well.

Alkaline palladium baths also answer well. In my palladiotype development processes (as in the specimens sent to the last Suffolk Street Exhibition) the colour was generally brown, but when used as a toner the tint varies considerably.

As to the questions of pictorial value and expense, the atomic weight is only about half that of platinum, or one-quarter that of gold, but the difference of specific gravity or volumetric value would

compensate for the difference from platinum. As to expense per ounce of the palladium, the first I bought several years ago was so moderate in price as to be very much in favour of my processes with it. Last winter, however, on making inquiries as to price, I was much disappointed to find that it could not even be purchased for the price of gold, but cost about half as much again per ounce. The cause of this rise was at first very obscure, but after many inquiries I obtained this answer, that it had come into extensive demand for alloying steel, a very minute addition of it to the latter giving great hardness, and removing its liability to corrosion by vegetable acids.

A possible objection to palladium toning may be, that it is said to be more easily acted on by sulphur than are gold and platinum.

So much *pro* and *con* for palladium as a toner; further experience, as with platinum, must decide its value relatively to that of its rival metals.

Iridium and rhodium have some points of promise about them, particularly their great non-liability to tarnishing, or injury by oxygen or other substances, or even strong acids, and deserve further trial in various ways.*

I must also recommend for alkaline baths as substitutes for the terchloride of gold or bichloride of platinum, the double salts formed by their combination with chloride of sodium — salts exceedingly readily prepared, and from their nondeliquescence, far more readily kept and weighed than the simple salts of platinum or gold. They have also the additional advantage of being less liable to precipitate, by alkalies in the bath, the chloride of sodium appearing to have some sort of affinity for the aurate (or platinate?) of soda, and contributing to keep it in solution— so much so, that I am even inclined to recommend the addition of an excess of chloride of sodium to the bath with this view, and still more important should be this addition of common salt to a bath made with the pure terchloride. The chloro-platinite of sodium, as well as the chloro-platinate, should be tried. The corresponding platinum and gold double salts containing bromine, may also be employed (and those of iodine and fluorine possibly merit a trial)—and even in the case of palladium the double salts may possibly have some advantage.

Chloro-palladite of sodium—a beautiful yellow double salt— is a capital toner as well as developer. Chloro-palladiate may also be used but is not so good.

To conclude our remarks on the toning-baths. With the alkaline gold baths and the alkaline platinum-baths which we have recommended,† the photographer has at his command almost any variety of tone which may be wished, according to the colour of the print and the extent to which the replacement is pushed. It must be noted, however, that the delaying of the toning till after hypo'-fixation, which is, in the case of gold-toning, a convenience, as enabling us to know better what we are about, is here, with platinum (and with palladium also ?), no mere matter of convenience, hyposulphite (at least when a mixture with alkalies)‡ being a powerful solvent for the deposited platinum or platino-organic compound. By attending to this precaution, photographers will find my alkaline platinum-bath just as manageable and convenient as my alkaline gold-bath; and while the salts of the lower oxide, &c., have additional recommendations, he need still never be at a loss where common bichloride of platinum, washing soda, and it may be, a little tartaric acid or tartrate of soda are procurable. Good enough proportions are:— Distilled water ten ounces, bichloride of platinum ten to fifteen grains, carbonate of soda one hundred grains or upwards, tartrate of soda (replaceable by a smaller quantity of its acid) fifty to one hundred grains. Nothing can well be simpler than such a bath, either in use or in manufacture. However, we must wait, I suppose, here, as in the case of the parallel gold-bath, till it comes authoritatively recommended from a sufficient geographical distance. My own opinion is that the alkaline gold-bath is decidedly entitled to preference on albumenised paper, but that in the plain papers, nitrate, ammonio nitrate, or other, the alkaline platinum bath is quite as valuable any how, it supplies us (probably at no greater expense, to keep within the mark) with a variety of warm and highly pleasing tones which gold does not give; and as a protection against atmospheric injury, it has even probably some advantage, from the greater extent to which the replacement can be pushed without making the tone too cold or bleak.

In connection with the platinum-bath (and palladium-bath ?) it should be observed, that if we are going to fix with hyposulphite the toning must be delayed till after the hypo'-fixing, on account of the great readiness with which the platinum deposit is dissolved by the hypo'-bath. If, when the prints are dried after toning, the tone does not satisfy us, we have only to immerse them again, either in the same bath or in a *weak* alkaline *gold* bath, till the tint wished is obtained, taking care, however, that they are thoroughly and *equally* wet with *water* before immersion in the toning-bath.

(To be continued).

* The metal, however, is not liable to tarnish by sulphur in the air as silver is, and I should not be much afraid of the toning from this source, and if I recollect rightly, my experiments with sulphuretted hydrogen were in its favour.

I have got not altogether unpromising results with the various toning metals, both by introducing them into the salting solutions in place of a portion of the chloride of sodium, &c., used in salting, and also, in the cases of platinum and palladium, into the sensitising baths, the nitrates being in this latter case the salts used. One plan was to immerse the picture after printing for some time in a bath of carbonate of potash or soda, to promote the action of the reduced silver, or the gold, or other metal's salt associated with it in the paper, as this does not seem to go far enough during the printing. I am informed, however, that in the case of gold chloride, a plan so far the same, but with a sulphureting toning bath, was long ago published by some other experimenter. This system seems also to merit a trial in development printing, particularly with iron developers.

† A phosphate of platinum (or borate ?) precisely analogous to Mr. Maxwell Lyte's gold bath may be made in the same way, or a still purer and more certain one, by precipitating bichloride of platinum with phosphate of *potash* (preserving the precipitate for after reduction) or a bath like Legray's, with chloride of lime, might be made? for those who prefer the other modes of carrying out the principle.

‡ By washing out the alkali from the toned prints, we may perhaps tone *before* fixing with hypo'; and when fixing with ammonia, as in the uranic silver prints, there is difficulty in either way.

ERRATA.—In paper on "Toning-Baths," July 1st, page 162, note 2, line 7, for "potash" read "*sulphate of potash.*"

In last line of paper omit the word "*palladium.*"

In sixth line from the end of the paper omit the word "*or.*"

MODIFICATION OF THE WAXED PAPER PROCESS.

By * * * * * * * M.D.

By the guidance of your valuable Journal it seems probable that the "waxed-paper process" will, during the summer months at least, obtain further attention; let me therefore hope that your readers will kindly deem no apology necessary for the intrusion of the following communication:—

Last summer, for a short period, I used, with a certain amount of success, a formula, **No. 1**, which is given with others containing wax, paraffin oil, and benzole, iodised by iodine; the paper, after soaking and drying, being further iodised by formula **No. 2**; dried, sensitised by **No. 3** (Sisson's formula), and developed by pyrogallic or by gallic acid solutions, after one and two minutes' exposure in sunlight.

Lately my endeavour has been to simplify part of the process. Enclosed are some rude results, which I leave to your superior judgment for any remark, should you deem them worth notice; they seem to offer some promise in more able hands. The chief object is to try and save time and trouble in the preparation of the paper and in development, so that those provided with the necessary means might, on the field, readily note their success. It is needless to trouble you with a statement of the numerous experiments I have gone through. Faulty as you will probably find the method, nevertheless excuse my stating it in detail at the risk of being tedious. Manipulation, as you well know, in chemistry is often one of the terms for success.

The paraffin oil is of the ordinary kind for illumination, purchased last year in town: I was then told we might shortly expect a purer kind. Belmontine may perhaps prove superior; I am just on the point of trying it.

Put two ounces of paraffin oil into a phial; add ten grains of crushed iodide of ammonium and four grains of iodine; shake well; let repose for twelve hours. The paraffin, from a fine sherry colour, becomes quite dark. Filter sufficient into a dish and immerse the papers, avoiding air-bubbles (I have used Turner's, Marion's, and Canson's thin post); turn after ten minutes; remove by a corner with a piece of whalebone; hold the paper over the dish, and draw a glass rod or triangle twice or thrice across the front and back; pin up to dry in a warm room, with yellow light or in the dark; if required before they can dry by this plan, place them on blotting-paper and wipe the back with a little clean cotton wool.

Place a clean ground glass level, rub a bit of bees' wax along its edges; filter on to the ground surface some of the sensitising solution **No. 6**, which always protect from daylight; gently float the face of the prepared paper for two minutes; turn, and float the back for one minute; lift by a bit of whalebone and pass a glass rod over the surface. Now plunge into a dish of filtered rain or distilled water; allow it to remain while you filter a few more drops of the silver solution on to the ground glass; place another piece of paper to sensitise; then remove the former from the water, stroking the surfaces with a glass rod; dry on clean blotting-paper and put away in a dark box between some clean leaves of bibulous paper.

Expose, according to light and object, one-half to two minutes.

The development may be effected by what may be called for convenience the quick and slow methods. For the former, place a piece of glass level, pour on it clean or distilled water, and place the paper face downwards for half a minute; turn, and float the back for the same period or longer; in the mean time pour out some of the pyrogallic solution, **No. 7**, to which one-third distilled water may or may not be added; now pour off the water from the glass, holding the paper on it by means of a piece of whalebone; replace the glass level; drop about four drops of a thirty-grain solution of nitrate of silver into the pyrogallic solution, *and at one sweep flush the surface*, allow it to remain till the development begins; then treat it as in the collodion process, as regards pouring fresh solution off and on, &c. Finish by flushing with water, soaking a short time, and clearing by hyposulphite of soda — strength about one ounce to eight ounces of water.

For the latter or slow plan: equal parts of a saturated solution of gallic acid and distilled water, with six drachms of Beaufoy's acetic acid, to four ounces and a few drops of the thirty-grain solution of nitrate of silver. This develops very slowly.

You will find many faults in the specimens sent, and doubtless will be able to suggest a remedy. *A curious* appearance presents itself on placing some (those named on back) in water with back upwards, say in a gutta percha dish; they then look like positives, indeed like dingy daguerreotyes by reflected light. You will notice this particularly with the wall. Another plan, somewhat more troublesome, is to soak the paraffin papers, when dry, in the albumen solution, **No. 5**, for a quarter of an hour: dry in the dark, and keep in a book or case. I am not able to say how long the paraffin papers will keep good when sensitised; but with formulæ **Nos. 1, 2, & 3**, last summer, they were good for a month if developed by gallic acid, and for a week if by the pyrogallic solution. I have just tried some a year old as regards the iodising, and they gave pretty fair pictures.

The foregoing plan is sent imperfect as it is, even at the risk of my being placed on the list with those who throw off their hasty ideas for others to set in order, and then claim the priority of invention. Very possibly others may have tried paraffin, though I have not seen it named. The simple reasons assigned for its use, without reference to its chemical qualities, are the transparency it gives to paper, the readiness with which the solutions flow to its surface, and its reasonable cost. If we could find some iodide soluble in it, I have reason to think, from my experiments, that the papers may be prepared very readily and very sensitive. The iodide of ammonium is not very soluble in it. The smell may be against its becoming fashionable, even if useful.

If you will kindly state your objections, or indeed any hints, they will be received with every acknowledgement by a subscriber and well-wisher to your Journal.

FORMULÆ.

No. 1.

Bees' wax	1 drachm.
Paraffin oil	1 ounce.
Benzole	2 ounces.
Iodine	15 grains.

No. 2.

Albumen	1 ounce.
Rain water	4 ounces.
Iodide of potassium	2 scruples.
Bromide of potash	10 grains.

Filter through doubled linen for use.

No. 3.

Nitrate of silver crystallised	1 drachm.
Citric acid	2 grains.
Glacial acetic acid	1 drachm.
Distilled water	2 ounces.
Iodide of potassium	1 grain.

Filter before use.

No. 4.

Bees wax	2 drachms.
Camphine	2½ ounces.
Benzole	1 ounce.
Paraffin oil	½ "

Add ten grains of iodine and mix.

No. 5.

Albumen	6 drachms.
Iodide of potassium	2 scruples.
Bromide of potassium	10 grains.
Strongest liquor ammoniæ	8 minims.
Powdered hydrochlorate of ammonia	8 grains.
Distilled water	4 ounces.

Filter through linen after well shaking in a bottle.

No. 6.

Iodide of potassium	1 grain.
Nitrate of silver	11 grains.
Distilled water	2 drachms.

Dissolve, and add —

Distilled water	6 drachms.
Beaufoy's acetic acid	1 ounce.
Citric acid	4 grains.

Filter before use.

No. 7.

Pyrogallic acid	10 grains.
Beaufoy's acetic acid	2½ ounces.
Alcohol	1½ drachms.
Distilled water	5½ ounces.

Woolston, near Southampton,
July 20, 1859.

[As our contributor invites comment on the preceding, we offer a few remarks. The specimens sent, although faulty, as mentioned by the producer, indicate that paraffin oil may prove highly valuable in the paper processes: it not only renders the paper very transparent, but flows very readily, and is easily applied.

The belmontine oil is a preparation closely allied to the former, but is perfectly limpid, and much less offensive as regards the scent; it differs from it remarkably in one respect when under combustion, having less illuminating power, and greater tendency to produce smoke and char the wick; it is, therefore, well worth a trial; the qualities named prove a variation in composition, notwithstanding its general resemblance to the first-named oil.

The appearance (like a dull daguerreotype) named, under certain circumstances, is readily accounted for. A slight deposit of silver has been formed *on the back* (which was also sensitised) in that molecular condition most frequently seen where development has been pushed by slow action. It is by no means uncommon.

We notice that, as a rule, the most intense negatives (of those sent), as seen by transmitted light, are taken upon thick paper (Turner's negative), and these exhibit best detail. There is, however, one exception noticeable — the paper is *thin*, but *hard and heavy*, as if it had undergone considerable pressure in the manufacture. It is very free from granulation, and we consider it the best specimen of paper for this purpose. It is labelled "July, 1858 — Nos. 1, 2, 3, 7 — exposed from one to two minutes — developed with pyro — rewaxed."

We will now venture to suggest a course of proceeding, based upon the above, which we think calculated to produce good results, with but moderate labour.

Procure paper thin, hard, and above all, free from grain; albumenise it in the same way as for ordinary positive printing, but *instead* of the salt usually employed with the albumen, use the following, viz —

Albumen	1 ounce.
Liquor ammonia	10 minims.
Iodide of ammonium	4 grains.
Bromide "	2 "
Chloride "	1 grain.

Dry before a fire. When dry, immerse in M.D.'s solution **No. 1**, and again dry. Sensitise on the albumenised side only with solution **No. 3**, and proceed as directed in M.D.'s paper.

By this arrangement the impression will be on the albumen only, and but little affected by the grain of the paper, which will also be rendered strong and tenacious, consequently not liable to tear in washing.

Since the preceding was in type we have received the following note, with specimens, from our correspondent. Again we notice that the paper containing most "body" gives the best results— (some of Turner's old "Chafford Mills") but the transparency of the paper after the use of the belmontine oil does not seem so great as when paraffin oil is employed.—Ed.]

Dear Sir,—By the earliest opportunity I take the liberty to transmit for your notice the first negatives taken with belmontine; that marked No. 1 being the first, and that marked 2 the second, &c. The second was, I think, over-exposed and not kept floating long enough on the water before developing. Canson's has a positive appearance by back view in water. I append the formula used, and am sorry that time does not permit me to send you more. It is my wish to try one or two other plans, and if sucessful may, provided you do not object, hand you their results. These pictures should have further washing in water; I am obliged to

leave attending to them, and venture to send them but imperfectly finished. The pictures are cleaner with the belmontine, which seems to me to be a pure kind of paraffin. Your devotion to science I fear must inflict upon you many rude attempts at photographing for inspection. Pray excuse this hurried scrawl, and with all due apology allow me to remain.—Yours, &c. M.D.

Belmontine	1 ounce.
Iodide of Ammonium, crushed	of each 5 grains.
Iodine	of each 5 grains.

Mixed—reposed for nine hours.

Sensitised by formula No. 6. Developed by formula No. 7.

Time—No. 1. Three minutes, very dull light after heavy storm, 11.30 a.m. No. 2. Two minutes, a little gleam of sun for about fifteen seconds. No. 3. Canson's: two minutes, bad. No. 4. Two minutes, dull but not so much so as when No. 1 was taken.

Am afraid there was some hypo' solution with arg. chloride mixed with the simple hypo' used in all the pictures sent. Unless more washed they may discolour. The hypo' darkens considerably on twice using.

IMPROVED FORMULA FOR DRY COLLODION AND FOR ALBUMEN NEGATIVE PROCESSES.

By C. J. Burnett.

Salt your collodion with mixed iodide, bromide, and chloride, of *ammonium*. The iodide and bromide may be used in the usual proportion, and the chloride as an *addition* in the same atomic proportion as the iodide. However, my impression is that a larger proportion of bromide is advisable. Sensitise as usual, wash away free nitrate with *pure* or slightly ammoniated water, and then coat either *à la Fothergill* with albumen, or else coat with a weak alcoholic, not ethereal, solution of cerĕoline or gum-lac, containing grape-sugar, which tends to facilitate after operations. Keep, expose, and develop as usual.

A mixture of *gum-arabic* (or gelatine) with grape sugar (or glycerine), makes a better protective coating for the collodion, the relative proportions being varied according to whether the plate is to be used dry or moist.* As to variations in the salting, the three calcium salts, iodide, bromide, and chloride, are all soluble in collodion, and may *together* be substituted for those of ammonium. The cadmium-chloride is also soluble in collodion (especially when strongly alcoholic), and may be used either with its bromide and iodide or with those of ammonium. It must be recollected that when used for the preparation of dry plates, made in a large quantity at a time, and out of which the soluble decomposition-products are washed, the stabilities of the different iodides and bromides deserve much less consideration than where photographers are dependent on the keeping of fluid collodion for a long time in bottles.

I have a high opinion of the value of this and the allied processes conducted on waxed or gutta-percha-prepared, or paraffin-prepared paper, as long ago recommended by me, particularly when using the collodion containing a very large proportion of alcohol, to the value of which I was, I believe, the first to call attention, in your Journal of May 15, 1858.† The great advantage of the rarer alkalies named or alluded to in my pamphlet is, that they permit us to introduce phosphoric, iodic, bromic, and the organic acids into the collodion, from the greater solubility of their salts.

In working on the system I especially recommend with oxygen salts, or chloride, of ammonium or trimethylamine, &c. IN *the collodion*, so as to leave salts of silver oxide or silver chloride in the film, instead of the usual free nitrate; it is worthy of note that the exact condition of our sensitising bath as to neutrality, &c. &c. becomes of much less importance than it used to be on the old system—no small gain in point of convenience.

As to our iodide, bromide, and chloride plates in the formula which I have given, *oxide* of silver being still a desirable requisite in developing, the best plan seems to be, after exposure, to immerse them in a nitrate of silver bath for some time before they are put into the ferrous, gallic, or pyrogallic developing bath, or, instead, to immerse them (after exposure) first in a nitrate of silver bath, then in a tartrate, oxalate, or phosphate of soda bath, to precipitate the silver oxide and prevent its being washed away into the developing bath, and then transfer to the developing bath, which need not in this case contain any silver.

I believe that the plan which I see has been lately adopted by several photographers, of adding chloride of ammonium to the washing water is, though no doubt useful, still so far a mistake, the chloride is infinitely better introduced, as I have recommended, in the *collodion* itself.* N.B.—It will not do to employ any of the potassium or iodine salts in iodising or bromidising this collodion, or we are apt to have a precipitation of the chloride of the base in the collodion.

A similar mixture of bromide, iodide, and chloride, would appear to have some advantages in salting albumen for the ordinary old albumen-film processes on glass, or on wax-paper, and it would appear that the addition of a little caustic ammonia to make the albumen flow more readily on the plate or wax-paper, or gutta-percha (a similar paper), may be very useful.

For Albumen Negatives, on glass or on waxed-paper (or on paper prepared with paraffin, gutta-percha, gum lac, amber, copal, or other resin or allied substance in solution).

Prepare the albumen with iodide and bromide of ammonium or potassium as usual,† and then add to it in proportion to every 166 grains of iodide of potassium (a similar quantity of iodide of ammonium) any one of the following:—

1 eq. Common phosphate of soda
223 grains Dipyrophosphate (crystals)
1 eq. Metaphosphate (glacial)

Sensitise as usual, wash in plain water and dry. Common salt also may be added.

* While giving the other as a view well worthy of consideration, I considered the action of the vegetable matter, along with the nitrate of silver, as a more probable explanation of the results obtained. My experiments with *gum* and gelatine in the silver bath were (though interrupted) commenced precisely to see whether, not only with, but without bromides or iodides, or chlorides, it might not be possible to develop a picture, after washing with water (or *slightly* ammoniated water), with the ordinary developers, or the following solution:—

Water	1 ounce.
Tartrate of ammonia or potash	60 grains.
Sulphate of iron or manganese	10 „

Liquor ammoniæ till fluid begins to smell.

And their object was to show whether the nitrate of silver could not be made to act, under solarisation, towards these soluble vegetable matters, precisely as ferric or uranic nitrate, or bichromate of potash, or certain other salts appear to do.

The metallic silver hypotheses would require to prove it, to take a sheet of prepared paper, expose one-half, keep the other in the dark; analyse both, beside the preliminary experiment of showing that even an alkaline silver solution, containing *also* manganous or ferrous sulphite, was unable to develop an image on it.

One palpable *prima facie* improbability of the metallic hypothesis is this, that while even pure white substances, when very finely divided, become apparently black, witness the black cavities found in quartz and plated metals in a state of very fine division, &c., very generally become either black, purple, or darker in colour. We have, as far as I know, no instance at least of any simple substance which becomes lighter in colour when finely divided, though black marble, slate, &c., do certainly become lighter in colour when pulverised. Still there is no absolute *à priori* reason why a finer pulverisation may not produce white again. Recourse should thus far be had to testing the image, first for silver, second for *iodine*, with starch and nitric acid (or nitric acid alone on a French paper?); and thirdly for nitric acid, with sulphate of indigo.

† Either pure collodion or collodion containing also resin cereoline or paraffin being employed. I am inclined to think that the introduction of a little alkali, forming an alkaline resinate, and after immersion a resinate of silver oxide, into this collodion might be an advantage. The resinates of silver are soluble in alcohol but *in*soluble in water.

* The cyanides, ferrocyanides, and the other various complex cyanides should be tried in the wash water.

† Say two equivalents of iodide to one of bromide.

PHOTOGRAPHIC VISITING CARDS.

The fashion of photographic visiting cards continues to spread more and more every day. The skill of the artists who devote themselves to this *specialité* is great, and tends vastly to popularise it. The original form under which the photographic visiting card appeared placed the portrait in the centre, with or without the name in the lower margin. A specimen before us consists of a visiting card, of the usual form and dimensions, bearing the name and address in the ordinary way, only in the corner where titled persons usually place their crest and arms the engraver designs a little frame, no bigger than the stone of a seal-ring, within which is placed a portrait, almost microscopic, but quite recognisable.

These portraits are sometimes taken full length, and, according to the fancy of the original, the attitude and expression may be infinitely varied. A morning call, a visit of ceremony, congratulations, condolences, return to town, or departure, every form of visit has its appropriate photographic expression.

M. Delessert, the amateur who originated this idea, has hit upon a happy expedient connected with positive printing. While travelling, his servant, who occupies the "dickey" of his carriage, sat with folded arms, idle, thinking, probably, only of mischief. Now, before starting on a journey, M. Delessert places in his hands a printing frame and a negative, with a portfolio of sensitised paper, and employing the roof of the carriage as a working bench, he prints his proofs as he goes along, without fatigue or disturbance: thus at once occupying his hands and his thoughts, and developing in him a feeling for art. The idea is certainly very original and ingenious.

M. Delessert, who is no less skilled as author as well as photographer, has had his travelling carriage fitted up as an atelier—so compact and convenient, that even, when in town, he prefers it to any other. We hope to be able soon to describe this gentleman's labours at the hospital of Lariboisère, which give us a very high notion of what photography can accomplish in its applications to medicine.—*La Lumière.*

NOTES OF A PHOTOGRAPHIC TOUR IN THE HOLY LAND.

No. II.

PHOTOGRAPHIC operations are as attractive to the popular mind as a sugar-cask is to the flies. No matter where you plant your camera, on barren moor or sedgy vale, in a deserted village or a ruined city, in the desert or by the sea-shore, out of reach, as you suppose, of human ken, and are hugging yourself with the idea that you are alone, when straightway up pops one head and then another. Where they come from you cannot guess; they seem to grow out of the earth like mushrooms. When I put my head under the focussing cloth there was no human biped in sight except my dragoman, who looked with silent awe at my mysterious operations. When I withdrew my head, after obtaining a satisfactory focus, I found myself the cynosure of neighbouring eyes, to the extent of some sixteen wild-looking Bedouins, arranged in a semicircle, at about ten paces distance. My surprise was so great that I lost my presence of mind, and I suspect my countenance exhibited some tokens of fear, although I was not afraid, oh no! not at all, though I did look round for John. I suppose that, seeing my confusion, they concluded I was after no good, and after holding a consultation among themselves in (to me) an unknown tongue, as quick as thought the strongest and boldest of the gang rushed at my camera, lifted it up, tripod and all, and quickly strode away in the direction of the city, while the others seized every thing lying around and followed him. I turned to my dragoman, but he looked on quite unconcerned, as if what occurred was a matter of course. My first impulse was to cry "stop thief!" but a sense of the absurdity of such a proceeding soon came over me; so I made up my mind that the best thing I could do would be to follow on and see the game played out. The rascals never once turned their heads to look at me, but kept on their way with quickening pace. I had but one hope — that we might meet John, who had gone early in the day to explore the city.

In about twenty minutes the city was reached; the party halted at a bazaar, while one of them moved off, as if in quest of something. We were soon surrounded by some fifty half-naked citizens of Gaza, who divided their attentions between the camera and myself. My stock of Arabic consisted of one word — *Bekam*, which, being interpreted, signifies "how much?" Seeing a basket of oranges for sale near where I stood, and being exceedingly thirsty and choked with dust, I essayed my linguistic skill. It is all very well to be able to ask a question, but it is also necessary to understand the answer when it is made. *Arba* was just as intelligible to me as *ouahed*, so I did not know what to make of my answer when I got it. I then tried with my fingers, but with no better success. The Arab cannot interpret signs made by any other nationality. My attempts to make myself understood were received with shouts of derision. It was but too evident that, in obedience to the prophecy, the king had long ago perished from Gaza.

Matters seemed to be getting critical. I expected nothing less than that these gentlemen would treat me as mischievous boys frequently serve a stray dog:—tie, not a tin kettle, but my camera, round my neck, and chase me through the city, running "a muck." And I verily believe to this hour that such was their intention.

I gasped, in horror and despair, "Where's John?"

A sudden movement behind me, a turning of all eyes in that direction, caused me involuntarily to turn my head also. O welcome vision! There was good John, his herculean frame looming up above all the rest, with one hand gripping the throat of one unbeliever, and the other grasping the shoulder and holding at arm's length another. With a jerk he sent them both reeling; during their course, they overturned all they came in contact with, and soon some half-dozen of my foes were lying prone on mother earth. This style of argument seemed to have a very salutary effect: the living circle, which had grown uncomfortably narrow about me, immediately took a considerable expansion, and I could breathe more freely. Meanwhile, John had drawn a revolver from each of his side pockets, one of which he handed to me, keeping the other himself. "Don't fire," said he, "before I do; we are good for twelve shots, if you keep cool."

I was not very eager to shed a fellow-creature's blood, and only the certain prospect of destruction would have prevailed upon me to pull a trigger. I flattered myself that the sight of the weapons would have a salutary effect upon our foes, and check further aggression on their part. There was a parley. John thundered out his anathemas upon the Moslems, who sneaked away behind each other as they best could, when lo! "Room for the Governor!"

The Pasha, in the nick of time, came to the rescue. Finding myself in the presence of this worthy functionary, I bowed profoundly to this degenerate representative of the decayed royalty of Gaza; the representative bowed to the ground, placing his hand on his breast, chin, and forehead, in the most approved oriental style, to signify the depth of his degradation. After a volley of suppressed grunts of profound admiration and respect, mingled with "*Salaam Aleikoum*," the Governor waved his hand to disperse the assembly, and backing up against a shop front, gathered up himself and his robes upon it, and motioned us to a seat on the opposite side of the narrow street. We took possession of two of the little shelves, which I suppose I must in courtesy call shops, and then came pipes and coffee! Heaven only knows where coffee comes from in such places: you might suppose the Pasha carried a portable coffee-shop about with him. No matter where he is or where you meet him, in the street, in the desert, on the mountain, down he sits, and you sit down, and forthwith the tiny cup of coffee, aromatic, glorious coffee, Mohammed's wine! comes smoking hot to burn your lips and soothe the nervousness you naturally feel at the illustrious presence in which you find yourself.

I stated the case to John, and John related it to the Governor, with becoming indignation. That worthy functionary was incensed at the treatment the Howajjis had received. The offending culprits were led forth, and we were asked what punishment we wished to be inflicted upon them. Thinking they had acted from mistaken zeal, I begged they might be forgiven, on condition that they carried back my traps to the place they had taken them from. As soon as this sentence became promulgated, a shout of triumph was raised; my camera was shouldered and already on its way back to our camp, when I suddenly found myself lifted from the ground upon which I was standing, and hoisted upon two men's shoulders, with a mob of wild, howling, dark-visaged attendants madly capering around.

Talk of Eastern gravity: it is the gravity of a boarding-school miss in presence of the lady who teaches her "deportment." See the same prim miss at her romps! The Arab, under the influence of excitement, is more than a match for any uncaged animal.

Fortunately my traps sustained no injury. My losses were confined to a sheet of waxed-paper. Some inquisitive Moslem had opened the slide, and saw — nothing!

Next morning we dismissed the camels with which we had crossed the desert, and hired horses and mules. In the cool breeze of early dawn our cavalcade rode down the Zim Zim to Askelon, on the sea-shore, to the north of Gaza.

I quitted Gaza with reluctance. Its high antiquity had an unspeakable charm for me. It must have been one of the earliest cities of Palestine, for it is mentioned in Genesis with Sodom and Gomorrah. As the southern barrier of the Holy Land, it was always held as a place of some importance. It stood in the highway of the armies of ancient days: every conqueror who marched from the north into Egypt halted at Gaza. Cambyses took it. Alexander spent five months before its walls. The soil around is fertilised with human blood, which in every succeeding century has been poured out upon it, serving to nourish the luxuriant olive, which thrives and grows rich around.

Askelon, no less celebrated in modern as in ancient history, was once a great city. The ruins of its quays and wharves and breakwater, bear witness to its departed greatness. But now it is only a miserable village, destitute alike of trade, commerce, wealth, and almost of name.

We pitched our tents amid the ruins of the ancient city, and took our dinner on the sea-shore; cooling our wine in the hollow of a stately carved capital, into which the crisp foam dashed at every fifth wave. All the gallant deeds of Godfrey and of our brave Richard on these hills and in the valleys rushed into my memory. No more gallant deeds in the world's history are recorded than were done for the Cross and the Sepulchre on the fields of ancient Philistine glory. As I slept at night on these fields I could fancy myself one of Richard's host, and repeople the scene with the noble forms of the Crusaders who lie enshrouded in the dust beneath my feet.

We slept to the lulling sound of the surf, and rode next morning by way of Ashdod to Ramleh. Ashdod was the city to which the Ark was carried by the Philistines, and which suffered so terribly the curses of an offended God for their sacrilege. D. T.

Meetings of Societies.

LIVERPOOL PHOTOGRAPHIC CLUB.

THE usual meeting of this Club took place on Tuesday evening last. Although the last three meetings have been but thinly attended (probably on account of the favourable state of the weather for out-door operations), the interest is fully maintained.

Mr. FORREST exhibited six views taken by the turpentine waxed-paper process, by Mr. Hooper, of Manchester, which were much admired for their artistic selection and excellence as photographs, the only drawback being the amount of exposure required.

The Rev. Mr. BANNER exhibited some exquisite stereoscopic pictures taken by the Fothergill process. He stated that his operations had been attended with much more uniform success since he had adopted the one-grain washing bath; and by the advice of Mr. Shadbolt he had also materially reduced the proportion of albumen, using one part to four of water with great advantage. The addition of the chloride to the gum solution had also given in his hands excellent results, with a much shorter exposure.

Mr. KEITH exhibited and explained a very neat stereoscopic camera, sent by Mr. Newton. The camera slides along a bar about fifteen inches long, moving upon a centre, and the necessary degree of convergance is shown by means of an index and scale upon one end of the table. He also reported very favourably upon one of Derogy's lenses, which he had procured for a customer, having tried the various combinations, and found them fully to warrant the favourable opinion previously published in THE PHOTOGRAPHIC JOURNAL. He strongly advised all photographers using wet collodion to put their apparatus upon wheels, and stated that the 12 × 10 pictures exhibited by him upon a previous occasion had all been taken in the combined wheelbarrow tent which Mr. Brown had sent to him to try.

A MEMBER called attention to the disgraceful extent to which Sunday photography is practised in Liverpool. On the preceding Sunday he went out to judge for himself, and in a walk through a limited portion of the town he found TWENTY-SIX places of business fully open without the slighest attempt at concealment. The subject was one in which the credit of all engaged in photography was concerned, and he thought it a subject fully worthy of the attention of the Club.

Mr. FORREST, while fully admitting the importance of the subject, thought that it was not one in which the Club as a Club could move, but as it was certainly illegal, the power to put a stop to it lay entirely in the hands of the police. In Leeds, by the combined efforts of the magistracy and police, it had been entirely put down. He was glad the subject had been broached, and requested that the report of the discussion thereon should be forwarded to Mr. Shadbolt.

After an interesting discussion, and the exhibition of numerous specimens, the meeting separated.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

WE are glad to find that this as yet young Society progresses favourably, the number of members increasing, and many candidates for election are expected to be on the list by the next meeting, which is fixed for the 20th October next. This is no more than might have been expected from the fact that the officers and members of committee are all practical men. As the name of one gentleman was accidentally omitted from the copy supplied to us on a former occasion, we give the whole again complete, viz.:—

President — The Rev. F. F. Statham.
Vice-President — Mr. W. Ackland.
Hon. Secretary — Mr. A. H. Wall, 90, Cannon Street, City.
Treasurer — Mr. F. Howard, 5, Studley Terrace, Stockwell.
Committee — Messrs. Hannaford, Hervé, Clarke, Leake, Sen., Cotton, and Leake, Jun.

Practical Instructions on Coloring Photographs.

By ALFRED H. WALL.

CHAPTER III. *(Continued).*

Cobalt Green — Prepared from cobalt; permanent both in oil and water; very pure, but of little power; works well.

Sap Green — A most agreeable, clear, transparent colour, prepared from vegetable sources; much used, and working well in both oil and water, but, alas! fugitive.

OF PURPLE PIGMENTS.

Purple is nearly related to shade, of which it is very frequently the representative, although poets have associated it with imperial pride and royal grandeur: hence, perhaps, the vulgar idea of purple is by no means correct, but rather tends to that of crimson as being the most gorgeously suggestive of regal splendour; purple, however, has a solemn grandeur of its own, very characteristic of the mingled awe and reverence commonly animated by the consideration of royal attributes. Purples are generally compounded by the painter himself during work; consequently, I shall describe but two of these pigments, viz.:—

Madder Purple — A very rich, beautiful pigment, permanent, of good power and body, and working well in oil and water.

Purple Lake — A very bright colour, but fugitive; prepared from cochineal.

OF ORANGE PIGMENTS.

Orange is a very warm and splendid colour, suggesting light and warmth to the mind; it comes prominently forward* in a picture, and is associated with gaiety, cheerfulness, and splendour. Orange pigments are not numerous.

Orange Chrome — Chromate of lead, a beautiful colour, but it does not stand very well; is used in both oil and water. A similar preparation is sometimes called "*Mars Scarlet.*"

Orange Vermilion — A very eligible colour in oil and water, but works badly in the latter, in which a little gum should be added to it. It is permanent and of great use.

Orange Ochre or Spanish Ochre — A durable and useful pigment in oil or water.

Burnt Sienna — A sober semi-transparent colour, hardly to be called orange; although generally classed with such pigments, it is raw sienna burnt; is quite permanent, and is very generally used both in oil and water.

OF CITRINE PIGMENTS.

Citrine, or citron pigments, being broken yellows, represent in a minor degree the sentiments associated with yellow. Original pigments of this class are but few in number.

Brown Pink — A vegetable lake of a fine rich colour, very transparent, and working well in both oil and water, although it dries badly in the first; is fugitive.

Raw Umber — Another of the honest old ochre family, very eligible in both media.

~~*Bistre* — A rich colour of great service in water, but drying very~~ slowly in oil; prepared from the soot of beechwood.

OF RUSSET PIGMENTS.

The sentiments associated with "russet" may be briefly alluded to in the same manner as the preceding, viz., as partaking, in degree, of those belonging to that primary colour, to which it is most nearly allied.† The only pigment under this denomination which I use, is called

Madder Brown — It is a very eligible pigment, perfectly permanent, and universally useful in every branch of the painter's art; its preparation is indicated by its name.

OF OLIVE PIGMENTS.

Olive pigments are few and but seldom used.

OF BROWN PIGMENTS.

Brown is the name applied to a class of pigments greatly varying in character, according to the proportions of the colours which combine for their formation, but to which none of the denominations already given could be justly applied. These pigments are very numerous.

Vandyke Brown — A rich, deep, transparent brown earth, almost as celebrated as the painter whose name it bears. It is durable, works well in water and oil, but dries very tardily in the latter.

Burnt Umber — A pigment composed of manganese and iron, dries quickly in oil, works well in water, is perfectly durable and very useful.

Asphaltum — Used in oil only, and in this but little, although its clear transparency and beautiful colour are strong temptations to the painter; it is durable, but variations of temperature cause it to crack in every direction; factitious asphaltum is produced by the distillation of coal at the gas factories.

Sepia — Prepared from the sepia or cuttle-fish; very celebrated among water-colour artists, and deservedly so, as it washes beautifully, is perfectly permanent, combines well with other pigments, and for numerous purposes is pre-eminently useful. In oil, however, it is less used, in which it dries very tardily. Two different prepa-

* When I speak of advancing colours I mean such as would be seen more distinctly than others at a remote distance, or those which in any receding object would be longest in sight.

† This remark is of course applicable to all the colours and hues compounded from the three primaries, however broken they may be.

rations are sold, called respectively "cold" and "warm" (the latter being compounded with perhaps a little lake or other warm colour).

Indelible Brown Ink — A pigment very useful in water, as it is not disturbed after application by washes of other colours.

OF GRAY AND BLACK PIGMENTS.

Gray is the name of a class most nearly related to black. Grays are cold, retiring, and associated with shadow; their use, however, is great, and in every object of the painter's study grays (or greys) occupy no small space and attract no small share of his attention. The beauty and general effect of all warm colours derive force from contrast with gray, which also give it fresh value; the eye finds it soothing, and the absence of grays in a painting are signs of the artist's want of truthfulness.

Neutral Tints — Prepared chiefly for water-colour painting. As they are variously composed from other pigments, it would be useless to describe their properties.

Ultramarine Ashes — Very excellent pigments, possessing the same properties as the genuine ultramarine, being composed from the same material; they are extremely useful in obtaining the pearly tints of flesh, &c., in oil and water.

Black Lead (a form of Carbon) — From which, with white, may be compounded an exceedingly fine gray, pure and quite permanent, and possessing the capital quality of blending well with all other colours; used in oil only.

Ivory Black — Burnt bone, a fine neutral pigment, eligible for water and oil; permanent in both, but drying somewhat slowly in the latter.

Lamp Black — The soot of burnt resin, a very intense black; permanent; used in water and oil, but dries very badly in the last named.

Blue Black — Which I use in oil with my white, to destroy the tendency to yellowness derived from the vehicle employed; it exercises a preservative influence upon the white, both chemically and in the matter described; dries well.

Mineral Black — Used in oil for compounding grays; is perfectly durable, and dries very quickly.

Indian Ink—Used in water; is too well known to need describing.

As there are pigments fugitive under ordinary circumstances, but extremely serviceable, and capable of being rendered permanent by extreme or studious care, and as there are many colours which, although permanent in themselves, exercise a destructive influence upon other pigments, it is advisable that the earnest and conscientious art student should make himself better acquainted with the subject to which this chapter is devoted than in this series of articles I can hope or pretend to do. I would therefore recommend the study of George Field's *Treatise on Colours and Pigments*, published under the title of "Chromatography," from the preface of which I extract this paragraph, as a statement no less applicable to the present than to the time of its first publication:—

"Among the means essential to proficiency in painting, none is more important than a just knowledge of colours and pigments—their qualities, powers, and effects; and there is none to which the press has hitherto afforded fewer helps. There have appeared, it is true, at different times, several works professing this object, and most of our encyclopædias and books of painting treat cursorily on this branch of the art; but not only are these for the most part mere transcripts of the same obsolete originals, unsuited to the present state of the art,* but they are inadequate, irrelevant, and often erroneous, or untrue, as every one acquainted with the subject is aware."

But while strongly advising the student to make himself well acquainted with pigments, let him always avoid a class of painters who, as Shee says,

"Their time in curious search of colours lose,
Which, when they find, they want the skill to use!"

PROGRESS OF PHOTOGRAPHY.—The War Department has lately made arrangements for forwarding photographic apparatus to every military station in the empire, for the purpose of taking views of coast-lines, fortifications, &c., for transmission to head-quarters. Among recent applications of the art is that to the ornamentation of flat surfaces of salvers, urn-stands, cake-trays, and similar objects. The photograph is covered with stout glass, so closely fitted that, at first sight, the eye is led to believe that the ornament has been painted on the china or wooden frame wherein it is set.

* And more particularly to the requirements of photographic colouring.

Letters to a Young Photographer.

No. XV.

MY DEAR EUSEBIUS,

If ever I make another photographic excursion in the middle of July again it shall be at the Antipodes, where the thermometer ranges something under 90°. I think we have had a nice time of it truly. Like the weird sisters in *Macbeth*, when we met, it was 'mid thunder, lightning, and rain, to say nothing of hailstones as big as oranges. My face—bah! I am ashamed to look in the mirror; I look like a Red Indian, painted with red ochre for the war-dance. The cuticle, blistered by the sun, is all peeling off, and my hands are of the colour of burnt umber. My coat has got many holes in it, and so have my breeches, through scrambling under hedges for shelter from the pelting storms.

As for you, you seemed to like it; it was rare fun for you to get soaking wet to the skin, three or four times a day; but you are young, and can afford to laugh at the little miseries of life, and have no fear of rheumatism before your eyes; but my arms feel as if they had been stretched on a rack for four and twenty hours.

But when I look over my portfolio of the negatives we took I feel that there is compensation for all the inconveniences we have suffered. What splendid effects we got when a dense black thunder-cloud formed the background of our pictures! I fancy how the knowing ones will stare when they see Eusebius's productions in the next exhibition. One thing is yet lacking: a photograph of a flash of lightning, which, under auspicious circumstances, may possibly be obtained by Mr. Skaife's instantaneous process. I do not despair of obtaining a good representation of forked lightning, for I am sure some flashes we saw lasted nearly a second.

I shall now essay to enlighten you upon preservative processes and dry collodion, with kindred contrivances, which have for their object the postponement of the development, which, in the employment of wet collodion, must be effected immediately the picture is taken.

To retard or prevent the drying of the collodion film it is necessary to mix with it some hygrometric substance, or to cover it with a coating of the like nature. To any one familiar with the operations of chemistry, various substances possessing hygrometric or deliquescent properties will readily suggest themselves; the only precaution necessary to take being, that the preservative substance selected shall produce no chemical decomposition either in the nitrate of silver or the iodised collodion. A person unacquainted with the vagaries of photographers would naturally conclude, in looking over the list of substances proposed as preservatives, that photography was a section of the art of cookery; and a facetious friend of mine (not Erasmus) threatens to publish a half-crown book on "Photographic Cookery;" but I assure him there is one already, although it does not pass under that title.

First in chronological order among "preserves" stands, I think, nitrate of magnesia, a very deliquescent salt, but which, upon trial, was not found to answer the proposed object satisfactorily. Honey, suggested by Mr. Shadbolt, was a great improvement upon this salt, and notwithstanding the introduction of various other substances, it still remains the best for the purpose. Oxymel, which is a mixture of honey and acetic acid, found great favour for a time; but I could never become satisfied that it was better than honey, pure and simple. Some experiments I made with glycerine were so successful that I cannot understand why this substance has not been received into favour as a preservative agent. I attribute the cause of failure to the employment of a sophisticated article.

I do not think it necessary to enumerate all the substances which, like ephemera, have enjoyed their brief hour of existence: each was thought best by its inventor (!) But to show the infirmity of the photographic mind, I was challenged to mortal combat by one pugnacious individual, because I presumed to deny the efficacy of, or the necessity for, the "raspberry-syrup process;" but we have thus far done without it, and are likely to continue independent of it.

From the first day that I worked with collodion up to the present time, I have made it a rule to put into my nitrate of silver bath as much loaf sugar as I put nitrate, and I am sure I find my advantage in it, for I can sensitise half-a-dozen plates in advance, and expose them in the camera, without stopping to develop until all are ready. A sensitised plate, if left in a horizontal position, will keep in good condition an hour or more. Honey added to the nitrate bath proves just as efficacious. Honey and sugar in solution act in the same manner; the crystallising property of sugar is destroyed when mixed with nitrate of silver. A bath containing sugar or

honey must not, however, be exposed to the light or to the sun's rays, else the silver will be precipitated. Here is a formula I generally employ:—

Distilled water	10 ounces.
Nitrate of silver	5 drachms.
Acetic acid	2 "
Alcohol	3 "
Honey	2½ ounces.

(*Or* sugar, 5 drachms).

This solution will probably assume a yellow tint upon the addition of the honey: in that case add about an ounce of kaolin or fuller's earth, in powder, and filter. The collodioned plate must remain in this bath about a quarter of an hour, and, when drained, exposed in the camera, without washing. After exposure, the collodioned plate must be carefully washed in many waters, and then immersed in a simple nitrate bath for a few minutes before development. The development may be effected without this re-immersion, provided the washing does not remove all the nitrate of silver from the collodion film, or some nitrate of silver be added to the developing solution, which is made as follows:—

Water	10 ounces.
Pyrogallic acid	10 grains.
Acetic acid	1 drachm.

But what is called the "honey process" is different from the above, inasmuch as the honey is applied after the collodion film is sensitised and washed, by immersing the plate in a mixture of equal parts of honey and water. A plate thus prepared will retain its sensibility for several days. After exposure the plate is washed with water to remove the honey, and then developed in the usual manner.

Mr. Maxwell Lyte suggested a mixture of gum arabic and honey. The formula for his solution is —

Water	12 ounces.
Gum arabic	2 "
Alcohol	2 "
Honey	1½ "

The collodioned plate being sensitised, and drained as usual, it is placed upon a levelling stand, and as much distilled water poured upon it as will cover it. Pour off this water into a measure, and pour it on again, repeating the operation several times. Set the plate up on an angle on several folds of blotting-paper to drain, then pour on the solution containing the gum and honey. Pouring it on and off several times, as with the water, set the plate on an angle to drain, and leave it to dry. The exposure will need to be double that of ordinary collodion. Before development the plate must be washed, to remove the gum and honey.

Glycerine was proposed by Mr. Henry Pollock, in the proportion of ten drops to three ounces and a half of collodion, and, in the sensitising bath, one ounce of glycerine to every five ounces of water.

A second sensitising bath consists of eighty-five parts of water, fifteen parts of glycerine, and one part and a half nitrate of silver. The collodioned plate is first sensitised in the first bath, then immersed for a minute in the second bath, washed, drained upon blotting-paper. Plates thus prepared will retain their sensitiveness for a week. Before development the plate must be rinsed with distilled water; the developing solution is the usual pyrogallic acid. The sensitising bath is deteriorated very soon by the glycerine, and will require to be filtered and strengthened; it is therefore best to employ horizontal baths for sensitising, as they require a smaller quantity of the solution. The employment of glycerine has been perfected by Mr. Llewellyn, who operated with a pure sample of that substance.

I must also mention Mr. Maxwell Lyte's *metagelatine;* that is, gelatine brought to the condition in which it will no longer solidify or gelatinise. Metagelatine is prepared by boiling one drachm of gelatine in one ounce of water. When quite dissolved, add two drachms of water containing twelve drops of sulphuric acid; boil the whole for five minutes, and then set it aside to cool. This boiling and cooling must be repeated several times, until the liquid no longer becomes a jelly when cold; then the acid must be neutralised by the addition of chalk in powder, until it ceases to produce effervescence. A drop of creosote is to be added, to prevent mouldiness, and the liquid is filtered. Mr. Lyte then prepares a syrup as follows:—

Metagelatine	5 ounces.
Water	5 "
Honey	1½ drachm.

The collodioned plate is sensitised in the usual manner, then drained. Sufficient of the above syrup is poured upon it, and made to flow over the plate, then poured off. It will carry away with it most of the nitrate of silver; it must be thrown among the residues, and a second and a third quantity poured on, until the syrup spreads uniformly over the collodioned film. The plate is next allowed to drain and dry in the dark, and it will then retain its sensitiveness for several days. The exposure required will be double that of ordinary collodion; after which it is washed in distilled or rain water for a minute, and then developed and fixed in the usual manner.

Now, my dear Eusebius, I am not going to pronounce judgment upon any of the methods above described; each has, doubtless, its respective merits. I know that each has its partisans and advocates. It will be a delightful occupation for your ingenuity and industry to try them all, and let me know which you think the best. Give at least a week to each, else you may come to hasty and rash conclusions. There yet remains "dry collodion" proper; and the collodio-albumen processes will next engage your attention. Thus you will see there is work enough laid out for you to do, ere you can become "the accomplished photographer," armed at all points. When the claims of photography are fully recognised, I doubt not we shall see professorships established in our colleges and universities. When I see you installed in one of them, then shall I feel rewarded for all the care I have bestowed and intend to bestow upon you, and feeling my mission ended, prepare to depart in peace. I have not touched upon the æsthetic side of photography yet. The photographer requires not only the chemist's hand but also the artist's eye—a sort of sixth sense which is born with us, but which cannot be acquired, although, like the other senses, it may be greatly developed and cultivated.

Photographic Glossary.

Photogalvanography — A method of heliographic engraving invented by Paul Pretsch. A plate is coated with a mixture of gelatine and bichromate of potass, and exposed to the action of light under a collodion positive or negative. When afterwards washed with water the gelatine not acted upon by light is dissolved, leaving the surface in a state of inequality corresponding with the amount of action caused by the light. A mould is now taken from this in some plastic material, upon which copper is deposited by the galvanic or electrotype process, producing a plate or plates, from which any number of impressions may be printed at the copperplate press. A specimen of this art was given with No. 87 of this Journal.

Photolithography — A heliographic process by which the photographic image is obtained upon lithographic stone, from which impressions may be printed in the usual manner. It is the invention of M. Poitevin. The stone is covered with a solution of bitumen in ether, so as to leave a *grain* and not a varnish. Exposed to the action of light, either in the camera or under a collodion positive or negative, the bitumen becomes insoluble in those parts upon which the light has acted; the other portion is washed away with ether. The stone is then prepared in the usual way for printing, and inked, and if the operation has been carefully performed, will require no touching to yield good impressions. The process may be varied by covering the stone with a mixture of albumen or gelatine and bichromate of potass, and after exposure washing off the preparation, then proceeding to the inking, &c., as indicated above.

Photoglyphic Engraving — A process invented by Mr. Fox Talbot. It consists in coating a metal plate with gelatine and bichromate of potass, and exposing it to the action of light under a negative. The plate is not washed, but some finely powdered copal resin is sifted over it, and then melted by holding the plate over a spirit lamp. The object of this is to produce a *grain.* When cold the plate is acted upon by an etching fluid, which is composed of hydrochloric acid saturated with peroxide of iron. This liquid penetrates the gelatine where the light has not influenced it, but does not act upon those parts which are modified by the light. The etching is stopped by wiping off the fluid with a clean linen cloth, then rubbing the plate with a soft linen rag and whiting and water, to remove the gelatine. The plate is now ready for printing.

Pigments — The paints or colouring materials used in painting, frequently miscalled colours. Colour is the immaterial quality possessed by various material bodies which are termed paints or pigments.

Foreign Correspondence.

Paris, July 26, 1859.

MALBROOK is returned from the war; our swords are turned into reaping-hooks, and all goes merrily as a funeral bell. We have to mourn over lost friends sacrificed at the shrine of fiendish tyranny and ambition, over disappointed hopes and unrealised aspirations, and, like the tender snail, withdraw our heads again to bide our time. There is but one art—the art of war; but one science—the science of destruction. No invention recommends itself so promptly as that aimed against human life. The inventor of a murderous bomb, a destructive rifle, an annihilating cannon, is honoured and *fêted*. Your inventors of steam engines and life-boats may go and hang themselves; we can do without them.

Photo' was one of the busiest of the camp followers, and has come back laden with spoils. Solferino before the battle and after!—with a difference. Portraits of Generals, Turcos, Zouaves, Vivandières, adorn our albums—sad mementos of the dire necessity for war with its train of miseries! To-day I feel like the melancholy Jaques, and if the thermometer keeps on mounting, I shall soon become another Timon, and flee to the woods and rail there against mankind.

It is vain to look for much photographic novelty under the present state of the atmosphere. My ether bottles are all empty, and my collodion is gelatinised. I went into my *atelier* this morning very early, in order to prepare for a day's manipulating, but the sight that met me there prompted me to make a speedy retreat.

At the time parchment paper was introduced to the photographic world it was hoped and expected that it would be found extremely useful in photographic negatives. I cannot learn that it has been applied to that purpose yet. Meanwhile a little controversy has arisen as to who is the inventor of this curious substance. Its discovery has generally been attributed to Mr. Gaine; but M. Louis Figuier has put in his claims for priority, having discovered it, in conjunction with M. Poumarède, in 1846, and published it in a memoir on ligneous substances, in 1847:—

"We have arrived at the discovery of a new substance, which exhibits a very curious modification of ligneous tissues. It is the result of the primary action of sulphuric acid on lignin, wherein the resulting product precedes its transformation into dextrine.

"If a piece of bibulous paper is immersed in monohydrated sulphuric acid for about half a minute, and immediately washed in a large quantity of water to remove the acid and stop its further action, and then placed for a few moments in water containing a few drops of ammonia, a substance is produced which exhibits all the characteristics of animal membrane. When wetted it feels soft and greasy to the touch, like animal membranes soaked in water, and when pressed and glazed is very transparent. It will probably be found very useful in the arts.

"Analysis has shown the identity in chemical composition of this product, which we call *papyrine*, with lignin. Sulphuric acid, by its action upon the latter, causes it to pass into a new isomeric state; the action is therefore exactly like that effected in its conversion to dextrine."

It was in 1857 that Mr. Gaine took out his patent in England for *vegetable parchment*, which MM. Figuier and Poumarède had discovered and published ten years previously. The only difference in his method, if difference it can be called, consisted in adding a half volume of water to the monohydrated sulphuric acid employed by M. Figuier.

Mr. Warren De la Rue has come to the rescue of Mr. Gaine, and asserts that, although parchment paper may be obtained by following M. Figuier's formula of *monohydrated* sulphuric acid, it is due to Mr. Gaine to say that he has established the conditions necessary to obtain a material practically useful, the paper acquiring an astonishing cohesion when treated with a mixture of two volumes of monohydrated sulphuric acid and one volume of water. Mr. Warren De la Rue is convinced, by numerous experiments, that the only suitable proportions will be found to lie between the formula laid down by Mr. Gaine and a mixture of four volumes of sulphuric acid and one of water.

It is probably the great difference which exists between the products obtained by monohydrated acid and by diluted acid which explains, up to a certain point, how so interesting an observation has remained so long unapplied to the arts. It has taken no less than a dozen years to transform the scientific idea into a practical art, and establish it as a new branch of industry. Without the use of diluted acid it would be impossible to produce a single sheet of parchment paper.

To this communication Mr. De la Rue adds that he is ardently pursuing his experiments in celestial photography, and that he will soon be able to exhibit beautiful proofs of the stars.

M. le Comte Aguado has produced some very curious photographs taken from an elevation, so as to exhibit objects singularly foreshortened. Mr. Richbourg has varied the idea by taking vertical objects, such as the interior of the cupola of the Cathedral of St. Isaac, at St. Petersburg, which is painted by the Russian artist, Bruloff. J. P.

WAXED-PAPER PROCESS.—The progress of this important branch of the art of photography has been much impeded through the difficulty of obtaining white wax in a state of purity, than which few articles of commerce are more grossly adulterated. The articles used to adulterate wax are chiefly stearine and tallow. Their presence may be readily detected in the following manner:—Take one drachm of the sophisticated wax, and boil it for four or five minutes in one ounce and a-half of strong alcohol; set it aside for several hours to cool, then filter it. Upon adding some water to this solution, a flocculent precipitate will be thrown down if stearine be present; if the wax be pure scarcely any effect will be produced in the solution. By this means one per cent. of stearine may be detected. Tallow may be detected thus: take half a drachm of the wax and boil it for three or four minutes in three and a half ounces of a solution of caustic soda containing six grains of pure hydrate of sodium (NaO, HO); then saturate the mixture with a weak acid, and warm it. The wax will separate, and may be removed when cold, dried with bibulous paper, and weighed. It may then be treated with alcohol as above, and separated by the addition of water. This process will detect as little as one per cent. of tallow.

Correspondence.

PLATINUM AND PALLADIUM.

To the EDITOR.

SIR,—I forgot, or omitted, I believe, to mention in my last letter to you that, though not alluded to, I think, in my old articles in your Journal, as especially with reference to negative processes, I, at one of our meetings here, called attention to the advantages of both *platinum and palladium for toning negatives, both on paper and glass*, connected with the fact of the photographs so toned *transmitting* much less blue light than those toned by gold. I rather think (though I have not been able to lay my hands on the number) that the toning with palladium was mentioned in a letter of mine in the *London Photographic Journal* also, of some months back.

Did I mention that I had used *alkaline* palladium toning baths also? I am amused at the photographers already running wild after palladium here, though it was offered to them last winter by me, two bottles of it, as well as the metal, having been taken to the Society's meeting, and no one would have it; and I gave one of the identical bottles of it three days ago to one of our members, who was making inquiries about the "NEW *metal*," for toning.

The price per ounce of palladium, some £5 or £6 when I last inquired, is, as you will find noted in my paper, a serious consideration; but still we cannot, as I have pointed out, judge of actual experience certainly from this and chemical equivalents alone; and at all events, when used as a *developer* for the uranic and ferric papers, the palladium salts do seem to go very far. There the tint is generally brown or black,* but when employed in toning there does seem a rather greater variety of tints given; still there is often such a tendency to brown, as might make palladium salts useful in modifying the tint given by gold alone. The brown tint of platinum toning might also be used in the same way. We may get also very good results by developing an uranic or ferric print with both gold and palladium, either mixed or separately, in succession, palladium reducing gold from its solution. Palladium prints are readily fixed by weak ammonia or even by plain water, differing in the latter from silver prints; and the ferrous salts may be called in as an aid in the palladium-developed uranic and ferric processes, just as they are in the silver-uranic and silver-ferric, this being exemplified in one of my palladium specimens sent to (but not admitted into) the Suffolk Street Exhibition. Another mode of producing pure palladium, and what is more important, *pure platinum prints*, is the treatment of MM. Beauregard and Sella's, or mine, or any of the other ink prints, with *alkaline* solutions of the platinum (?) and palladium salts. The same plan may be of course pursued with an alkaline gold bath, but to little or no advantage, the chrysotypes (Sir John Herschel's ferric and my analogous uranic) being so very much simpler processes. The salts of rhodium, iridium, and ruthenium, also deserve trial in this way. I am, yours, &c.

July 14, 1859. C. J. BURNETT.

* Palladium, like platinum, seems capable of giving either a brown or black, according to circumstances — say according to the salts used or according to the state of combination or freedom in which it is deposited. When deposited on black apparently metallic silver, or when complete reduction is proved by presence of ferrous oxide, there is a tendency to the black (probably the metallic) form of it.

MALTWOOD'S FINDER FOR MICROSCOPIC OBJECTS.

To the Editor.

Sir,—I imagine from your having given a description of Maltwood's Finder in your paper, that you might care to know a simple mode of recording the numbers, by which each square may be sub-divided into 5, thus:—Supposing the following figure represents the particular square, if the object should be in the centre of the square, write merely the figures $\frac{20}{30}$ but if it should be in the corner *a* write $\left|\frac{20}{30}\right.$ if in *b* $\left.\frac{20}{30}\right|$ if in *c* $\left|\frac{20}{30}\right.$ or if in *d* $\left.\frac{20}{30}\right|$

HIGH POLISH ON PHOTOGRAPHS. — TONING BATH.

To the Editor.

Sir,—Can you, or any of your numerous readers, inform me by what process that beautiful polish is given to those fancy boxes in which the drapers supply pocket handkerchiefs, &c.? It is, I presume, a preparation of gelatine, but how applied I am anxious to know, as I think, if applied to photographic prints, it would much improve their appearance if not tend to preserve them from fading.—Waiting for information in your next Journal, I am one of your subscribers from the first, J. M.

P.S.—Whose toning bath do you think is the best? I cannot succeed with Hardwich's.

Cockermouth, July, 1859.

[The brilliant polish mentioned is not good for photographs, as it affords no protection from moisture. It is produced as follows:—A plate of glass is cleaned perfectly, and placed in a horizontal position. It is then covered with clarified ox gall, in a very thin film. Clarified gelatine, dissolved in hot water, is then poured on, and allowed to remain till cold, and set moderately firm. The print is then laid thereon, face downward, and pressed closely; afterwards it is thoroughly dried, when the print, with the film of gelatine firmly adherent to it, may be stripped off the glass.

To produce a very brilliant varnish that *does* protect a photograph, the latter should be well sized with clear gilders' size, attached by its edges to a flat board, and then French polished.

Hardwich's toning bath is a very good one, and succeeds in our hands perfectly. We prefer, however, Maxwell Lyte's, as somewhat more simple.—Ed.]

To the Editor.

Sir,—Will you oblige me by kindly replying to the following queries:—

1. Will kaolin injure the nitrate bath for printing if kept always in it, and the solution filtered off when wanted, and afterwards returned to the same bottle?

2. In replenishing the waste of the nitrate bath for printing and the nitrate bath for sensitising will the original proportion of nitrate of silver to the ounce be sufficient, the consumption of silver being balanced by that of the water? or does the silver waste more in proportion than the water, and therefore a stronger solution become necessary?

3. If a stronger solution be indicated, in what ratio should it be?

Bristol, July 19, 1859. I am, yours, &c. MEDICUS.

[1. It will do no injury.

2 & 3. Both should be replenished with solutions fifty per cent. stronger than their normal condition, as it is an established fact, beyond controversy, that *more* silver is abstracted than the equivalent for the fluid removed, though the *exact amount* of surplus varies with circumstances.—Ed.]

ANSWERS TO CORRESPONDENTS.

We have received from Mr. Burnett a specimen of his platinum toning. It is of a rich and pleasant brown tint, and altogether very agreeable except for an opacity in the shadows. It is, however, upon plain paper, and the defect may be one rather of manipulation than essential to the process. The formula is—

Bichloride of platinum	6 grains,
Soda	60 ,,
Water	8 ounces,

the proof having been fixed in hyposulphite of soda and washed *prior* to toning. This we consider a great advantage.

T. A. B.—See a paper by Mr. Burnett in the present number.

Alfred.—The best way of purifying a salt is by crystallising it—once, or more times.

Brutus.—You will perceive by our present leader that we think as you do on the matter mentioned.

Jas. Inchbald.—Perhaps Mr. Mayall's magnesian iodiser will answer your purpose.

T. R. S.—A minim does not weigh exactly a grain. The imperial minim weighs 91-100ths of a grain (·91), and the fluid drachm 54.7 grains, not 60.

W. Woodward.—We always acknowledge the receipt of communications, &c. Yours only reached us on the 27th ultimo. That you mention as previously sent never came to hand. Notice in our next.

C. R.—Why did you ask advice of a contemporary if you have no confidence in its editor? Perhaps you are doing the same with us. However, although we frequently differ from him, we in this instance endorse the opinion you say he has expressed.

Sambucus Niger.—Somebody has been hoaxing you, or you are trying the same upon us. Elder leaves for removing nitrate of silver stains are about as efficacious as linseed, said to be so by a French operator.

Interiors—You will find a dry or the honey process *better* for taking cathedrals and other interiors than wet collodion; the exposure that is absolutely necessary involves at least a partial drying of the plate. We have seen an admirable interior on a large plate that was exposed for *two whole days*.

W. W.—Hydrargyri bichloridum is popularly known as *corrosive sublimate:* it is a deadly poison. Hydrargyri chloridum is known as the medicine calomel. The best French chemists regard *calomel* as a *sub*-chloride of mercury, and corrosive sublimate as the proto-chloride, which often gives rise to confusion in translations.

Double Iodide.—Iodide of silver is soluble in a *strong solution* of iodide of potassium—not so, or rather but slightly so, in a weak one; hence, if paper be impregnated with the former, dried, and then immersed in water, the *excess* of iodide of silver is *precipitated in the pores of the paper*, and causes the primrose colour. It is an excellent plan for preparing calotype paper.

James Otway.—The article on colouring is by the gentleman whose name is attached to it—not a practised author, but a thoroughly practical artist, constantly employed professionally in that way. We believe it to be the most genuine and valuable article of the kind that has appeared in any photographic publication. You need not be afraid to follow the advice there given—there is no "book making" in it.

J. T. Field (Leeds).—The blue tincture of litmus is regarded as a true salt, resulting from the combination of a mineral base with a red vegetable acid. When strong acid is added to this tincture its base is separated, and the vegetable acid set at liberty, which then assumes its natural colour—a bright red. But if it is acted upon by a weak acid, which removes only a part of its base, there remains a salt with excess of vegetable acid. The colour is then purple.

H.—Your annoyance arises, probably from the collodions you name having a slight *alkaline* reaction, and this may be increased by the accumulation of organic matter in your bath. Test the latter with reddened litmus, and if it turns blue add a drop of *nitric* acid, and test again. Should no alkaline reaction appear, *boil* your nitrate bath for half an hour in a glass vessel or a common glazed pipkin; when cool filter. It is possible that you may have to resort to both of these remedies.

T. H.—The pamphlet on *Photography in Colours* was only printed for private circulation; we will, however, endeavour to ascertain if Mr. Burnett can spare you a copy.

Instantaneous pictures on *wet* collodion we have recently adverted to in our correspondence more than once. Back numbers for the current year are to be had of the publisher: you will find all the information you ask for in them.

Instantaneous pictures on dry collodion has also been noticed, and we hope shortly to lay before our readers some information on the subject.

Querist.—1. The probable cause of failure is, that your nitrate of potash was *not dried* before adding the sulphuric acid, or that the latter was of insufficient strength. Use the same acid as before, but with an increase of twenty to twenty-five per cent. in volume, and well dry the nitre before mixing. 2. Iodide of cadmium five grains to the ounce. 3. *Very* slightly acid with acetic acid. We shall be happy to see you.

M. D. (Sandbach).—We thank you for your kind and complimentary note; our position certainly involves much labour and thought, and we do our best to smooth away the difficulties of those less experienced than we happen to be, but we are fully repaid when we find our efforts appreciated.

The letters alluded to by you are written by a thoroughly practical operator, though we do not always quite coincide with the views he holds, especially as regards *toning*. For this purpose we consider Mr. Maxwell Lyte's formula decidedly the best as well as the most economical that we have used. That given by Mr. Burnett in our last also is theoretically perfect, but we have not personally tried it.

In Mr. Maxwell Lyte's formula one of the chief points to be attended to is to be sure that the chloride of gold is neutralised by carbonate of soda (forming thus a double chloride of gold and sodium) before mixing with the phosphate of soda. Keep a normal gold solution of the strength of eight grains to the ounce, one drachm then contains a grain of gold, which is ample for toning two large sheets of Canson's paper $22\frac{1}{2} \times 17\frac{1}{2}$ at least. Always mix your toning bath just before use, mixing only as much as you require, and we will answer for it you will not fail of suc sess with either plain or albumenised paper.

Have nothing to do with either iron or sulphur toning. For plain paper proofs we prefer Hollingworth's paper. You can obtain exactly what you want in albumenised paper from Mr. Spencer, Gold Hawk Terrace, Shepherd's Bush, and probably from others. What Mr. Spencer calls *new French paper* is what you appear to be seeking.

Received.—"J. B."—"C. J. B."—"M. D."—"O. G. R."

Errata.—In letter "On Development," line 4, for "*style*," read state. Line 8, for "*impenduelle*" read "imponderable." Line 9, after *actinisation*, omit the comma.

THE PHOTOGRAPHIC JOURNAL.

No. 100, Vol. VI.—AUGUST 15, 1859.

At the last meeting of the Liverpool Photographic Club a subject brought under consideration was rather pointedly referred to our special notice, we, therefore, feel bound not to pass it over in entire silence as we should have preferred doing, because entertaining, as we do, very great regard and esteem for the gentlemen forming that body, we certainly differ in opinion from the sentiments which the majority appear to hold on the point in question, unless we have misunderstood the same. The subject in question was that of Sunday trading in photography, a practice apparently somewhat prevalent in Liverpool, and one which many of the members considered it to be incumbent on photographers generally to oppose by repression.

In such an opinion we cannot coincide; we are opposed to coercive measures of every sort, except where any one transgresses the rights of his neighbour.

Respecting the theological view of the question, of course the pages of this Journal would not be a fit arena for the discussion thereof, and we strongly approve the decision of the meeting that, *as a club*, it was not its province to interfere.

As regards the legal aspect, if the law of the land be broken, it is surely the civil authorities who are the proper parties to redress the grievance if it exist; but we cannot admit that photographers, *as such*, have any thing whatever to do with the matter, and we have only noticed it now out of respect to the gentlemen who desired that our attention should be called to it.

British Association for the Advancement of Science.—Aberdeen Meeting, 1859.—We are requested by the local secretary to state, that in consequence of the suggestions made in our last, while framed and glazed photographs will be preferred by the promoters of the photographic exhibition to be held in connexion with the Association, they are also prepared to receive for exhibition unglazed photographs, simply mounted on cardboard. We feel convinced that this is a prudent concession.

In consequence of a sudden and severe attack of illness we have been obliged to avail ourselves of the assistance of a friend in preparing the present number for press, and we have to crave the indulgence of our readers for the consequent unavoidable absence of our usual preliminary remarks.

ON MODIFIED DRY PROCESSES.

By Major Russell.

Notwithstanding the great number of preservative processes now practised and recommended, I find them all more or less uncertain and imperfect. The collodio-albumen seems, on the whole, the least uncertain; but it has some disadvantages, of which, perhaps, the worst are, the liability of the dry albumen surface to contract stains from scum on the bath, the tendency to fogging which the plates sometimes show, and the difficulty of avoiding blisters. Fothergill's process has the advantage of admitting the use of a more sensitive collodion, without producing blisters; but in my hands it has given more uncertain results than the collodio-albumen.

The stains on the surface of the collodio-albumen plates can scarcely be avoided in some states of the bath; however carefully it may be filtered, a scum is formed by dipping the first plate, which stains the subsequent ones. The fogging seems to be produced by some soluble impurity, caused by the action of the nitrate of silver on the albumen, and which is liable to spontaneous reduction, especially in hot weather. This impurity may be removed in great measure by copious washing, but enough usually remains to cause the distance in a landscape view to develop too dark to print with the foreground.

The gelatine process is free from these objections, but has others of its own. If a collodion, made very powdery by age or the action of an alkali, be used, the plates are very insensitive, but work well otherwise. On the other hand, if a sensitive collodion be employed, the film blisters and becomes detached from the glass. If, again, to avoid this, the gelatine solution be made very thin, then the film is not kept in a sufficiently porous state to develop well. To cement the collodion film to the glass, I have tried a solution of india-rubber in benzole; but it does not adhere to the glass sufficiently. The addition of a little wax makes it adhere better, but it then dries with a coarse surface like ground glass. Gelatine has been employed as a preliminary coating; but it is soluble in the nitrate bath, and would probably contaminate it. Unaltered albumen on the glass would also have an injurious effect on the bath by contact at the edges, if not through the collodion. In order to avoid all these evils, I have lately employed three methods of working, which seem to succeed equally well. I have not yet tried them sufficiently to recommend any of them with confidence; but, as a considerable number of trials have given no failures, the details may be of interest to others who are experimenting in the same direction. The collodion is made from pyroxyline, prepared by Mr. Hardwich's formula for the wet process, dissolved in rectified ether and alcohol not weaker than s. g. ·805, the alcohol being in as large proportion as will work, the exact proportion depending on the strength of the alcohol and the bath: the stronger the alcohol the more may be used, but the more alcohol present in the bath the less will be required in the collodion. Add to each ounce of collodion six to eight grains of pyroxyline, and iodide of cadmium and iodide of ammonium, in equal parts, with one grain to the ounce of bromide of ammonium. The iodide and bromide may be used in weights nearly equal to the pyroxyline.

The exciting bath should not be weaker than 40 grains to the ounce, and may contain at least as much alcohol of ·830 as water. I have used a bottle made in about this proportion for several months, and it remains in good working order. Should the excited film show lines in the direction of the dip, let it set longer and move from side to side *immediately after dipping*. If this is not sufficient, add ether to the collodion.

The albumen is prepared by beating up white of egg to a froth, which on subsiding is poured into a bottle with a drop or two of essential oil of lemon peel: this preserves the albumen well, and diminishes its tendency to form bubbles. For the second and third methods, presently to be described, the albumen is improved by adding one drachm of nitrate of magnesia to each ounce, and thus prepared it is as good as any for the first method. The nitrate of magnesia, if very alkaline, should be dissolved in a small quantity of water, and cautiously neutralised with nitric acid, or it may crystallise on drying. It must however be neutral or slightly alkaline, as an excess of nitric acid would coagulate the albumen. For use dilute the albumen with as much water as will make it filter well; about equal quantity is generally enough, but it may be used thinner. Almost any albumen will answer, either iodised or uniodised; but for the second and third processes it must not contain sugar.

First Method.—Coat and excite the plate, wash in two or three dishes of distilled water, then in a dish of pump water. These waters may be used for a great number of plates without being changed. Then pour albumen across the end of the glass, incline

the plate so as to pour off at the other end into a measure, repeat this once, then immediately place in a dish of common water and wash about to remove the albumen; leave in the water until as many plates as are to be prepared have been brought to this stage. If the albumen be left too long on the plate before washing it will produce blisters. Immerse in a bath of about 20 grains of iodide of potassium to the ounce of water and as much iodine as will tint it as dark as port wine. Keep some iodide of silver (in the bottle) that it may be throughly saturated. A minute's immersion is enough; place in a dish of common water and change occasionally, or wash under a tap until the colour is nearly removed; then pass through the same waters which removed the nitrate, to restore the sensitiveness, keeping the plate a few minutes in the first water. After a few minutes in the common water, wash under a tap for a few seconds, and rinse with a little distilled water. Pour filtered cold saturated solution of gallic acid two or three times over the plate, and set up on one corner on blotting paper to dry. Should the film split off on drying, dissolve a small quantity of white wax in the collodion. If too much wax be used the film will set in clots, but in small quantity it appears to do no harm. Should the film become detached in developing, when dry paint one-sixteenth or one-eighth of an inch round the edge with any quick-drying varnish.

Second Method.—Coat, sensitise, and was as before; coat with the albumen, set up on one corner to dry (without washing off the albumen); when as dry as it will become spontaneously, immerse in a bath of alcohol of moderate strength, containing some iodine and iodide of cadmium, and saturated with iodide of silver. The proportions are of no consequence, so long as the solution is of a deep red colour; wash well, immerse in the nitrate washings, and in common water, and wash with gallic acid, as in the first method. This plan, though rather more troublesome, seems to give a richer picture, and I have not yet found the film to blister.

Third Method.—Begin by coating the glass plate with the albumen; set up on blotting-paper on one corner to dry spontaneously; then dip in the alcohol and iodine bath, to coagulate the albumen; wash, and rear up to dry. When dry, polish with cotton velvet rubber, coat with collodion, sensitise, and wash as before. After washing with pump water, rinse with distilled water, and pour on and off two or three times a solution of twenty to thirty grains of dried metagelatine (Maxwell Lyte's), and three grains of gallic acid to one ounce of distilled water, and set up to dry. Artificial heat must not be applied to plates prepared with gallic acid until they appear quite dry, on account of the varying solubility of gallic acid at different temperatures. Gelatine cannot therefore be used. This process is quite as sensitive as the others and developes better, and I think gives a rather softer picture. To test its power of resisting blisters, I made some very thick collodion, with alcohol and ether in equal parts, which formed a dense creamy film, filtered and prepared a plate with it within an hour or two, using metagelatine, thirty grains to the ounce; it developed readily, and showed no tendency to blister. A solution of iodide of cadmium, thirty grains to the ounce in water, with as much iodine as will dissolve, coagulates the albumen well, but I prefer the alcoholic solution. This, as well as the alcoholic nitrate bath, must of course be kept air-tight when not in use. Albumen, after being acted on by iodine, appears to be incapable of injuring nitrate of silver solution. The same nitrate washings may be used day after day for all the above processes, without any ill effects; whereas ordinary collodio-albumen plates would soon cause the water to discolour, and give foggy pictures.

The solution of iodide of potassium and iodine is an excellent cleansing liquid: a dirty developing glass, if rinsed with it, and then with water, is more to be relied on than if cleaned with nitric acid of moderate strength. The iodine seems to render any deposit totally inert.

ON BLISTERS IN THE COLLODIO-ALBUMEN PROCESS.

By Egbert Moxham.

I have tried every kind of collodion sold, and a great variety of pyroxyline, but I have not often found a preparation which would give in its *normal state* a film of the kind required, except by long keeping, or where the ether and alcohol, or one of them, contained water.

Collodion prepared with *pure* ether, *i.e.*, quite neutral and concentrated, and pure anhydrous alcohol, is very slow in acquiring a porous condition. I have some now by me prepared in January, with iodide of ammonium, which has hardly changed colour, although kept on the laboratory shelf without any extraordinary precaution.

When the ether and spirit contain water, and the pyroxyline is good for the purpose, a porous film is attained at once, but there is always more of a tendency to crapy setting, which renders it good for nothing in a short time.

The only plan which I find succeed is, to get a pyroxyline (if I can) prepared at high temperature, giving what you call a "short film" to iodise with ammonium, and then to add a few drops of liquor ammoniæ till the film becomes porous, and to use a separate bath for the collodion. The use of ammonia, however, requires some precautions, for if added to the stock bottle its action continues always, and to such an extent that the collodion becomes extremely rotten in a short time. I find it best to have a small bottle in this state, and to add a portion of it to the quantity of new collodion required for immediate use.

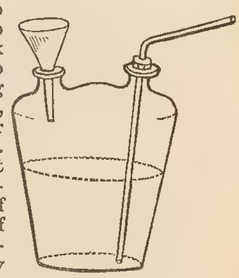
I find it also necessary to use a nitrate bath of full strength for collodion in this state: if the strength falls far short of 35 grains I get marks of all sorts on the plate, from irregular formation of the iodide. If these precautions, however, are attended to, the film is admirably adapted for the purpose. My experience leads me to believe that unless the albumen actually permeates the film so as to attach itself to the glass, blisters will be the general rule, so much so, that instead of submitting my collodion to the ordinary test I adopt the following:—I coat a plate and albumenise it as usual, dry and sensitise a second time, and remove it to a dish containing common washing soda in solution. If the film comes off easily with the finger and thumb and in flakes, the collodion is wrong; if, on the other hand, it requires a nail brush to bring it off the glass, I know that I shall never get a blister, excepting from a greasy glass. Nevertheless, there is one condition which it is necessary to observe, viz., that if the albumen be used *undiluted* the plate will require much working about in a bath before it will have fully permeated the film, and therefore I always use it very much diluted. If the porosity of the collodion film is merely superficial or showing a microscopic roughness, the albumen may attach itself to a great extent to the collodion; but unless the collodion in that case is very adherent to the glass the albumen will expand and raise the collodion in blisters when sensitised. You can never depend upon the process so conducted. According to my notions the following diagrams will represent the two cases.

No. 1. No. 2.

Atom of collodion. Atom of albumen.

In No. 1 you will never have a blister, because the albumen penetrates the collodion and fixes itself to the glass surface; in No. 2 you are most likely to get them from one or other of the following causes:—1st, the albumen detaches itself from the collodion; or 2nd, being firmly attached to the collodion, it pulls up the collodion film from the glass.

I use the following little instrument for washing off bubbles when the plate is albumenised in a dish.



It is simply a Woolf bottle with two necks. A bent glass tube, reaching to the bottom, is inserted through a cork into one neck, and a small funnel into the other, the filtered albumen being poured into the bottle by the funnel, and a muslin bag, if desired, to filter off any mucous threads in the liquid. The tube serves as a spout to direct a stream of albumen against any refractory bubble which will not wash off readily, and coming from the bottom of the liquid prevents the froth from escaping from the bottle so long as any liquid remains.

I feel sure that any one who will try a collodion sufficiently porous, albumenise in a bath with occasional movement, and use albumen with sufficient sugar or honey, will *never* find a blister in Taupenot's process if the plates are clean.

Before concluding these remarks I may mention that, although regarding a porous collodion as the key to success in this process, I have found lately that there is a quality of pyroxyline the very

reverse of the "powdery," which, when it can be met with, will give with anhydrous spirits a collodion film suitable for the Taupenot process. I cannot tell how it is prepared, but have occasionally met with it in French samples. Its qualities, when dissolved, are these: — it adheres to the glass with such extreme tenacity that on removal from the sensitising bath, the finger may be rubbed over the surface of the plate with considerable pressure without making the slightest impression. When the film is detached by the nail it comes off in a hard piece with irregular edges of fracture; it is perfectly structureless, and does not set ropy with the usual proportions of ether and alcohol. Collodion possessing these qualities will adhere to a well-cleaned glass with sufficient force to resist the expansive tendency of the albumen; but if the latter is applied without certain precautions there will be no combination, the collodion film being quite impenetrable, and consequently the albumen rises in blisters from it. It may be made to work as follows: the collodion must be thick and strongly iodised, and sensitised in a bath of full strength (say forty grains, otherwise the film will be uneven), and in the subsequent washings, instead of using distilled water, in the third cuvette a solution of iodide of potassium of ten grains to the ounce should be substituted. The surface of the iodised plate is slightly attacked, and sufficient of the iodide of silver is dissolved out of it to honeycomb it without perceptibly diminishing its opacity, excepting from an unusually prolonged steeping. The albumen will now adhere without any danger of subsequent detachment, and it may be applied equally well by pouring it over the plate, as often recommended, without the necessity of soaking in the cuvette.

[We think that the description of pyroxyline last mentioned by Mr. Moxham is prepared by a formula like that recommended by Mr. Hardwich, containing three measures of oil of vitriol to one of nitric acid, with the largest quantity of water possible. The product is not entirely soluble in ether and alcohol, and the collodion is very horny and adhesive.—Ed.]

ON IODIDE OF MERCURY IN THE COLLODION FILM.

By T. F. Hardwich.

(Continued from page 185.)

The following table, showing the effect of mercury on the darkening of chloride of silver, has been given to me by my friend, Professor Miller, of King's College. It has been known since the time of Gay Lussac that the precipitation of silver by chloride of sodium is interfered with by the presence of mercurial salts, and hence such a table is useful for reference in working the humid assay process:—

EFFECTS OF MERCURY ON THE PRECIPITATION AND DARKENING OF CHLORIDE OF SILVER.

Number of parts of mercury to 925 parts of silver.	Appearance of solution after precipitation.	Effect of light on the chloride for one hour.	Effect of light on the chloride for twenty-four hours.
·0	Clear.	Quite purple.	Dark purple.
1·0	do.	Purplish.	do.
2·0	do.	do.	Much coloured.
3·0	Faintly turbid.	Nearly white.	Shade of purple.
4·0	Slightly turbid.	Dead white.	Nearly white.
5·0	More turbid.	do.	do.
10·0	Very turbid.	do.	Dead white.

In my last paper mention was made of a nitrate bath measuring a little short of one pint, which had been thrown out of order by dipping plates coated with iodised collodion previously decolourised by mercury. Those of your readers who are in the habit of economising their waste solutions may perhaps inquire to what purpose this spoiled bath was eventually applied. The following process is the one which I have lately employed for converting old baths into solutions for printing. It is taken from a paper by Mr. F. G. Eliot, in the fifth volume of the Photographic Society's Journal, and proved quite successful in this instance, although I am not prepared to say whether the microscropic quantity of mercury supposed to be present in the bath was removed.

Make a solution of citric acid, containing sixteen grains in an ounce of water, and drop it into the spoilt bath in the proportion of a fluid drachm to each eight ounces by measure. If acetate be present in the bath the addition of the citric acid will produce a white precipitate, but in presence of free nitric acid the solution remains clear; the subsequent steps are the same in either case. Next immerse a strip of blue litmus paper, which will immediately be reddened; then add liquor ammoniæ drop by drop, until, after vigorous stirring, the blue colour of the reddened paper appears permanently restored. Now throw the whole on a paper filter, and when the liquid has run through, drop in an excess of pure nitric acid, sufficient to redden the test paper decidedly. Lastly, raise the strength of the bath to the proper point by adding thirty grains of nitrate of silver to each ounce.

No exact directions can be given as to the quantities of ammonia and nitric acid, but with the strongest liquor ammoniæ obtainable about two drops will be required for each drachm of the citric acid solution. The number of drops of the nitric acid must be varied according to the amount of the excess of ammonia.

The rationale of the process is as follows:—The citric acid, either with or without the aid of the ammonia, precipitates white citrate of silver in the bath, and this insoluble substance carries down the iodide of silver, previously dissolved in the nitrate of silver, and which, if allowed to remain, would interfere with the rapidity of the toning process. Excess of citric acid must not be permitted to remain in the bath, since it causes redness of the prints. Excess of ammonia, on the other hand, favours discolouration of the bath by use, and lessens the keeping qualities of the paper in hot weather, so that a trace of nitric acid is required to neutralise the alkali.

ON TAKING INTERIORS.

By Russell Sedgfield.

After all that has been said in favour of dry or sticky plates, it can hardly be questioned that wet collodion has great advantages where it can possibly be used, and I have been very desirous to apply it to taking interiors. The long exposure which such subjects require is a great difficulty in the way. The partial drying of the plate, and the concentration of the nitrate silver left on the surface, tend to produce stains which it is difficult to avoid in conducting the process in the ordinary manner. I have been trying lately to remedy this defect, and I think not entirely without success. The following variation in the usual method of preparing the plates is worth a more extended trial than I have been able to give it.

A bath is prepared in the usual way, but containing only ten or twelve grains of nitrate of silver to the ounce, and nearly saturated with acetate. I do not find it answer to make it much weaker. The plate, on removal from the usual bath, is immediately placed in this for a few minutes. If convenient it may be left for some time without injury. The rest of the process is conducted just as usual, using a pretty strong solution of pyrogallic acid, two or three grains to the ounce. If a plate so prepared is tried on a landscape, and developed almost immediately, it will be found less sensitive; but when the exposure is prolonged to ten or fifteen minutes, the difference in this respect between it and one prepared in one bath only will be found very slight, if anything; the risk of stains is much reduced, and a longer exposure may be given than could otherwise be ventured on.

The collodion for interiors should be rather thick, neither tough nor powdery, but something between the two—that is, spongy, so as to retain moisture for a longer time. I am not in the habit of making my own collodion, but endeavour to obtain this condition by the addition of more cotton and alcohol to what I purchase. It need hardly be remarked that for interiors a newly-mixed collodion is best, if potassium be used. If, however, cadmium is the iodiser, this is of less consequence, and perhaps for such subjects it has advantages. I generally use a mixture of the two.

Methylic collodion seems to be coming much into use. Some of our first makers have adopted it, judging by the smell. I rather doubt whether it is quite an innocent article. I have used it a good deal lately, and fancy that it gradually throws the bath out of order. The extreme heat of the weather may, however, have had something to do with this apparent effect. At any rate its cheapness entitles it to a full trial, and I shall be glad to learn the experience of others on the point.

I enclose a few specimens of the results of a two bath process for interiors.

[The stereographs sent exhibit the value of the suggestion made. They are far too good for a hasty review, and shall be noticed in detail in our next.—Ed.]

NOTICES OF RECENTLY PUBLISHED STEREOGRAPHS.

There are perhaps few persons who have not at one time or another experienced the delights of coming suddenly upon some well-remembered spot from which they have been long separated: the floodgates of memory are then opened, and a rush of mingled sensations is felt—of pleasure mixed with pain—in which the former, like good wine, is improved; and the latter, like its crudities, toned down by time. When these "green spots in memory's waste" are really beautiful in themselves, and not only so from associations connected therewith, of course the pleasure is materially heightened.

We experience these same joys to some extent (we may say to a considerable extent, and with the power of more or less renewing them at will) if we possess ourselves of well-executed stereographs of our favourite localities:—those where we have perchance wandered with some beloved one; where generous thoughts and noble aspirations have dawned upon us; where we have drank in renewed health from the life-giving air after a lingering attack of sickness, or where we have found rest and recreation for the over-tasked brain.

Again, how pleasant it is if we have not been able personally to enjoy our wonted trip, to see the spots that have delighted our dearest friend, our *fidus Achates*, and thus better comprehend the enthusiasm with which he speaks of that romantic mountain side, with the stream in the hollow, where he had the happiness of aiding the footsteps of the "lovely girl with the flashing eyes and slender ancles," none the less brilliant or the less lovely from the stimulus of our friend's presence no doubt.

It is such subjects as these, of which we have been *Dreaming in Print*, to which the series of views of Dovedale, in Derbyshire, recently published by Mr. Woodward, of Nottingham, belong. How different are they to the host of "got up" scenery trash, with its mock sentimentality, that acts almost as an emetic upon the beholder.

Apart from their stereoscopic value, the productions of Mr. Woodward have an intrinsic one of their own as faithful and pleasing transcripts of very charming scenery. Before noticing them in detail we may remark that the negatives are produced by the collodio-albumen process and executed with Mr. Woodward's well-known skill. In one or two the truthfulness of effect may be a little marred by slight over-development; not so the charm, however, for where this is the case the appearance of hoar frost on the ground is given, and that so naturally, that although we knew the cause *might* be what we have stated, we were so convinced that it arose from the frost being actually there in nature that we were only undeceived on reference to Mr. Woodward himself. When we mention that the negatives were taken "on a May-day morning early," when a portion only of the trees had put forth their leaves, the very natural appearance of this "pride" of the morning will be readily acknowledged; and lest our mention of it may be misunderstood as unnecessary faultfinding, we may observe that it is only apparent on two or at most three of the series, and that we scarcely regard it as a fault at all in the instances quoted.

In No. 74, *The Street Rock*, and 75, *Entrance to the Dale*, the frosted effect is noticeable in the former on the large dock leaves at the left-hand corner, and in the latter on the pathway amongst the grass, and on a picturesque rock standing out of the cool transparent water of the stream. Both are very pleasing subjects. No. 76, *Pickerill Torr*, is valuable as a geological illustration; as is also No. 77, *The Needle Rocks*—the latter being a particularly pleasing subject, and admirably executed. The brambles and other brushwood, with the velvety turf, form a fine contrast to the ruggedness of the gigantic rocks.

Of the entire series, however, No. 78 is our especial favourite. It represents the singular rocks called *The Twelve Apostles*, and is not only highly picturesque, but the execution leaves nothing to be desired. The graceful curve of the stream, the liquid effect of the water, the crispness of the foliage, and the remarkable contour of the weather-beaten rocks, rudely resembling human figures reclining against a bank—a resemblance heightened in one case by a small bush on the apex of the rounded mass of stone, presenting the appearance of curling hair—causes this slide to be peculiarly interesting.

In No. 79, the rock called *Dovedale Church*, the foreground is occupied by the stream, which reflects too much of the white light from the sky to be pleasant, and is, to our thinking, the least satisfactory by far of the whole. No. 80, *The View from the Lover's Leap*, completes a series with which all admirers of nature, where grandeur and softness contend for mastery, cannot fail to be enchanted.

AN ATTEMPT AT IMPROVEMENTS ON THE OLD ALBUMEN NEGATIVE PROCESSES.

By C. J. Burnett.

To be employed on glass or on waxed-paper, or on paper prepared with paraffine or solutions of paraffine, gutta-percha, gum dammar, copal, gum lac, amber, or other resin or allied substance in solution in alcohol, benzole, benzine, turpentine, camphene, or other solvent.

1. Prepare the salted albumen solution as usual* (or with addition of a chloride), but adding to it *further*, and in *addition* to the usual salt, common phosphate of soda (equivalent 358), or dipyrophosphate (equivalent, in crystals, 224), this addition being made in the proportion of one, two, or more equivalents for every equivalent of iodide which has been added.
2. Coat your glass plate or prepared paper by pouring on the albumen, or by floating alone on it, and then let it dry.
3. Sensitise with ordinary silver nitrate bath or with a rather weaker one, neutral or slightly acidulated.
4. Wash, dry, and keep in the dark as usual.
5. Expose in camera (or use for positive printing).
6. Develop as usual.

Further Remarks.—We may substitute for the phosphates *wholly* or *partially*, one of the organic salts, as oxalate of ammonia, or of potash (eq. 142 and 184), succinate of soda (eq. 136), Rochelle salt (eq. 121); and the following salts may also be named:—ferrocyanide of potassium, ferridcyanide of potassium, nitroprusside of sodium or potassium, cobalticyanide† of potassium, iodate and bromate, and periodate of soda, also cyanide of potassium. Much may not improbably be gained with regard to foliage, &c., from the ferrocyanides and some of its allies (in connexion with which see Mr. Hunt's *Researches*, page 129, &c.), using them either in the albumen as a substitute for part of one of the other classes of salts, or as a wash after sensitising.

Albumen has a great advantage over collodion in the variety of salts which are soluble in it, rendering it seldom necessary to have recourse to trimethylamene or other rare alkalies.

MR. KIBBLE'S INSTANTANEOUS PICTURES BY A DRY PROCESS.

By William Church, Jun.

These Pictures, which excited so much interest and speculation at Manchester, in Edinburgh, and here, prove to have been the exceptional results of numberless experiments from which Mr. Kibble has unhappily been obliged to desist from the state of his health. He has hitherto withheld any publication of his process from the commendable desire of being able to announce it with some certainty, but as he is now prevented from continuing his investigations he is unwilling that the germs of a method of obtaining such pictures as his *Empress Steamer*, taken on a dry plate in the fortieth part of a second, should remain unknown. I have, therefore, his authority for stating that the picture referred to and the greater number of his other "instantaneous" pictures were taken while experimenting with the arsenious salts of silver, and more especially while employing the arsenite. His results were, however, attended with too much uncertainty, and his experiments have been too incomplete, to admit of his stating how far the arsenious salts contributed to the sensitiveness of his prepared plates.

The process he employed was essentially that of Taupenot, and any deviations from its original simplicity have consisted mainly in the use of very thin collodion, containing arsenite of soda, and in the use of arsenite of soda along with a chloride in the albumen.

Mr. Kibble is disposed to attach a real value to his introduction of the arsenite of silver in the sensitive film, but I believe, and in this Mr. K. is inclined to agree with me, that his instantaneous pictures have been secured in the main by the substitution, so to speak, of development for exposure.

All these wonderful pictures of Mr. Kibble's were subjected to a very prolonged development, extending in some cases to ninety consecutive hours, and as some of them which contain trees, mountains, sea, and clouds, all perfectly delineated, are not indebted to any arsenical speciality in the collodio-albumen, the result must be attributed chiefly to the prolonged development. I may add, that the development was effected with a saturated solution of gallic acid in the usual way, the plate being supported, face downwards, and the solution and the containing glass dish being changed at intervals of an hour and a-half.

* Or with larger quantity of bromide.
† Also cuprocyanide and chromiocyanide.

THE BEST IODISER FOR COLLODION.

In looking over last year's volume of your Journal, I find at page 290, a letter from "Photo," on microscopic investigations of collodion. He there opposes the general opinion that Ponting's collodion is iodised with cadmium. In this he is partly right and partly wrong. Ponting's collodion is iodised with cadmium and calcium, the cadmium preponderating so as to produce a colourless collodion. Calcium, when kept separately, will often liquify and change to the colour of tincture of iodine, but in combination with collodion it is more stable than either iodide of potassium or iodide of ammonium.

A colourless collodion may look well and please many, but it is not necessary. A better iodiser than Ponting's is made with equal parts of the cadmium and calcium salts. The experience of three years with this iodiser has confirmed a professional photographer of my acquaintance in the opinion that it is the best he has ever used. Those who like ammonia can employ it in combination with the other iodides, in the proportion of ten grains of ammonium to twenty of calcium and thirty of cadmium. This is an admirable iodiser. For the collodio-albumen and Fothergill processes it would appear that cadmium is not the best iodiser, while it is universally admitted that iodide of ammonium is preferable with albumen. For use with those processes I should therefore reverse the proportions last given, and iodise with thirty grains ammonium to twenty of calcium and ten of cadmium. The last-named salt will prevent the liberation of free iodine in quantity sufficient to impair sensitiveness.

The objection to iodide of potassium is that it is impossible to procure it pure, and so long as this is the case it should not be used, as it is not absolutely soluble in collodion. It is a mistake to suppose this salt more sensitive than the others, the difference between them being scarcely appreciable, though cadmium must take precedence, both in point of sensitiveness and intensity. Cadmium has the merit of being the most stable of iodisers, and calcium ranks next, so that one cannot be wrong in using these salts in the proportions I have mentioned.

When bromides are to be used with negative collodion, it may be as well to iodise partly with ammonium, and in this case there should be three grains of iodide to one of bromide. The following will be found to work well:—

3 grains iodide and 1 bromide of ammonium	24 grains.
6 grains iodide and 2 bromide of calcium	
9 grains iodide and 3 bromide of cadmium	

This quantity will bromo-iodise six ounces of collodion.

I will only add that one of our most successful operators, the Rev. Mr. Cleaver, iodises his collodion as follows:—

Iodide of cadmium	15 grains	One ounce of this to four ounces of plain collodion.
Iodide of calcium	10 "	
Iodide of ammonium	15 "	
Bromide of ammonium	20 "	
Alcohol	3 ounces	

That is to say, he uses one-third bromide and two-thirds iodide, or rather too much of the former. The proportions I recommend are safer for general work, though of course the changes can be rung upon them *ad libitum.* But the merit of his iodiser is that it contains cadmium and calcium, and without these salts I believe no collodion can be deemed first-rate. R.

PERMANENT POSITIVES.

By M. Lafon de Carmasac.

In the early part of the year 1855, in a memoir presented to the Academy of Sciences, at its meeting of June 11th, I described certain processes by which I produce photographic pictures with various materials.

The colouring materials selected at the will of the operator are actually substituted for the photogenic agent, and fixed upon glass, porcelain, enamel, metals, ivory, paper, wood, &c. Some proofs, formed of the oxides of copper, iron, manganese, cobalt, gold, and silver, fixed on glass and enamel by fusion or by the muffle, offer the best guarantee of permanence, with great splendour and variety of colour. Having for many years sought the solution of the problem of fixing the photographic image, I investigated at this period its most difficult and most conclusive phases, and at once succeeded in producing images incrusted by fire in ceremaic materials, the permanence of which is indefinite. Although many interesting applications presented themselves to me at this time, I devoted all my efforts to improving the character of the optical image, to the simplification of the manipulations, and to the solution of the problem of curved and accidental surfaces of the supporting substances, to numerous experiments upon colouring materials, with reference to their durability, and the mode of fixing. These improvements ought to precede every attempt to apply them to the arts and manufactures.

Substances which support the picture: Colouring agents—Porcelain, enamel, earthenware. The picture is formed of metallic oxides, and fixed in the muffle.

Chinaware, biscuit, hard enamel, glass, crystal. Fluxes are added to the metallic oxides, and fixed in the muffle.

If the biscuit is to receive a glaze, cobalt is used, and fixed in the furnace.

Upon various white or deeply tinted materials I also form the image in gold or silver with their fluxes, and fix in the muffle. The metal may be kept *mat* or burnished.

Silver — The image is produced in gold, or in a combination of silver and lead employed in niello, and fixed in the furnace.

On paper, parchment, gelatine, ivory, wood, prepared linen, &c., the image is formed with various colouring materials, and fixed with gum, albumen, glues, oil, varnish, or encaustic.

On the various deeply-coloured materials, the image is also made in silver, gold, and bronze.

Colouring with vitrifiable pigments commands the whole palette of enamel painting. Colouring on papers may be varied to infinity. In either case, with reference to finish and homogeneous aspect, there is no objection to forming the image with mixed colouring materials, having regard, of course, to the laws which govern their combination in fusion.

All the pictures I have described can be produced by the pencil. They can also, within certain limits, be obtained *photographically* with the various colours, which is of importance in the final colouring of the proofs; for the artist will not have to contend with the monotony of the ground-colour, but finds to hand a sketch coloured in harmony with the result he desires to attain. He will therefore be able to obtain brilliancy and richness of tone, without compromising the integrity of the picture obtained by the action of light, by employing opaque pigments. Whatever be the substance upon which we desire to obtain a picture, we can always produce this image with permanent materials. We can avail ourselves of the effects of frosted and burnished silver and gold, and colours, according to the result desired. These results are obtained upon objects of every shape. The photographic problem would, therefore, appear to be completely solved.

By vitrifiable materials or associations of metals, by furnishing a beautiful ornamentation to the vitreous and ceremaic arts, and to the goldsmith and jeweller, and many other arts.

By ivory, wood, prepared linen, &c., by substituting beautiful designs for the crude pictures so generally employed in the arts which employ costly woods, ivory, shell, &c., and minister to the daily wants of life.

By paper, with the image in carbon or any other unchangeable material, in permitting museums to be enriched with precious materials, and rendering collections of all kinds possible; galleries of portraits, representations of remarkable events, important historical documents, rare book illustrations, the diffusion of everything graphic that can interest the public—analogous to printing and engraving.

By the combination of all these means, in greatly extending the artist's field of operations, by creating the photographic product. In colours there are effects of all kinds to appropriate, he can combine general ornamentation with form, &c. Besides the permanent materials he makes use of, permit him to make a valuable work; the operator need no longer draw back from artistic studies which aim at the beautiful, since this beauty he will be able to appreciate in a durable manner.

These suggestive processes, described in 1855, appear to me to have suggested carbon printing and other novel processes. They have received, since that date, various improvements in my hands. The principle, however, remains the same, and will, I think, remain unchanged.

The images I have produced are so perfect that I can multiply a negative upon glass or waxed-paper, with all the vigour and finish of the originals.—*Cosmos.*

PHILOSOPHY OF POSITIVE PRINTING.

MM. Davanne and Girard, in continuing their researches upon "fixing," have noted some facts which they announce briefly in anticipation of their report, and to which we made allusion in a former number. The following is condensed from *Le Bulletin*, &c.—

Every photographer must have observed a curious phenomenon

that exhibits itself when positive proofs are immersed in the fixing solution upon being taken out of the printing frames. The proof quickly loses its violet hue and acquires a red colour, which varies under different circumstances, but which is constantly produced. Hitherto this phenomenon has been explained by saying that the sub-chloride of silver in the proof is decomposed; but as the theory of the sub-chloride is rejected by MM. Davanne and Girard, they see the necessity for assigning the phenomenon to some other cause.

Remembering that in the course of their researches they had constantly seen this red colour arise from a combination between the reduced nitrate of silver and the "sizing," they thought that the explanation of the phenomenon was to be looked for there. Reflecting also upon the nature of the fixing agents employed—ammonia, hyposulphite of soda, cyanide, &c., they remarked that all these substances have an alkaline reaction. Now it is well known that the alkalies have the property of making the substances employed as sizing *swell-up*, that is, of bringing them to a sort of imperfect solution; and this is especially the case with starch. Therefore it appeared quite rational to suppose that at the moment of immersing the proof in the fixing solution, the latter exercises its alkaline re-action upon the "sizing," causing it to swell, that is, making it begin to dissolve, and consequently render it apt to combine with the reduced nitrate of silver, which it could not do previously, because these substances were all in the solid state.

If this hypothesis be correct it is easy to verify it. In the steam of boiling water we have an agent which, incapable of effecting chemical decomposition upon the salts present, can yet exercise the same "swelling" action as an alkali. When, upon taking it from the printing frame, we expose a proof on paper sized with starch to the vapour of boiling water, it immediately assumes the familiar red hue which it acquires in a solution of hyposulphite of soda; but plunged in cold water, the same proof undergoes no evident change, for cold water does not cause starch to swell much.

Experience has confirmed the truth of these facts. A proof upon paper sized with starch, immersed in cold water undergoes no change in hue, but it immediately becomes red when immersed in boiling water or exposed to its steam.

The question arises—is this the sole cause of the change, or is the phenomenon complicated with accessory phenomena? This will be investigated and established by the authors in their forthcoming memoir. At present they content themselves with making known the preceding facts, which appear to have some importance in connection with a theory of fixing.

They are satisfied that all the salts having an alkaline reaction, such as phosphate of soda, borax, &c., act in the same manner as ordinary fixing agents, although more slowly.

PROPOSED CONTRIVANCE FOR KEEPING WAXED OR PLAIN PAPER PICTURES LONGER THAN USUAL BEFORE DEVELOPMENT.

By C. J. Burnett.

The necessity of developing within a very short time after the picture has been taken, has been long a very general complaint against the paper processes. Mr. Young's plan of hypo-fixing before development would remedy this; but there is also a much simpler and less objectionable plan which promises to answer well enough, being simply the washing away of the free nitrate from the paper. This can be done either at once, or quite well in the evening, when we come home, and the papers will then keep for at all events some days before development. The presence of nitrate or allied salt during development is, however, necessary, and may be secured either by developing in a bath containing nitrate of silver, along with acidulated gallic acid or sulphate of iron, or else by immersing the papers, with the dormant picture in it, first in a nitrate of silver bath (containing, it may be, a little acid), and then in a solution of gallic acid (with or without acetic or citric acid), or in a solution of acidulated sulphate of iron.

To retain the oxide of silver in the print during development, and prevent its being dissolved out by the water in the gallic acid, or other development bath, any one of the three following plans may be resorted to:—

1. The mixture of phosphate of soda, or oxalate of potash, with the gallic acid bath; or of rochelle salt, or citrate of soda, with the iron bath, where it is used.

2. The dipping of the paper on which the latent picture is, first in one of these salts, and then in nitrate of silver, before immersing it in the developing bath; or

3. The reversing this so far, by making the nitrate of silver bath precede the bath of the phosphate, oxalate, or similar salt, concluding with the gallic or ferrous development bath as usual.

ON STRENGTHENING NEGATIVES.

By Dr. Henry Draper, New York.

Collodion negatives may be readily strengthened by the application of a solution of protochloride of palladium, which is easily prepared by dissolving small pieces of this metal in *aqua regia*, which acts upon it very promptly, and produces a solution the colour of which is a dark brown-red. It must be evaporated to dryness, taking care that the heat be not so high as to decompose the chloride, but yet sufficiently prolonged to disengage all the acid. The brown residue, which is protochloride of platinum, is soluble in water, and in this state is employed in photography.

If we take a collodion negative which has been fixed with cyanide of potassium or hyposulphite of soda, and still moist, and pour over it a given quantity of this solution, a change will be immediately apparent: the proof gradually becomes darker. In those portions which have most intensity a deep velvety black is obtained, impermeable to light. Whether the picture be negative or positive the effect is the same, although it will be less in the latter than in the former, and the intensity is equally the same both by reflection and transmission. In the application of the protochloride, if the solution be strong, the effect takes place almost immediately. A prolonged exposure is useless and produces no new result. The solution will serve again and again until exhausted. As it becomes weaker its action becomes slower, and the operator will take the precaution to examine the glass on both sides, to ascertain if the film is thoroughly penetrated. The most favourable time for applying the palladium is immediately after fixing; but it may be employed at any subsequent period, if the film be previously moistened with water, but the result is less satisfactory. There is no difficulty in employing the protochloride nor any fear that it will produce stains on the glass. As a proof of the advantages to be derived from the use of this agent, it may be stated that a collodioned plate, prepared in the usual manner, was exposed to the light of an Argand lamp at a distance of four inches; and a fourth of an inch uncovered at successive intervals of four minutes, two minutes, one minute, ten seconds, and five seconds; the effects thus produced on the collodion film by the light of the lamp were then developed in the usual manner, and the half of each strengthened by chloride of palladium, leaving the other half intact. Upon taking a print from this negative, it was observed that the part blackened by the chloride, which had been exposed five seconds to the light of the lamp, was as intense as the portion which had been exposed eighty seconds, but not strengthened with the chloride. It may therefore be concluded that the opacity of the negatives is augmented sixteen times by the employment of protochloride of palladium.

It also exercises a good effect upon the collodion film by rendering it more adherent, so that the image thus treated will be more resistent than others.

DEVONSHIRE CUSTOM.

The other day an old friend, to whom we had lent some stereographs, produced by Mr. Widger, of Torquay, himself a skilful photographer, and a native of Devonshire, favoured us with the following interesting piece of gossip:—

"The Photograph marked *Tor Abbey*, which is a portion of the old building that has been converted into a barn, brings to my recollection a custom which formerly prevailed in that neighbourhood, but which may now be considered obsolete, for I do not think that it has been practised for more than half a century.

"In my childhood many of the farmers used to give a supper to their work-people and servants on Twelfth Eve; and that it was an ancient custom may fairly be inferred from the fact that in some houses it was kept on *old* Twelfth Eve.

"The ostensible purpose of the gathering was to ensure a good bearing of apples the next autumn by *firing at the trees*.

"An account of the ceremony has been published; but as it differs in many respects from what was practised within my memory, I will describe it as an eye-witness.

"The supper was a plain but substantial one, and a cake was made having the same qualities—very unlike those that are exhibited by the London pastry-cooks on Twelfth Day. The drink, of course, was cider, finishing off with a large jug of "cider and——" that is to say, cider and brandy; the cider being heated with ginger and sugar, and a fair proportion (about one fourth) of brandy being added to it. This was by no means a bad drink on a cold winter's night on returning from the out-door ceremony.

"In the course of the evening, generally after supper, the party proceeded to the orchard, all the guns that could be procured being

loaded with powder for the occasion. There, in front of some favourite tree, the following address was spoken, or rather *shouted*, with the united force of all the assembled lungs:—

Here's to thee Old apple tree,
Beer and blow, Apples enow.
Hats full, caps full, bushell—bushell bags full,
And Tor Abbey great barn full.
Hurrah! Hurrah!

Bang!—bang!—the firing being the climax.

"This was repeated at different parts of the orchard; and the party then returned to the house quite prepared to do justice to the good cheer within.

"On one of these occasions my father happened to be from home, and his fowling-piece was taken by some one unaccustomed to shooting, who, loading in haste, forgot to withdraw the ramrod, which, of course, was shot away and never afterwards found.

"This, I believe, was the cause of the custom being discontinued in *our* house. I know that it was left off long before I was old enough to handle a gun; so that the only part I ever took in the proceeding was to add my feeble voice to the shout.

"That the ceremony was at one time really supposed to promote its ostensible object is highly probable, for we cannot otherwise account for its origin; and I have myself heard it remarked, when some usually prolific trees have failed to bear, 'we forgot to fire at them last Christmas.'"

It may be asked—"What has this to do with photography?" if so, it must surely be by the unimaginative being described by Wordsworth, when he says—

"A primrose by the river's brim
A yellow primrose was to him,
And it was *nothing more*."

What but a photograph, or the actual scene itself, could have roused from the treasures of memory so vivid an impression of scenes in which the actor took part more than half a century previously?

THE LATE FREDERICK SCOTT ARCHER.

It is doubtless known to most of our readers that the late Mr. Frederick Scott Archer, at his death, left a widow and young family unprovided for. Recognising the eminent services this gentleman had rendered to photography, it was thought that no better tribute could be paid to his memory than by raising a subscription for the benefit of his bereaved family, and protecting them from indigence. The effort was made, but the result was not so flattering to the liberality of the photographic profession as was hoped for.

Mr. Archer's widow followed him to the grave within a brief year after his decease, leaving three little children to the tender mercies of the world. Among the new pensioners on the Civil Service Pension List we find the names of Alice, Constance, and Janet Archer, as recipients of fifty pounds a year, held in trust by Nathaniel Maclean and Roger Fenton, Esqrs. This sum will save them from want, it is true, but alone it is a very small tribute to the services of one who has rendered such important aid to photography, and to whom every photographer is under the deepest obligation. We believe that Sir William J. Newton has been mainly instrumental in obtaining the grant, which is one that will be a very welcome addition to the Archer Fund, a fund still open for augmentation if any of our readers who have not yet contributed feel disposed to do so.

BLACKHEATH PHOTOGRAPHIC SOCIETY.

Nitrate of Uranium.—The conflicting claims of M. Niepce de St. Victor and Mr. Burnett to the honour of having introduced this substance as a photographic agent.

The following official reply to some editorial remarks of our own, and to a letter of Mr. Burnett, recently inserted in these pages, has been sent to us for publication:—

Blackheath, July 27, 1859.

Dear Sir,—In your number for 1st June you make a remark on our annual report which we regret has remained so long unnoticed. The cause of the delay has been our wish, before writing, to get a sight of Mr. Burnett's paper, in order that full justice might be done him.

The catalogue you so kindly sent us we cannot look upon as a publication in the true sense of the term, as, though affording good evidence to all into whose hands it came, its circulation was entirely confined to the comparatively few who visited the Glasgow exhibition of photographs in 1855. Having been expressly referred to a paper read before the British Association in that year, we naturally first consulted their printed reports, where no such paper is to be found; nor, as far as we can discover, is it mentioned in any of the journals which gave reports of the Glasgow meeting.

It now appears from Mr. Burnett's letter in your last number, that his paper was never published till 1857 in *Photographic Notes*, so we had been searching for it some two years too early. Having read his paper, we reply to your remark in the first place, that we had no intention of crediting M. Niępce with being the introducer of uranium as a photographic agent, when we spoke of his uranium printing process as one of some promise, any more than if we spoke of the negative process of A. B. we should mean that A. B. was the first who ever made a negative. We simply referred to his particular method of using it, detailed in his paper in the *Comptes Rendus* for March, 1858. We were certainly not aware at the time of the close identity of his process with that of Mr. Burnett's, published in 1857, or we should not have failed to notice it. At the time our report was written M. Niępce's prints were being handed about at various scientific societies in London, and excited great attention, not only on account of their beauty, but also because of the great stability which he ascribed to them. When speaking of M. Niępce's experiments, we naturally noticed them, and none can regret more than ourselves that in so doing we should have even appeared to do wrong to Mr. Burnett. A simple reference to where his results were to be found would have caused us long 'ere this to have recognised his claims.

To Mr. Burnett's coarse accusation of giving a certificate to a monstrous and systematic plagiarism, we can only reply that, in all probability, M. Niępce is as guiltless of the plagiarism as we are of endorsing it. Nothing is more common than for two men experimenting on the same subjects to arrive at similar results; and the extremely limited circulation of English periodicals on the Continent renders it very improbable that, at the time his paper was read, M. Niępce had even heard of Mr. Burnett's experiments.

Mr. Burnett will not find that the use of intemperate language will at all advance his claims to be considered an inventor.

JAMES GLAISHER, President,
On behalf of the Council of the Blackheath Photographic Society.

NOTES OF A PHOTOGRAPHIC TOUR IN THE HOLY LAND.

No. III.

IN THE VALLEY OF JEHOSHOPHAT.

This morning my eyes are gladdened and my heart is cheered by the sight of a bundle of letters and papers from home. Truly, manna in the wilderness, and I bless the good Samaritan who so promptly despatched a fleet messenger from Cairo, to track my wandering footsteps to the shores of Askelon, who halted and rested not until he placed the precious burden at my feet. To day I will hold jubilee. I will recline under my tent and read my letters, and con over the columns of The Photographic Journal, some half-dozen numbers of which form not the least interesting item in my packet.

"Ho! Hassan! Prince of the Faithless!
"Hassan is the slave of the Howajji.
"Bring Coffee!"

Tradition relates that Ramleh is the ancient Ramah. It stands on the borders of the great plain of Sharon. To the east are the mountains that separate it from Jerusalem, to the westward lies the sea. You may perceive the blue Mediterranean from the summit of the tower. We halted for the night at Ramleh, and in the early morning I took four views of the city and adjacent scenery. That done I struck across the plain to Ludd, a modern city on the site of the ancient Lydda, a distance of about four miles, while the sun was ascending from behind the hills of Ephraim.

The ruins of the ancient city are imposing, those of the vast church of St. George especially so. It was at this place that our national saint was born, and, for aught I remember to the contrary, it was here he fought and slew the dragon. The bishopric of St. George, at Lydda, was one of the most powerful sees in the Christian Church. It is celebrated in Scripture history as the scene of Peter's miracle of the healing of Eneas.

I had intended to proceed to Jerusalem from Ludd, but while seated meditating amid the ruins of the old church, I suddenly bethought me that I should miss seeing Jaffa, the Joppa of Scripture, and unless I now made a deviation from the route of some twelve or fifteen miles to go down to the coast, I might in all probability not see it at all. We had no inflexible route marked out, but desired to visit every place of interest, in connection with the main object of our journey. As for me, I cared nothing where I might lay my head on the morrow. Wherever it might be, I knew I should be sure to find material for the exercise of my photographic abilities.

The baggage mules were in the rear. We had but to leave an order for them to alter their course, and then start at a gallop

across the lower end of the plain of Sharon, when in about a couple of hours we reached the most luxurious groves of oranges and prickly pear, from among which we emerged suddenly at the gateway by which you enter the city of Joppa.

The aspect of Joppa is stately and commanding: the city stands upon a hill, or knoll, which forms a promontory on the sea coast. It is surrounded by a strong, gray, venerable-looking wall, which dates from the times of the Saracens. When you enter the gateway on the land-side you step at once into a crowded bazaar, and and then you find yourself in the filthiest of seaport towns, crowded with Arabs and fleas.

I took a stroll through the streets of the city, seeking what I might find, and devouring, as I walked, some splendid Jaffa oranges. Many groups and picturesque subjects for photographs presented themselves, which I would gladly have transferred to my portfolio, but I knew the attempt would be hopeless. Had I planted my camera in the streets of Joppa I should have been devoured by human flies. Outside the city I find more elbow-room: with our mules and horses I form a hollow square, within which I plant my camera in peace, without fear of being pounced upon by marauding or suspicious Bedouins.

The views I took of this picturesque city are among the most interesting I have yet obtained, perhaps even the most so. Joppa was a city of the Philistines, celebrated chiefly in ancient times as the port of Jerusalem, to which Solomon brought his timber from Tyre. Jonah sailed from this port when seeking to escape the duty assigned him; and it is not far hence that they show the identical place where the whale threw him out on the sand. At a subsequent date Joppa became a point of interest in Christian history. It was here that Peter performed the miracle of raising Dorcas to life; and here, also, he saw from the house top of Simon the tanner the sublime vision which declared that all distinctions between Jew and Gentile were for ever swept away.

They point out, in the heart of the city, the house of Simon, a little square stone building, with an open roof, looking out upon the sea:—the veritable house of the tanner, believe it who will. Half-naked Arab children lay on the sunny pavements of the court, both common and unclean in appearance, and an atmosphere of filth enveloping everything around. The streets were ancle deep with mud. Everything was melancholy, as everything always is in an Eastern city. I panted for the free air, and slowly and dejectedly walked out to the fresh shady spot where our tents were pitched.

The East is the Paradise of those who desire to indulge their self-importance. With what an air of grandeur you can order breakfast when you have an obsequious slave to wait upon you! It is impossible, amid the grandeur that surrounds you, with the hot red sun shedding his glory on the scene, to say, in homely phrase, "Bring breakfast." You feel that you must indulge in Oriental magniloquence and pompous phrase; therefore do I say, "Ho! Hassan, prince of the faithless, bring coffee!"

I thought this morning I would pay minute attention to Hassan while he busied himself in preparing the infusion of the fragrant berry. The operation of roasting the berries I did not see performed. My observations commenced with the grinding or pounding between two stones, one slightly hollowed for the purpose. The coffee-pot was of silver, with a tightly fitting cover, within which a ring fitted, to which a flannel bag containing the pounded coffee was suspended. Pouring boiling water upon this, it quickly filtered through, as clear as wine, and was immediately transferred hot and fragrant to the little cups on the board. I essayed to discover the philosophy that guided Hassan in his operations, and think it may be summed up in two words—*quick* and *hot*. He never made me more than one cupful at a time, for this reason, that the second would spoil while I was sipping the first; for here, coffee is not drank but sipped. If you wish to obtain the exhilarating, restorative effect of coffee, you must take it without milk; with this addition, however, it is more nutritive by virtue of the milk added, but less exhilarating. Happy Orientals, to whom chicory is unknown! When that foe to the fragrant berry insinuates its insidious presence on the desert, may the days of the adulterators be numbered! I heartily applaud the manner in which those who tamper with the purity of the necessaries of life are treated in these regions. And I must confess I should rejoice to see a fraudulent grocer nailed by the ears to his own doorpost in Whitechapel, a terror to all evil-doers.

"Woe unto the inhabitants of the sea-coast, the nation of the Cherethites! the word of the Lord is against you: O Canaan, the land of the Philistines, I will even destroy thee, that there shall be no inhabitant!"

All the terrible denunciations of Scripture rushed into my memory as I walked through the narrow, vile, and filthy lanes of the cities of the Philistines. With every facility for a prosperous commerce, the trade is limited to dealings with the Egyptian and Damascus caravans. Some shops for the peddling of smallwares alone represent the commercial importance of a city once a proud mart of Mediterranean commerce. I cannot impart to you the emotion and enthusiasm I experience as I tread this sacred soil: its rocks, trees, and flowers remain, but the men who dwelt among them have given up the ghost, and where are they? D. T.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER IV.

MAXIMS, &c.*

FAILURES more frequently arise from the want of a proper foundation than any other cause. Let not the student of these chapters therefore consider such preparatory pages tedious. There is no royal road to art, and impatience is not favourable to progress, as witness the old adage, "The more haste the less speed," and another famous saying, about "Slow but sure." It is a true sign of quackery when the difficulties of any art or science are overlooked or ignored, and quackery is but the voice of ignorance. Speaking from my own experience, I say emphatically that *the thoughtful head best aids the industrious hand.* In the earlier stages of my progress I trusted to the latter almost entirely, and was reduced very frequently to despair; but when I combined the two, then real progress was made, and I have been sanguine and progressive ever since, earnestly hoping to remain so to the end, for "art is long and life is short," and the goal of perfection has not yet been reached in any branch of this world's knowledge. The true artist is always a student, and he who has acquired most is ever the most conscious of his deficiences. The great Titian, when he had studied and painted until he was seventy years of age, *then* only *began* the best part of his career; but on his deathbed, far, far away, there still loomed before his outstretching love the goal he had been so long nearing, still misty and faint in the extreme distance as it had ever been, and ever would remain! When you think of this, can you hope to master, at once, one of the most important branches of an art which baffled for years the powers of the mightiest of its great masters?

I shall now proceed to arrange a set of maxims founded upon the experience of some of our most successful painters.

The following maxims, given under the proper headings, will illustrate the principles and practice of colouring, and form one of the best introductions to brushes and colours that I could select. I might have embodied most of the ideas in my own words; but by so doing, I should have deprived these maxims of the weight they derive from the great names attached to nearly all of them as quotations. Each maxim is numbered, in order that we may easily refer to any hereafter, to illustrate and explain more mechanical directions.

GENERAL MAXIMS.

1. "Outline and chiaroscuro may make a finished drawing, but it is an imperfect substitute for the totality of painting, which comprehends the whole natural appearance."—*Barry.*

2. "Scientific rules are the only sure and easy, though deliberate, conductors of true genius."—*C. Hayter.*

3. "GENIUS, with the *utmost aid of scientific theory,* must submit to *practical application,* as rudimentally necessary to accomplishment in the practical and mechanical department of *painting.*"—*Ibid.*

4. "Genius cannot supply the want of competent knowledge."—*Ibid.*

5. "Art, by practice, to perfection soars."—*Fresnoy.*

6. "Acquire a certainty of hand by deliberate attention to the natural but most characteristic properties of each *individual* object: this will prevent that sort of conclusion which is the parent of 'MANNER.'"—*C. Hayter.*

7. "Take care to use your materials so that the picture may not look *painty.*"—*Ibid.* "There is a degree of impiety in pleading a want of faculties, when the real want is proper industry and method to make right use of them."—*Ibid.*

MAXIMS FOR COLOURING GENERALLY.

8. "Inasmuch as a gamut is not any distinct tune of itself, so a chromatic display of the formation of colours is not any distinguish-

* In making use of some of the best maxims of artists who have written books, I must solicit the indulgence of their authors or publishers, and trust, that in giving my pupils such extracts I best serve the purpose these works were written to aid, viz., the advancement of "*true art.*"

able picture; yet so perfectly do each develope that systematical order by which nature has determined harmony, that, without them, painting with regard to colours, as well as music with regard to sounds, would remain to all, as they still do to all those who are unacquainted with them."—*Ibid.*

9. "The predominant colours of the picture ought to be of a warm, mellow kind, red or yellow; and no more cold colour should be introduced than will be just enough to serve as a ground, or foil, to set off and give value to the mellow colours, and should never of itself be principal."—*Sir J. Reynolds.*

10. "The fewer the colours the cleaner will be their effect."—*Ibid.*

11. "*Two* colours mixed together will not preserve the brightness of either of them *single*, nor will *three* be as bright as *two*; of this observation, simple as it is, an artist who wishes to colour bright will know the value."—*Ibid.*

12. "I am confident that an habitual examination of the works of those painters who have excelled in harmony will, by degrees, give a correctness of eye that will revolt at discordant colours, as a musician's ear revolts at discordant sounds."—*Ibid.*

13. "Every hue throughout your work is altered by every touch that you add in other places, so that what was warm a minute ago becomes cold (by contrast) when you have put a hotter in another place, and what was in harmony when you left it becomes discordant as you set other colours beside it; so that every touch must be laid, not with a view to its effect at the time, but with a view to its effect in futurity."—*Ruskin.*

14. "Fine colouring consists of truth, harmony, and transparency of tints."—*Opie.*

15. "The true colourist first considers the nature of his subject, if grave, gay, magnificent, or melancholy, heroic or common."*—*Ibid.*

16. "Colour must be employed to harmonise, vigorate, soften, and aid chiaroscuro, giving breadth and unity to the masses of brightness or obscurity, and in distinguishing by their depth, strength, or brilliancy, the principal or subordinate figures."—*Ibid.*

17. "Good colourists break up the appearance of predominating masses of colour by a repetition of similar tints."—*Ibid.*

18. "Transparency is not flimsiness, brilliancy not rawness."—*Ibid.*

19. "Flesh is not roses, nor vulgarity vigour; character and truth are lost in the hues of flattery."—*Fuseli.*

20. "Colours, as in a prism, should emerge from and flow into each other."—*Ibid.*

21. "If the principal colours in a picture consist of green, blue, or red, all the other parts ought to possess small portions of the same to unite the whole."—*Gerard de Lairesse.*

22. "The hand that colours well must colour bright,
Hope not that praise to gain by sickly white."—*Fresnoy.*

23. "Reflecting surfaces tincture the objects reflected on with their colour, proportionately with their distance from each other, the angle under which the light operates, and the textures of both surfaces."—*C. Hayter.*

24. "The general prevailing colour of light tinctures every object within its influence: for instance, observe the whole hemisphere at clear mid-day, or the time of a warm sun-setting, or the grey effects of a cloudy sky, or a fog."—*Ibid.* [This rule should be remembered when painting any peculiar effect of light on the figure or background. It is no uncommon thing to observe the gloom of a storm in the background when the figure is as brilliantly lighted as if in the full blaze of a summer sun; or the hues of *sunset* about the horizon, behind a figure lighted by rays from the sun at noon, &c.

25. "When a white surface *reflects* on the *shadowy* part of any colour, it looks *paler* than the *lighted* parts of such colour; but the power of the shadow holds it inferior with regard to light."—*Ibid.*

26. Glossy surfaces reflect the colour of the air or surrounding surfaces; and, for this reason, what is called the true "local colour," is not seen upon such surfaces where they receive the light, but rather in the half-tones; objects less polished or smooth best exhibit local colours.

27. "Every colour that is reflected on by its own colour is enriched thereby, according to the strength of the reflected light." —*C. Hayter.*

28. "Every colour that is reflected on by its directly opposite colour will be neutralised thereby; such as *green* against *red*, *blue* against *orange*, or *purple* against *yellow*, in an equivalent degree with the power of light."—*Ibid.*

29. "If any two approximate colours reflect the one on the other, its tincture will approach the appearance of that compound which the two other colours would make by mixing them."—*Ibid.*

* How often do the accessories quarrel with the principal object! Jones, a journeyman tailor, looking a journeyman tailor, with the background of a palace, provokes sarcasm and ridicule; but the same subject, with a quietly characterised background, &c., is quite another thing.

30. *The deepest shadows are not quite black;* for although the presence of shade indicates in its degree the absence of light, and consequently of colour, still it is very seldom indeed that they are not redeemed from positive blackness by the presence of reflected light.

31. *The mere imitation of colours is not sufficient to produce really natural effects*, because, as our highest or most brilliant light, white paint, falls far short of the brightness of white light, so our *black* is as far removed from the intensity of nature's darkest shadows: hence it is that certain painters guilty of "*exaggerated colouring*" have yet conveyed to every spectator an impression of *truthfulness*; and others who have laboured to reproduce *with their poor scale of coloured pigments* the very tones, tints, and shades of their model, have failed to satisfy either themselves or their patrons. Howard says—"As it is impossible with pigments to rival the brightness of light, it is found necessary to adopt some method of forcing the effect of colours, so as to conceal or supply a compensation for this deficiency, and *apparently* to produce the vigour of truth."

32. "Let no one think the force of colouring consists in the choice of beautiful colours alone, as fine whites, beautiful azures, green, or the like, for these are equally beautiful before they are made use of; but in knowing how to manage them properly."—*Ludovico Dolce.*

33. "We are to consider in what part any colour will show itself in its most perfect purity; * * * different colours differ materially in this respect. Black is the most beautiful in its shades; white in its strongest light; blue and green in the half-tint; yellow and red in the principal light; gold in the reflexes; and lake in the half-tint."—*Leonardo da Vinci.*

34. "When you want to know if your picture be like the object you mean to represent, have a flat looking-glass, and place it so as to reflect the object you have imitated, and compare the original with the copy."—*Ibid.*

35. "One painter ought not to imitate the manner of any other; because in that case he cannot be called the child of nature, but the grandchild."—*Ibid.*

"Whoever flatters himself that he can retain in his memory all the effects of nature, is deceived, for our memory is not so capacious; therefore *consult nature for everything.*"*—*Ibid.*

36. "When the work is equal to the knowledge and judgment of the painter, it is a *bad sign;* and when it surpasses the judgment, it is still worse—as is the case with those who wonder at having succeeded so well. But when the judgment surpasses the work it is a *perfectly good sign.*"—*Ibid.*

37. "The edges, extremities, or boundaries of *all* shadows are *grey.*"—*Howard.*

38. "From the effect of contrast, shadows appear *comparatively* of the opposite colour to that of the light."†—*Ibid.*

MAXIMS FOR COLOURING FLESH, &c.

39. "The painter must always keep an attentive eye upon the *tints* and *softness* of flesh; for there are many who paint it so that it appears like porphyry, both in colour and hardness. * * * For my part, I would prefer browness to an improper white; and would, for the most part, banish from my pictures the vermilion cheeks and lips of coral, which make the faces look more like *masks* than *nature.*"—*Ludovico Dolce.*

40. "Paint your lights *white*, place next to it *yellow*, then *red*, using *dark red* as it passes into the shadow; then with a brush, dipped in cool grey, pass gently over the whole, till they are tempered and sweetened to the tone you wish."‡—*Rubens.*

41. "All the retiring parts of flesh partake more or less of grey." —*Mrs. Merrifield.*

42. "Strong shadows should be warm, those of flesh (which is semi-transparent) always incline to red."—*Ibid.*

43. "All the shadows of flesh must have grey edges. This prevents hardness and gives great richness."—*Ibid.*

44. "The reflected lights of flesh are warmer than the surrounding parts."—*Ibid.*

"The darkest parts of shadows are near their edge, the middle being lighted by reflected lights."—*Ibid.*

45. "The divisions or roots of the hair being shown prevents the appearance of a wig."—*F. Howard.*

The vivid spark of light in the eye falls upon the most prominent part, and diagonally opposite it will be found a reflected

* I have introduced this maxim, and some others, to tell against a practice commonly prevalent among photographic colourists, viz., that of painting from memory, aided only by a few brief written notes, rather than from the sitter.

† "Comparatively," because liable to certain modification from the effects of atmosphere, reflected colours, &c.

‡ These directions are intended for oil. The principle is *very good;* but in the works of this great master we find these colours placed side by side with so little attempt to blend them, that the effect is coarse and unnatural. The "cool grey" is of course not intended as a glaze to be carried at once over the whole of the flesh.

light, stronger or fainter, according to the prominency of the eye and position of the spark, which is, in the photograph, universally exaggerated. The eye's transparency and life-like expression will be obtained by carefully strengthening and studying the position of the spark and reflected light.

Remember that in nature there are *no outlines*, and that the less like lines your's appear the truer will they be to your model; but do not run into the opposite extreme, or what is usually termed "woolliness."

46. Carefully avoid a kind of flesh painting, sometimes much admired for its touchy, sparkling effect, which destroys truth of texture, and makes everything appear to be formed of polished stone or metal.

47. Remember that flesh is not as brilliant in colour as flowers and fruit, nor as transparent as pearls, and that the imitation of such things is not painting *flesh*, which has distinctive character and beauty of its own, no less difficult to represent, or less pleasing to every eye when successfully displayed.*

48. "Avoid *the chalk*, the *charcoal*, and the *brickdust*." — *Sir J. Reynolds.*

49. Indistinctness is not softness.

MAXIMS FOR BACKGROUNDS.

50. "If the backgrounds of your pictures necessarily consist of distant objects, they should, I think, be indistinct, and slightly executed." — *W. M. Craig.*

51. The liberty taken with the "*horizontal line*" of perspective in the backgrounds of portraits is great and common; as this indicates the level of the spectator's eye, you should carefully place it upon that height in the picture which was represented by the eye of the camera in taking the portrait, and thus aid the general effect of truthfulness.

52. The figure should always stand prominently before the background, which should, consequently, be unobtrusive and retiring, with but few details and no pure colours; dark backgrounds give the more forcible effect, but they should not contrast the lights too harshly.

53. "Bright colours may be lowered to any tone required, but *dirty* colours can never be made to look bright."—*Mrs. Merrifield.*

* *Flattered Portraits* (if required as portraits) are a great mistake, they are never satisfactory, and for this reason, they are required to be made *unlike* by flattery and at the same time to be as *faithful resemblances* as if they were *not* flattered; most artists have experienced this vexatious fact. Resemblance under *favourable circumstances* is another thing.

Letters to a Young Photographer.

No. XVI.

MY DEAR EUSEBIUS,

You are now about to enter upon ticklish and debateable ground. The rival claims of albumen and collodio-albumen have to be settled by preference or experience: preserved collodion and dry collodion have many rival partisans, who respectively exaggerate the merits of the subject of their preference. I shall proceed to describe the process introduced by M. Taupenot, which is usually spoken of as a dry collodion process.

By an ingenious combination of albumen and collodion, a preparation is obtained which possesses the properties of both these bodies; combining the rapidity of collodion with the fineness of albumen, with so complete a dessication of the sensitive coating that it is scratched by the nail with difficulty. With these qualities there is the sensitiveness of the film retained for many months after immersion in the nitrate bath — a quality that cannot be too highly prized by the travelling photographer.

The cleaning of the glass is of primary importance in this process, as complete success in manipulation is mainly dependent upon a perfectly clean plate. Much of the discredit thrown upon the process is due to the failures which arose from blisters, &c., caused by the plates being imperfectly cleaned. It is amusing to read of the numerous remedies proposed for this inconvenience: they all resolve themselves into one — good cleaning.

It must be admitted, however, that greasiness is the principal cause of blisters; therefore it is advisable to clean the plates first in a strong alkali, in order to remove every trace of grease. Dissolve one ounce of American potash in a pint of water, and immerse the plates in it for several hours. The solution will answer for several lots of plates. Upon taking them out rinse them in a vessel of clean water, and then rub them over with whiting, contained in a linen or muslin bag, and let them dry. They can be kept in this condition for any length of time, and polished when required for use with cotton wool. If the plates have been used before, the film must be scraped off with a knife, and if they are very foul, it may be expedient to clean them with tripoli powder and nitric acid, and afterwards proceed as indicated above, taking care to remove all the dust that accumulates on the edges of the glass.

When you proceed to apply the collodion to the glass plate, go over the surface with a soft brush kept for the purpose, to remove any particles of dust or flue that may adhere to it, and breathe upon the plate to see if its surface is in a state of purity. It is necessary that the collodion be very adherent to the glass; an alcoholic collodion is not adapted for this process. It should be iodised with iodide of ammonium or potassium, but not with cadmium. Here is a formula for the collodion, which has yielded uniformly good results:—

Gun-cotton	1	drachm.
Ether	12	ounces.
Alcohol	3	"
Iodide of ammonium	1	drachm.
Bromide of ammonium	15	grains.

This collodion being very fluid, and containing much ether, evaporates very quickly, and it must be applied to the glass plate with some dexterity, in order to insure a uniform layer. Pour the collodion on to the middle of the plate—it will quickly extend to the edges. Have ready a stoppered bottle, into which place a clean glass funnel, with a piece of cotton wool loosely inserted in the neck of it. Into this you will drain the superfluous collodion from the glass plate, which will serve for use again upon the addition of a little ether, to make up for loss by evaporation.

The nitrate of silver bath is prepared as usual, of a strength of thirty to thirty-five grains to the ounce of water, and saturated with iodide of silver. If it prove alkaline to test paper, add a drop of acetic acid.

The collodionised plate immersed in this bath is allowed to remain five minutes, then taken out and drained; it is then carefully immersed in a dish of distilled water, and gently moved about in it; passed into a second dish of distilled water, and then washed under a stream of filtered water, finishing with two or three rinsings of distilled water. It is next placed at an angle on a piece of blotting paper to drain. It is then ready for the application of the albumen.

At this stage of the process I may stop to remark that it has subsequently been found an improvement not to wash off the silver solution entirely, but to dilute it by applying a *limited* quantity of water for that purpose. Full particulars of this improvement you will find in this Journal under the head of *The Fothergill Process.* You prepare the albumen for the next coating as follows:— Beat the whites of a given number of eggs into a froth; when strained take

Albumen	4	ounces.
Distilled water	5	drachms.
Iodide of ammonium	16	grains.
Bromide of ammonium	5	grains.
Aqua ammoniæ	2	drachms.
Loaf sugar	50	grains.

You may substitute salts of potassium for those of ammonium if you prefer to do so. In that case you must add to the solution of iodide of potassium a few crystals of iodine, which will prevent the formation of an infinite number of small spots in the film, which are so very annoying to the operator when they do occur.

The salts and sugar are dissolved in the water, the aqua ammoniæ then added, and when all are dissolved the whole is added to the albumen, well shaken up together, and then allowed to subside for four and twenty hours; then draw off the clear liquid by means of a syphon. So long as the odour of ammonia is perceptible, the mixture will keep in good condition.

Experts in photographic cookery have boasted of the superior attractions of fermented albumen and honey. If there are any advantages in this preparation, I have failed to discover them.

Coating the plate with albumen is a piece of manipulation that requires much tact to perform successfully. I do not think I can impart the requisite instructions in a letter, I will, however, give you a general notion of what is required, and leave the rest to your sagacity.

Take the collodionised plate and hold it by an angle opposite to that by which it was held when collodionised, pour the albumen upon the right upper corner, and let it flow to the left, and then by slightly inclining the plate let it flow in an even layer to the lower angles, allowing a little of the surplus, which will carry with it a few drops of water, to drain off — then incline the plate in the opposite direction so that the albumen flows in a uniform layer to the upper

edge of the plate; then by elevating the lower end cause the albumen to flow towards the hand, and allow the excess to flow off into a clean bottle, which when filtered will serve again. It must not be mixed with the original albumen.

When the excess of albumen has drained off, place it on an angle on blotting paper and allow it to become dry. In this state the plate is not sensitive, the iodides in the albumen destroying the sensibility which the collodion had acquired in the nitrate of silver bath. The plates may be kept indefinitely in good condition.

In description, the details make this process appear very long and tedious, but you will not find it so in practice. The plates, when dry, must be preserved in a well closed box, sheltered from dust and humidity.

When you require to make use of the prepared plates they must be sensitised anew. You may employ the same silver bath as before, or you may make another for the purpose, by taking

Distilled water	25 ounces.
Nitrate of silver	2 ounces.
Acetic acid	2 ounces.

The plate must be immersed in this bath with much care, and without hesitation, to avoid markings.

Upon removal from the bath the plate is allowed to drip for half a minute, then rinsed in two successive dishes of filtered water, then drained. Let a gentle stream of water from a washing bottle wash the surface of the albumen with two clear washings of water, then set the plate on an angle to dry in the dark.

When well prepared these plates are much more sensitive than ordinary albumen, but less sensitive than wet collodion. With a portrait lens, on a fair clear day, a picture may be obtained in two or three seconds. With a landscape lens, one, two, or three minutes will be required, according to light, diaphragms, &c. The plates will retain their sensitiveness several months, but they eventually lose a portion of it.

The plate is developed with the following solution:—

Water	5 ounces.
Gallic acid	7 grains.
Pyrogallic acid	2 grains.
Alcohol	5 drachms.
Acetic acid	1 drachm.

Add a few drops of the silver solution to the measure containing the requisite quantity of this for developing a plate. The formula may be varied according to circumstances.

A larger proportion of pyrogallic acid will yield more intensity in the blacks. If the plate be over-exposed, the gallic acid must be diminished, and the acetic acid increased.

Developing is most successfully performed by immersing the plate in the solution contained in a horizontal bath. I think that developing is the most difficult part of the process, and you must expect many failures before you succeed.

The fixing is performed with hyposulphite of soda. If the picture be strong, the solution may contain 10 per cent. of hypo.

Photographic Glossary.

Pins—As pins are very extensively employed in photography it is worth mentioning that preference should always be given to black pins, which, being protected by a varnish, are not readily acted upon by the various chemical agents with which they are placed in contact.

Pipe Clay—A well-known substance employed in photography to clear solutions of silver which have become discoloured by various organic bodies, such as albumen, gelatine, honey, &c.

Platinum—A dense white metal, very malleable, ductile, and infusible. It is the heaviest substance known. It is, like gold, insoluble in ordinary acids, but soluble in *aqua regia.* Platinum forms two compounds with oxygen and chlorine.

Positive—A positive photograph is one in which the position and light and shade of an object are reproduced in an image under the same aspect as they present in nature, and not reversed as in *negatives.* Positives are direct and transmitted; the first are produced upon glass, the second upon paper.

Positive Printing—The production of pictures upon paper from negatives on glass. One of the most delicate, difficult, and important branches of the art of photography.

Potassa: Potash—An oxide of the metal potassium, a very important substance, and of great practical utility. It is a fusible, volatile, white substance, which evolves great heat when moistened with water; forming the hydrate or caustic potassa, which is a white solid substance, very deliquescent, and soluble in water and in alcohol. It possesses alkaline properties in a very high degree, and completely neutralises the most powerful acids.

Proof Spirit—Alcohol or spirits of wine which contains forty-nine-and-a-quarter per cent of real alcohol, and is of the specific gravity of 0·9198, at 60°, is termed *proof spirit.*

Pyrogallic Acid—When gallic acid is exposed to a heat of 420° Farhenheit, or thereabouts, it is resolved into carbonic acid, and a new acid which sublimes in brilliant white crystalline plates. To this product the name of pyrogallic acid is given. It readily dissolves in water.

Pyroxyline: Gun Cotton—When carded cotton is plunged for twelve or fifteen minutes in monohydrated nitric acid, it remains unaltered in appearance, but a certain quantity of the acid becomes fixed. It is then freely washed in water, and carefully dried in the atmosphere; although unchanged in appearance, it is found to be greatly altered in its properties: it has become a highly explosive substance, like gunpowder. It is now insoluble in water, in alcohol, and in acetic acid, but soluble in ether mixed with alcohol, forming *collodion.*

Reduction—A chemical process by which a metal is separated from its combinations with oxygen and other bodies. Metallic ores are reduced to the metallic state by the agency of heat assisted by fluxes, and by other means. The blowpipe is a ready means of reducing specimens of minerals, salts, &c., to the metallic state.

Salts—Bodies formed by the union of acids with basic oxides—whether these latter be alkaline, earthy, or metallic. Salts are neutral, acid, or basic. They are grouped or arranged in two classes—In the first are placed those constituted after the type of common salt, which consists of a metal (*sodium*) and a salt-radicle, as chlorine. In the second stand those which, like sulphate of soda and nitrate of potassa, are supposed to be combinations of an acid with an oxide. The first are called *haloid* salts, the second *oxygen-acid,* or *oxy-salts.* There are compounds which contain sulphur in the place of oxygen, and these are also regarded as salts: they are termed *sulphur salts. Acid* salts are those in which one atom of a base is combined with two or more atoms of an acid, as in bitartrate of potash: *basic* salts are those in which the proportions of base are in excess of those of the acid. Salts often combine together and form *double salts,* in which the same acid is in combination with two different bases.

Saturation: Saturated Solution.—When a liquid has taken up as much of a solid body as it will dissolve, the liquid is said to be *saturated,* and forms what is called a *saturated solution.* Generally speaking, more of the solid body is dissolved when the liquid is at a high temperature than when it is low, but the excess of solid is deposited again as the liquid cools down. Sometimes when a liquid is saturated with one substance it will dissolve a notable quantity of another added to it.

New Books.

The Photographic Art: its Theory and Practice, including its Chemistry and Optics, &c., &c. Originally compiled by M. Sparling, revised and corrected to the present date by James Martin.
London: Houlston & Wright, Paternoster Row.

This is a title embracing a very wide field of operations, and though we have had this book for some weeks before us, it has been impossible to notice it fairly at an earlier date from the mass of matter that it was requisite to peruse. It is, as indicated above, chiefly a compilation by one hand re-arranged by another. The principal novelty in the present edition is a concise chapter upon the chemical part of photography—in fact so concise that the author has occasionally been led into making statements that are of rather too sweeping a character. For instance, we find, at page 17, "*Ammonia* is or ought to be *only* used photographically for the purpose of making ammonia-nitrate of silver." This is a proposition to which we can by no means assent; besides being much employed in composition, it is valuable also as a cleansing agent, and especially for use with albumen.

The treatment of residues will be found useful by many.

The optical part had better have been omitted, as it is neither altogether popular nor correctly scientific—the old error respecting the elliptical surface for avoiding spherical aberration is again repeated, oblivious of the fact that such a remedy does not apply to *oblique* rays, the very ones

that are the bugbears of opticians in general and photographic ones in particular. We also find the startling statement that to obtain *perfect* achromatism it would be necessary to have *seven* prisms. Query—Is it clear that it could even then be made *perfect*?

There is a useful diagram at page 41, showing what frequently puzzles those ignorant of optics, how it is that a lens covering fairly a given parallelogram, say nine by seven inches for instance, will not necessarily cover a *square* of nine inches.

We are glad to perceive Mr. Martin, from experience, strongly recommends the use of a crotchet (as it has been called) of our own, the construction of tripods of *fir*, the reason being that it is cheap, light in weight, and quite strong enough for the purpose.

We do not, however, agree with him in preferring patent plate glass to flatted crown, which he says will answer very well as a substitute; we should reverse these recommendations, heretical though they be, because the latter having a *natural surface*, whilst the former has a *wrought surface*, there is less liability to stains from want of perfect cleanliness, less difficulty in cleaning and less cost. For very large plates only we fear it is too thin.

We might go on making comments almost *ad infinitum*, but want of space will not permit us to continue farther. We fear that the novice in selecting this work as his *vade mecum* may be at little trouble with an *embarras de richesse*, but it certainly contains all he is likely to require, and is even a useful book of reference to the more practised photographer.

Foreign Correspondence.

Paris, August 10, 1859.

PHOTOGRAPHY will doubtless derive some benefit from the researches of M. Edmond Becquerel on *Phosphoresence.* That gentleman has just published his third *Memoirè* on "the various luminous effects resulting from the action of light on bodies"—the substance of which I will endeavour to communicate to you.

It will be remembered that these researches were undertaken with a view to determine the nature of the luminous properties which result from the action of light on bodies, by which the latter, in their turn, act as new luminous sources. A very large number of minerals and salts display luminous effects, while other substances, as the metals, exhibit none. Further light will doubtless be thrown on this fact by the researches of Dr. Otto Hagen, on the absorption of light by crystals. It must be observed that the emission of light in the phosphoroscope is limited by the sensibility of the retina, by the intensity of the active rays, and by a certain duration of persistence due to the impression received by the body. This duration can be represented by a determinate time only in what concerns the effects appreciable by the eye; for we may conceive, that according to the influence of the radiation the bodies continue to emit luminous rays, the intensity of which is too feeble to impress the retina. On the other hand, in supposing that the bodies are invisible in the phosphoroscope, we can not affirm that they have received any modification, for the light may have excited vibrations of a different velocity than that of the luminous rays, of which the length of the undulation will be greater than that of the active rays, which vibrations will be capable of giving rise to effects of heat or other molecular actions yet unknown. The following conclusions are deduced from these new researches:—

1. When a body is struck by light, by virtue of the action then imparted to it, the body may act as a luminous source, in emitting rays of various degrees of refrangibility, the duration of which is very variable (it may be less than one-fifth of a second, or exceed several hours), and the intensity of which is dependent upon that of the incident light, and always feebler than the latter. Every substance does not give appreciable effects: among those which possess this power in the highest degree are the different combinations of earthy and alkaline bases, and a certain number of metallic salts. Most other translucent and transparent substances, particularly those of organic origin, exhibit other feebler, though sensible effects. The metals and highly-coloured substances give rise to no effect.

2. The solid form of bodies is best adapted for showing these phenomena: still the effects observed in the ultra-violet rays with many fluids prove that the latter are endowed with actions of this kind, without being apparent in the phoroscope. On the other hand, when we employ a peculiar arrangement, with the aid of an apparatus of induction, the oxygen acquires the power of emitting light, which continues even after the passage of the electricity.

3. The luminous effect belongs to the mass of the body submitted to experiment, and is not merely a surface action: it takes place whatever be the incidents of the active ray, and is dependent only on its refrangibility and intensity.

4. The effect observed in the phosphoroscope after the action of the incident light exists, nevertheless, in a permanent manner during the influence of the latter. This conclusion results from the identity of the optical effects observed when certain bodies are placed in the phosphoroscope, or continuously exposed to the action of the violet rays.

5. A body submitted to the action of light may emit rays of unequal duration. This is the cause of the changes in tone of such a body when the velocity of the disc of rotation in the phosphoroscope is changed: it may be observed in the diamond, in the carbonate, phosphate, and silicate of lime, carbonate of strontian, hydrate of potassa, &c.

Among the effects observed in the same body we may often distinguish two predominating hues; but there may be more, as in the case of fluoride of calcium. These different luminous effects exist together, and are not produced successively; they appear in the phosphoroscope one after the other, by virtue of the unequal persistence of the rays emitted.

6. There is no relation between the refrangibility of the rays emitted and greater or lesser persistence of the latter. Every substance has its own peculiar action: either it is the most refrangible rays whose rays are most prolonged (carbonate and silicate of lime), or the contrary effect takes place (diamond, bisulphate of quinine, platino-cyanide of potassium). With the fluoride of calcium the rays of mean refrangibility have the least persistence; the least refrangible rays have a little longer duration, and follow the most refrangible rays.

7. A body may be influenced by rays of different refrangibility, and under the action of the latter emit rays which differ not only in duration but also in refrangibility; in this case the body presents rays the refrangibility of which is only less than that of the active ray, or, at the most, equal to it. Thus, in successively impressing a body with violet, blue, green, and other rays of decreasing refrangibility, the refrangibility of the rays emitted in virtue of the action peculiar to the body may vary, and, if it varies, exhibit only rays of less and less refrangibility, as prismatic analysis demonstrates.

In other words, the prismatic images given by the rays emitted by virtue of the action of the simple incident rays diminish in length from the violet side in proportion as the refrangibility of the incident ray diminishes and varies from violet to red. The changes of colour observed in caustic potash, fluoride of calcium, and sulphide of calcium, are due to this cause. Thus, when a body is impressed by orange rays, it can emit only orange or red rays; if it be impressed by red rays, it can exhibit only the latter colour. elevation of the temperature, which are not subject to the same laws.

In certain cases, in which is observed the emission of rays, in which the length of the undulations was less than that of the emitted rays, it is ascertained that the luminous phenomenon was complicated through the effects of the phosphorescence by the

8. The limits of refrangibility between which bodies are impressionable, that is to say, the length of the active solar spectrum, depend on the nature and molecular state of the body: in general, the limits are much more extensive when the light emitted by the body has a less refrangibility (as in alumina and aluminate of magnesia), without there being fixed rules in this respect. On the other hand, the spectra of the active rays may present many maxima of action, as is proved by phosphate of lime and leucophane.

9. The changes of colour certain bodies present, in consequence of the difference in the refrangibility of the active rays, are much greater when the bodies emitting the rays have more dissimilarity of refrangibility, and of which the prismatic images are more extended; but with bodies like alumina, the compounds of uranium, &c., in which these conditions are not fulfilled, the changes are scarcely perceptible.

10. Every body has its own peculiar action, and the composition of the light emitted by it may serve in certain cases to specify its physical state and composition: such is the case with albumen and certain of its combinations, the diamond, &c. In some instances, it may be seen that there is an action in a body due to its chemical composition and an action dependent upon a peculiar molecular state. Thus, for example, the diamond always gives an emission of slightly refrangible rays (orange and yellow), an effect due to the nature of the substance; and sometimes, only, conjointly with this effect, an emission of rays more refrangible (blue), of less duration, dependent upon a molecular state of the body, and to which is due the blue colouration in the ultra-violet portion of the spectrum. Other substances, as carbonate of lime, act in a similar manner.

11. The identity in composition of the light emitted by bodies placed in the phosphoroscope or exposed to the extreme violet rays, permit the conclusion that the causes of the light emitted by phosphorescence and by fluorescence are the same. Such are the luminous effects given by alumina, aluminate of magnesia, the compounds of uranium, and the diamond, which are identical, and lead to the same series of black rays and luminous lines in the apparatus and in the most refrangible solar rays.

12. Rays emanating from bodies in virtue of their peculiar action, when these bodies are placed in the phosphoroscope, acting, as it were, in a continuous manner, may give rise to other effects than to impressions on the retina: they render the phosphorescent substances luminous, and produce chemical actions upon impressionable matters, through their refrangibility and intensity, like the solar rays. Another *Memoirè* will be specially occupied with those effects which present a remarkable example of the transformation of physical forces in to each other.

These conclusions show the great importance of these new researches, the results of which may be brought to bear upon the study of many questions of molecular physics, and serve to throw light upon many points of chemical analysis, and permit us to grapple with phenomena which concern one of the least known branches of optics. J. P.

PROPOSED UNIVERSAL COLLODION.

To the Editor.

Sir,—If the subject of collodion be not yet exhausted, and I am afraid from all I hear that that great desideratum, an universal one, is still looming in the distance, a few jottings from my note book may not prove unacceptable. The great object to attain in making a good collodion which shall have any pretensions to be called universal, that is to suit all operators, appears to me to be to get one that shall be extremely *soft, intense,* and keep tolerably well; for, generally speaking, if we put one description into two operators' hands, one will say it is excellent, all that can be desired, whilst the other will say it has no intensity whatever. If we now alter it to suit the latter person, the former will complain of want of middle tints. *It is not so difficult to make separate collodions to suit both,* but the difficulty is to get one and the same collodion to work well with both operators.

Having been experimenting for some time I have been inclined to follow a certain track, which seems to me to be the nearest approach and the most likely road to lead to success; and, first, I would lay it down as a rule that it is an impossibility for any one, with any collodion, any sort of nitrate of silver, a developing solution made up any recipe, to get sure results at all times; all must be properly balanced to before we can expect success.

Having made these remarks, I would commence by saying, that *softness* is of the greatest consequence in a good collodion; for it is possible by increased development and pushing with nitrate of silver to obtain intensity, but very difficult to obtain middle tints in a hard collodion, even by a prolonged exposure, the middle tints being weak, and the picture harsh, and devoid of atmospheric effects. This has been endeavoured to be overcome by the use of a bromide; and although by increasing the strength of the pyrogallic developer to the original Archer receipt, namely three grains to the ounce, with a little more acetic acid—a *sine qua non* when a bromide is used, but which does not appear to be generally recognised—a good picture may be obtained, as quickly as with an iodide; still it will be found much easier to get a successful result with the latter alone under some conditions of light, and, if the plan which I adopt be followed, both softness and intensity will be obtained with very little trouble. I first start with the softest pyroxyline I can get. I have been in the habit of using paper prepared with equal parts of weak acids at a low temperature. My reason for using paper has been from its giving a more soluble product than cotton wool; but since the discovery, by Mr. Hardwich, of the increased solubility of cotton wool made with excess of diluted sulphuric acid, and its superior keeping qualities when made into collodion, I am about to give the latter a trial, as I have just used up all my old stock made of paper. I cannot say, however, that I have met with that difference in pyroxyline made from paper that I have heard complained of: possibly making it only in small quantities at a time may account for this, and also washing with boiling water, which I think of great consequence in getting out all the bitter principle in the pyroxyline, which is not soluble in cold water or even ammonia. The greatest amount of water in the diluted acids of Mr. Hardwich I am told produces the softest collodion, which I should therefore prefer. The next thing is to dissolve it in ether, adding a large excess of alcohol; this opens the pores of the film and increases the intensity without giving a hard picture like the fibre prepared at a high temperature. It is doubted whether increase of alcohol after a certain amount does any good; it certainly may cause the collodion to be both slower and less intense if the pyroxyline be added in the same quantities as is necessary in an ethereal one for then the film will be too opaque, but I have found *more* alcohol and *less* pyroxyline both quicker and more intense than the contrary. Should this with some not be found intense enough, then neutralising the bath with carbonate of soda and adding acetic acid will be found of great use; for no one ever complains of too much intensity, as water soon rectifies that, and there is never any fear of staining with an alcoholic collodion.

The collodion I have been using contains ether three drachms, absolute alcohol three drachms, pyroxyline six to eight grains. Iodising solution—iodide of cadmium two-and-a-half grains, iodide of potassium two grains, absolute alcohol two drachms; triturate the two salts together and add them to the alcohol, shaking occasionally for two or three days.

The principle which I wish to establish from the above is to endeavour to obtain intensity by every means short of tampering with the softness of the pyroxyline, as there is no other means at present that I know of, of getting rid of *white washed leaves in foliage on a black board* as is so readily obtained in photographic views.

Trusting this may be acceptable to your readers,—I am, yours, &c.

FRANCIS G. ELIOT.

PHOTOGRAPHIC NICKNAMES.

To the Editor.

Sir,—The enclosed appeared in a Carlisle newspaper. Is it not a pity that "artists!" (?) cannot keep to words that every one can understand? I wonder what his "Photeikons" are like.—I am, yours, &c.

August 1st, 1859. C. A. B.

"Photeikons! Photeikons!!—M. F——'s Crystal Palace Gallery and Photographic Artarium is completed, and expressly fitted up for taking Portraits in any weather. Open from daylight to dusk. Opposite the Church, Botcher Gate, Carlisle—15.4."

[Will not the old proverb, "Good wine needs no bush," apply to the above *et hoc genus omne?*—Ed.]

LEAKE'S TENT.

To the Editor.

Sir,—Will you kindly permit me, in answer to your correspondent, "Oxoniensis," to say that I have, since I *first invented* the "dark tent" to which he alludes (nearly four years since), sent out numbers to different parts of the country, and some to the continent, and it is quite possible, therefore, that he may have seen one in use "of exactly the same construction." I think, with all due deference, he has chosen a somewhat illogical method of proving that I am *not* the original inventor. But, however, sir, if *a sketch and description* of the "trifle" will interest your readers, or help them in the practice of out-of-door photography, I shall be most happy to forward them, *with* my *latest* plan for *fixing the moveables.*—I am, yours, &c. J. H. LEAKE, Sen.

25, *Upper North Street, Poplar, August* 3*rd,* 1859.

[We shall be happy to receive the communication referred to.—Ed.]

BELMONTINE NEGATIVES.

To the Editor.

Sir,—You will please accept with the enclosed my best acknowledgments for your valuable suggestions appended to my paper.

Unfortunately there is an error in one of the formulæ, No. 6:—the nitrate of silver should be two scruples instead of eleven grains. Pray have this corrected in your next for me, though probably in a few days I may be able to send you an appendix. The enclosed is not quite after your formula, as the materials were not at hand, and there is some difference also in each of the other forms. The *mode* of operating has been followed which will be satisfactory to you.

I am endeavouring to still further shorten the method, by using an emulsion of the paraffine and albumen solutions together, and a picture now on the glass seems to promise good results, which, if so, will save one item in the process. In a day or two I hope to give you some proofs and some further details.

You must excuse me if I am not quite satisfied with your remarks on the positive appearance of some of the pictures: I am seeking for a solution of one or two points connected with it. There will not be time for me to send you anything more at this moment, and you will not, I am sure, object to soak the specimen sent a little longer in water.

(Turner's paper.) Picture taken at five o'clock in the afternoon, good sunlight; two minutes exposure; developed in fifteen minutes; would apparently have borne the pyrogallic more without discolouration; an alteration in each of the formulæ; the mode the one suggested by yourself; it seems the iodide is not quite removed; half-past six o'clock in the evening.—I am, yours, &c. * * * M.D.

Southampton, August 1*st,* 1859.

[Altogether a *very* promising result; fine detail; total absence of granulation; fair intensity; capable of further development if needful; and good half-tone.—Ed.

OPERATING DIFFICULTIES.

To the Editor.

Sir,—Seeing how kindly you answer your photographic correspondents in their difficulties, I take the liberty of asking you to assist me in getting out of mine.

In taking portraits in my operating room, which is boarded round to the height of seven feet, when the sun is shining right on it (from eleven o'clock till three) I shade it off entirely with white calico; but the pictures I get then are quite flat and grey, and do not even look well on the ground glass; but when the sun has gone off my yard, and the calico taken down, I get first-rate pictures, and the image looks quite clear on the ground glass. By suggesting a remedy in an early number you will oblige yours, &c. W. T. G.

Bolton, August 9, 1859.

[The boarding round the sides shuts off all lateral light, and the white blinds over the roof have the same effect as a *very dull day* in producing flat results.

Remedy.—Paint your room white opposite your sitter, and, instead of shading the whole room when the sun shines, be content with placing your sitter only in the shade, and let the sunshine stream into the rest of the space. It may be inconvenient, but it is the only remedy, except replacing the wooden sides with glass.—Ed.]

WOODWARD'S SOLAR CAMERA.

To the Editor.

Sir,—I have given some little account of Woodward's solar camera, and I know in time it will, from its merits, work its way into general use. Please find a space for it in your wide-spreading Journal.

I fear in speaking of the above I may, by some, be thought interested, being the maker and agent for the sale; still it is not a reason why the truth should be locked up. I believe I was the first in this country to purchase one of these instruments from Mr. Anthony, of New York, for which I paid him £15 in English money, and this, by adding duty and other expenses, amounted to fully £17. The same sized instrument is now offered for £13.

On receiving it I sent it to several meetings of various photographic societies to push it into notice, but little was said or thought about it.

I had an idea that I could very much improve upon it. I set to work, constructed two or three instruments, and made a trial with one of them; but having met with little success, I concluded that it would be more satisfactory if I built a dark room expressly for it, which I did at a great expense, and with this room succeeded no better. I then laid it on one side, putting it down as one of my follies. The American camera I had never used, although it had been in my possession full eighteen months.

At length the patentee, Mr. Woodward, arrived in this country, and I told him how unsuccessful I had been in all my attempts to work the solar camera. He offered to put it in use immediately. I even then thought I was going to waste more time and material, but I very soon found I had not the least idea of its simplicity and wonderful performance. The result of that day's work was truly astonishing, so much so that from that time I have wedded myself to it, and I feel convinced that, when it becomes more generally known, all photographers, lithographers, and painters on canvas or other surfaces, will provide themselves with one, and eventually artists will attach one or two to every suitable window in their house, and take advantage of all the light that comes.

About six years back I contrived an apparatus to enlarge photographs by a condenser and gas light, and I have no doubt many others have increased photographs in size; indeed, all say to me, when I am recommending it, oh, I have done this years ago! I admit they have done something of the sort, but can one of them show a portrait of any size without retouching that can bear comparison to one produced by this instrument?

I have shown it to several who were most difficult to persuade that it was anything new or worth notice till they saw it at work, and also saw the result. The first question subsequently put to me was—how soon can I have one? I do really believe that there is no photographic instrument heretofore discovered that will be of such service to the artist.

I have several large lenses; one, I believe, the largest in the country, which should bring me one hundred guineas. It is an exceedingly good one; still it is impossible to produce with this instrument, or any that can be made, a picture equal to that by the solar camera at £21, or even that at £13. The difference between the two sizes consists in the larger one admitting more light, thereby doing its work much more quickly.

If any photographer who may be passing through Liverpool be desirous of knowing the truth of this, I shall be most happy to convince him.—I am, yours, &c. JOHN ATKINSON.

37, *Manchester Street, Liverpool, August 2nd*, 1859.

[We received a visit from Mr. Woodward when here, and have also been invited by Mr. Kilburn to see the working of the instrument above described, but were unfortunately absent from town, and ill health and other pressing occupations has hitherto prevented our attention to it. We propose taking the earliest opportunity of examining the apparatus, but must confess we are not sanguine about finding any novelty, much less ground for a patent, as the subject is one to which we directed our endeavours with considerable success five or six years ago. See two papers in the first volume of *The Journal of the Photographic Society*, one by Mr. F. H. Wenham, and one of our own, both read on the same evening at the meeting of the Photographic Society.—Ed.]

ANSWERS TO CORRESPONDENTS.

J. L. Fysh.—See Mr. Church's article in the present number.

J. P. D.—A twin lens camera by all means.

John Bailey.—Your complimentary remark to our publisher has been forwarded to us by him. We return our best thanks.

P. F.—We never made the assertion alleged. We do *not* approve of the paper named.

Mayflower.—Certainly not. How can you expect it? See reply to G. Jones. Our time is far too valuable to waste in the way you propose.

* * * M.D.—Received too late for insertion in the present number. To appear in our next.

A Young Hand.—Your fault is under exposure. We should say at least twice as long as the time you gave for those specimens sent.

Argent.—A newly made nitrate bath is seldom fit for use in less than twenty-four hours after it has been made.

Ed. Taylor.—You can work more deliberately with an alcoholic collodion than with one containing excess of ether.

Crayon.—A treatise "On the Principles of Form in Art," is published by Messrs. Winsor and Newton, London. You will find all you require in it.

Bronte.—Castor oil is the only fixed oil soluble in alcohol; but all the essential oils are soluble in it.

S. S.—Pyroxyline is sometimes made with Swedish filtering-paper, but cotton is preferable because it is more uniform in composition.

T. L., Cannonbury.—Best thick Saxony paper—Knight's, Foster Lane; or else use Hollingsworth's paper—Cox, Skinner Street, Snow Hill. Formula in our next.

Cosmos.—Sulph*ides*, carb*ides*, used to be called sulph*urets* and carb*urets*; their nomenclature has recently been changed, to make them harmonise with chlor*ides*, ox*ides*, cyan*ides*, &c.

F. Franks.—You will perceive, by a note in the present number, that the same gentleman is at work upon the hint thrown out. A paper on the subject will appear in our next. The result is capital.

Clara Jones.—Photographic printing is an occupation well adapted for a female—in fact many of the professional operators employ females for this branch of their business in preference.

H. Moxon, Richmond.—If the collodion remains of a pale blue colour after long immersion in the nitrate bath, it shows the collodion is not sufficiently iodised.

Buffon.—The spots on your plates doubtless arise from dust left on them in cleaning. Use a soft brush to remove it before applying the collodion.

Pilgrim, Havant.—The nitrate of silver adherent to the collodion film dissolves the iodide as it dries, hence the necessity for a preservative solution.

G. H. Scriven.—The formula for Maxwell Lyte's toning bath is given at page 67 of the present volume. In preparing it, be sure that the chloride of gold is *neutralised to test paper* by the addition of solution of carbonate of soda, before adding it to the phosphate of soda.

G. Jones, D. Wright.—We cannot undertake to examine any lenses or other apparatus that may be sent to us for that purpose, except our consent be first obtained—and then only for the publication of such results as we may find of *general public interest*.

H. Hulme, Yarmouth.—Your lens has probably an imperfect focus, arising from the separate glasses being unadapted for each other. Cannot you return it to the maker, or get it exchanged? You could not expect much for the money you paid for it.

J. Sefton.—So many circumstances influence the time of exposure that it is impossible to lay down any fixed rules. Two or three experiments ought to suffice to enlighten you on this head if you know a good negative when you see it.

Paterfamilias.—We consider that you cannot do better than cultivate a taste for photography in your son. His sisters will also very likely be smitten, and you will thus produce a home attraction that will in all probability counteract the roaming tendency you deplore. Moreover, the associates among whom he will be thrown as a photographer will also tend to direct beneficially, without thwarting, his roving fancy.

A. H. B.—The error in the formula for obtaining pure whites in direct positives consists in ounces being given to each item instead of drachms. It should stand thus:—

Water	12 ounces.
Alcohol	5 drachms.
Acetic acid	5 "
Sulphate of iron	4 "
Sulphuric acid	1 drachm.

☞ *All* Editorial *Communications*, Books for Review, *&c., should be forwarded to the Editor*, GEORGE SHADBOLT, 2, *Upper Hornsey Rise, London, N.*

All Advertisements *and* Letters *on the* Business *of this* Journal *should be addressed to the* Publisher, 32, *Castle Street, Liverpool.*

THE PHOTOGRAPHIC JOURNAL.

No. 101, Vol. VI.—SEPTEMBER 1, 1859.

The men of Manchester are not of a sort to lag in the rear when they ought to be in the van: in proof of this assertion, witness the establishment of the Art-Treasures Exhibition a few years back.

The managers of the Art Union of Manchester, as will be perceived on reference to our advertising columns, contemplate distributing, as part of their prizes for the current year, a certain number of *choice* photographs, bound in volumes. Although the council of the London Art Union last year made arrangements for presenting to a portion, or all, of the subscribers photographs of some kind, and consequently so far took the lead in introducing the thin end of the wedge, we cannot but regard the committee of the Manchester Art Union as being really the first public body formally to recognise photography as a branch of the fine arts — the London council having only permitted it to occupy the very subordinate position held by the Associate Engravers in the Royal Academy, they being allowed on sufferance, as hewers of wood and drawers of water, to *copy* the creations of those supposed to possess a higher order of talent: so in the London Art Union, the photographs allowed were strictly confined to "copies of works of art;" and these not distributed exactly as prizes, but in addition to, or instead of, the usual engraving presented to each member.

The Manchester Committee has thrown aside these restrictions altogether, and is content to let photographers that are artists indeed take their places besides their brother workers in the field of the beautiful, the simple stipulation being, "use your own weapons be they what you please, *but use them with your brains and conquer*."

That photographers are ready to take a place amongst artists we have before now seen, in fact we have already been singing to this same melody in the present number; and, though that place may not be as yet quite so sharply defined as some of their own productions, the niche is ready and will no doubt be worthily occupied. We trust that some of our brain-working manipulators will heartily respond to the invitation so cordially given, and prove to the world that the confidence displayed is not premature.

It has been already announced, in the official organ of the Photographic Society, that the Gallery of the Society of Painters in Water Colours has been secured for the Photographic Society's next exhibition, which it is contemplated to open in January, 1860. We should have been better pleased had the same rooms occupied last time (those of the Society of British Artists, in Suffolk Street) been retained, as not only is the space available in the latter considerably more extensive than the former, but we are convinced that the continual change of locality is highly detrimental to success as regards the attendance of visitors. We are pleased to observe that our good friend, the Editor of the Society's Journal, is urging upon practical operators the desirability of more general attention to the artistic treatment of subjects, and pointing out that direction as one in which there is a larger opening for an advance than in manipulation.

At the last meeting of the French Photographic Society, two papers were presented by M. l'Abbé Laborde, one being on the details of some experiments that appeared to the author to contain something novel, but which in reality simply demonstrate the fact that French landscape lenses are not so well corrected for spherical aberration as those made in this country; the second, a translation of which will be found in another column, being of a far more important character, very conclusive, circumstantial evidence being adduced to prove that the so-called "new action of light," of M. Nièpce de St. Victor, is due to the formation of *formic acid*. We are glad to find that the chief representatives of photographic science in Paris are beginning to admit that in this instance it is just possible that the celebrated physicist may have made a mistake.

In the pages of a contemporary photographers have been favoured by a recommendation to procure collodion from several sources and mix them all together, in order to acquire an article of average quality and uniform character. The recommendation is based upon the assumption that makers of collodion produce anything but an uniform article—an assumption, by the way, indignantly denied by one of the said collodion producers; but however that may be, we cannot perceive the soundness of the reasoning by which it is contended that the admixture of a dozen *indefinite* compounds can bring about the desideratum that the resulting mixture shall be uniform. If the assertion be only intended to apply to the quantity mixed at any one time, we are as far off from the desideratum as ever, for surely the same result would follow from mixing the various differing productions of any one maker. The proceeding appears to us very like cutting off the tails of the rabbits to make them uniform with the Guinea-pigs. In other words, spoiling the good in order that the inferior may not seem utterly worthless.

British Association: Aberdeen Meeting, 1859.—We are authorised to state that the time for sending in photographs for the Exhibition to be held in connexion with the above has been extended from the 1st to the 6th inst.

As a Scottish trip will certainly be highly popular at the present time, we have no doubt that photographers—professionals especially—will find this opportunity of bringing their works under the notice of many who would not otherwise see them at all of great advantage. Indeed, we regard the holding of an Exhibition in a locality not often thus favoured as sowing seed which, in the future, will yield a very abundant harvest.

PHOTOGRAPHIC CONTRIBUTIONS TO ART.

Since our last notice under this head we have been favoured with two or three new productions, which may truly be classed as belonging to the school of photographic high-art.

The resolution passed last year by the Council of the Photographic Society (and subsequently rescinded), relative to the non-admission into the Society's annual exhibition of such works as had been previously displayed publicly in London, is, we believe, operating at the present moment in some quarters as a restraint upon the publication of several works of considerable merit; but, as there can be no objection to the communi-

cation of a description of some of them, we purpose giving our readers the benefit of what we may call our private view.

While on the subject of the resolution to which we have made allusion, we may remark that, in our opinion, the error committed in the first instance, and of which the after reversal was not the proper remedy, consisted not so much in looking coldly on works with which the public had already become familiar, from their exposure in the windows of the numerous dealers in photographic productions in London, but in proposing to exclude them altogether. We conceive that every requirement would have been met on both sides by a regulation to the effect—"That *new* works, of equal merit, should take precedence of those that had been elsewhere displayed, even to the exclusion of the latter, in case of paucity of space." As we retired from the Council at the last annual meeting, we shall not have an opportunity of proposing such an arrangement for the ensuing occasion; but there are still on the Council many members with whom we were lately associated, who are animated with an earnest desire to promote the cause of photography, even though it may be to their own personal disadvantage, and we shall probably commend such a proposition to the notice of some of them.

We have been betrayed into a digression, not perhaps exactly foreign to our subject, but certainly into a track — speaking in railway phraseology — that terminates only in a siding. Let us resume the main line ; and first we will notice

"God Speed Him!"—by our photographic Rembrandt, which is a companion picture to Mr. Rejlander's previous production, *The Wayfarer*, and in which further details are revealed to us of the antecedents of the poor weary traveller in whose refreshment we formerly sympathised.

In the present work we are introduced to the faithful helpmate of the wayfarer, a woman past the middle age, sitting listlessly, apparently buried in anxious inward contemplation. She is neither thin, nor handsome, nor is she fashionably or gaily drest — no crinoline, no flounces, but clad in the homely cotton gown and woollen handkerchief befitting her age and station in life. Stretched over her left hand is a half-darned stocking, which hand, however, she also employs as a support for her chin, while the right hand, armed with needle and thread, lies carelessly and idle in her lap. On the right upper corner of the picture the subject of her thoughts is plainly hinted — her husband is seen toiling up the steep ascent in the distance; hence the exclamation which forms the title.

A tea-pot, two empty cups, and a dilapidated tea-caddy on the table, and a basket with some articles of clothing, the well-used Bible, and a half-open letter on a low stool beside it, all tend to intimate that the husband's journey has been hastily undertaken, and that the wanderer has not been allowed to depart without refreshment for both mind and body.

As a photograph this work certainly excels the former one in manipulation, excellent as that was. As a further revelation of the hopes and feelings that interest us it is highly satisfactory; but as a work of art we scarcely like it so well as the first of the pair.

Mr. Rejlander can well afford that we criticise: if we be right, no one will be more ready to take a hint; if wrong, we do not fear from him the imputation of ill nature.

The subject is illuminated from the spectator's *left* side, whilst the old man seen in the distance is visible through an oblong aperture, that may stand for a window, on the *right*. But this is not the way we read it; we take it *for a visible suggestion of the woman's thoughts*. If it be a window, the light on the figure is in the wrong direction; if it be, as we believe, a mental phantom, rendered apparent to the eye, the outline of the phantom subject is too hard and formal. In either case, Mr. Rejlander is too clever an artist not to be able to remedy the defect; and we have no hesitation in asserting that even in its present condition it is a pleasing and valuable addition to our art productions in the photographic department. As will be seen from a letter of Herr Pretsch's amongst our Correspondence, both negatives were taken with one of Professor Petzval's lenses, of the construction known as "orthoscopic," though the learned Professor repudiates the designation.

Next on our list we have a very charming composition by Mr. Henry P. Robinson, of Leamington, the producer of several very meritorious and highly popular conceptions, including that touching episode known as *Fading Away*. The new work is entitled

"Nearing Home," and consists of a skilfully-arranged group of three girls, resting on a mound in the vicinity of a town towards which their steps have been directed. They are evidently wearied with a long day's ramble: the principal figure is standing on the apex of the mound, with her back towards the spectator, her hat thrown aside, and, with her hands shading her eyes from the rays of the setting sun, is looking towards her home in the not very distant mass of houses. Of her two companions, one is seated with her face in profile partly turned towards the same spot, while the other, completely overcome by fatigue, has thrown herself at length on the sward, her head partly supported by her hand.

On the right is the slope of a hill, on which a female figure is reclining; and in the centre, at some distance, is a stream spanned by a bridge, a cluster of houses being seen on the opposite shore, while the horizon is bounded by a chain of hills covered with verdure.

This is of course a composition from several negatives, and the various gradations of intensity and general evenness of tone are beyond all praise. There is somewhat too great an amount of indistinctness about the extreme foreground, arising from a cause we may presently advert to; and, graceful as the group is, it has perhaps a little too much of artificiality to be perfect. The foot of the reclining girl, which unfortunately comes too near the angle of the picture, is, in consequence of the optical quality of the lens, considerably exaggerated in size. We cannot shut our eyes to the fact that there are faults, nor would it be right that we should do so; but the composition is one that will be eagerly sought for by all lovers of the picturesque and graceful, and the printing and general manipulation are such as to leave nothing for fault-finding. The "sharpness" and amount of detail do not in any way detract from general breadth of treatment, but on the contrary remove the chief failing to which "breadth" is generally liable, viz., too great an amount of indistinctness and want of finish. One sure test of excellence is exemplified in this production — *it wins upon the beholder by frequent inspection.*

The last to which we shall refer for the present is another subject by the same able artist, and is entitled

"Preparing to Cross the Brook." It is an incident in the day's wanderings of our same three little friends — time high noon. The cool waters of a stream are in the foreground, and more of the brook itself is seen winding away in the distance on the right. The banks are steep and rocky, but their natural ruggedness is softened by the graceful fronds of numerous ferns. The scenery reminds us of some parts of the north of Devonshire.

The central figure, the youngest of the three girls, is seated on the bank at the water's edge, and, having already denuded herself of shoes and stockings, is tucking up her petticoats preparatory to wading across — an operation to which she appears by no means disinclined, the refreshing coolness of the stream being decidedly agreeable in anticipation. On the right, another girl, seated on the ground in a very natural attitude, is in the act of taking off her shoes, whilst on the left, a third is lying down at length on some flat rocks by the water's edge, as if thoroughly wearied out. This however is the weak point in the composition; for although the *pose* is otherwise natural, the head is lower down than the body, and the attitude could not consequently be maintained with any degree of comfort for more than a few minutes at a time. The left hand, and both

feet of the girl to the right side of the group, being in the corner of the composition, are very much enlarged. With these two exceptions, and indeed in spite of them, the whole calls forth a very favourable verdict. The shadows are deep and transparent, the half-tones delicate in the extreme, and, like the subject previously noticed, it is most artistic in treatment.

Artists of every kind, photographers especially, will we are certain accord to Mr. Robinson a well-merited tribute of praise. The printing is most carefully executed, the tone pleasing, and in both cases the grouping is extremely well managed — unity of design being united to variety of *pose*, and the whole extremely well balanced.

It is with considerable regret that we learn the negative of *Nearing Home* has been injured, we fear beyond remedy; but we trust that the hand that executed it has not lost its cunning, and that another edition may take the place of the first.

Both of Mr. Robinson's works have been executed with one of Ross's orthographic lenses, of twenty inches focus, which the former finds to answer his purpose for groups better than the portrait combination.

It is owing to the use of this lens, which covers a large area for its focal length, that the indistinctness of foreground in the first and enlargement of the feet in both pictures are due. The lateral rays do not come to a focus until farther from the lens than the central rays, hence the flatness of field and consequent definition on a flat surface; but as increased distance from the lens implies an *increase in the scale* upon which the delineation is effected, a large angular field of view, coupled with a flat plane of delineation, are incompatible with one another without a sacrifice in some direction. In landscapes, the increase of scale is of but little moment, but for figures it is better not to work the lens so as to strain the amount of field covered. The indistinctness of foreground would be remedied by slightly "cocking" the camera; but this would form no palliation for the enlargement.

We are glad to find that Mr. Robinson employs a camera made by a common carpenter, of pine, which we are assured wears as well as the more expensive articles.

FURTHER MODIFICATION OF THE WAXED-PAPER PROCESS.

By * * * M.D.

Desirous to avail myself of the suggestions appended to the article, entitled "Modification of the Waxed-Paper Process," in your last number, and several solutions at hand being suitable for the purpose, I proceeded on the 1st ult. to prepare some papers, of different kinds, by the suggested, and others by an abbreviated method, using the same materials in both.

You advised procuring an albumenised film to work on; already I had tried some albumenised paper (Marion's positive) and some foreign plain, by first iodising without albumen, then using the paraffine solution, and when dry sensitising, but was disappointed. In the first case the paper became almost black when developing, in the second the paper by transmitted light was spotted and the picture very variable; hence I suspected some difficulty.

Being without bromide of ammonium, the following proportions were mixed: —

Albumen twelve drachms, strong liquor ammoniæ twenty minims, beaten together for five minutes; to which was added, when dissolved, a solution containing iodide of ammonium eight grains, chloride of ammonium two grains, bromide of potassium four grains, clean rain water one drachm, then filtered through double linen. The papers were singly floated on this from four to five minutes, then dried before the fire; here there was some trouble, as the papers set in wrinkles, and the albumen solution tended to run into the hollows. To avoid this, on lifting the papers from the liquid, a glass rod was made to gently follow the draining fluid; the film then seemed to set more evenly. I confess, nevertheless, that in more than one case I found the film somewhat disturbed.

When dry, the papers were immersed singly for five minutes into the following:—

WAXING SOLUTION.

Bees-wax, scraped fine	20 grains.
Paraffine oil	1 ounce.

Put into a bottle, and set in hot water; when the wax was dissolved there were added —

Crushed iodide of ammonium	each 10 grains.
Iodine	
Paraffine oil	1 ounce.

This solution had been made some time previously.

After a little time it becomes dark greenish, and gives a sort of tarry deposit with the solid parts of the wax, and sometimes sets in globules on the inside of the vessel, which when smeared on the finger smell of tar and iodine, and are rather difficult to wipe off; thus it requires to be filtered for use. The papers, when removed were pinned up to dry in the air — the thinnest paper (Canson's) took the longest time. After drying, they were floated on the following:—

SENSITISING SOLUTION,

Which in other experiments had given more regular results than that of formula No. 6 in your Journal of the 1st ult., where I see an error has been made. It should have stood — Nitrate silver forty grains, instead of eleven grains. Thus: —

Bromide of potassium	1 grain.
Nitrate of silver	40 grains.
Distilled water	2 drachms.

Mix.

Then add gradually water ten drachms, Beaufoy's acetic acid four drachms; thus differing from No. 6 in the substitution of bromide for iodide of potassium, with less acetic acid.

All the papers were floated on this, albumenised side downwards. A difficulty presented itself with all but the thinnest — they curled upwards so strongly that they *could not be left* to themselves, but were obliged to be kept down by alternate pressure on the edges: this, perhaps, may be avoided by damping the back; strongly breathing on it did not answer. After floating four to five minutes, they were removed to clean fresh rain water, and floated one minute; removed to blotting paper; pressed; then placed between some clean leaves of the same, and put to dry in a drawer covered by yellow paper.

In the interim I was induced, from some experiments made the previous week (but not alluded to in my former communication), to mix four parts of the albumen solution with six parts of the paraffine solution. They united as an emulsion. Test papers were separately placed on it: Turner's I could not float without soiling the edges, so immersed them; for five minutes longer would have been better. When dried, they were all sensitised as above, by floating one side only, &c. To hurry the drying of one of the first prepared papers it was wrapped in blotting paper, and placed in the breast pocket.

A picture was taken at five p.m., two minutes' exposure; another three minutes' exposure, fair sunlight: the first developed in fifteen minutes, the second in less. The former, with a few lines, was forwarded the same evening for your inspection. One of the papers on the emulsion plan was exposed a little after five o'clock for the same period; and, considering the hurried manner in which the papers had been prepared, I fancied, when on the developing glass, gave promising results, as was stated in the note. Enclosed you have the picture of first plan obtained on three minutes' exposure, and the first by second method, with sundry others. The former gives a good chance of success to the painstaking: the second, though effected by a saving of time, has a faulty-grained appearance. Turner's paper of 1850 has furnished the best proofs.

Several pictures by the first plan were failures from circumstances under control, and now only mentioned to show the care required: such as that placing the warm fingers on the back of the prepared paper, though in contact through a piece of black paper, produced less sensitive spots; some arose also from particles of the edges of the papers having floated on the surface of the albumen solution, and having been drawn across the paper by the glass rod; another by forgetting to wash and wipe the rod after use before applying it to the surface of another paper. The most general failure was from leaving the albumen paper in too short contact with the paraffine solution, or too brief a time on water before development, to remedy which I now prefer to immerse them.

The developing solution was changed to this: —

Pyrogallic acid	6 grains.
Beaufoy's acetic	2 ounces.
Pure rain water	6 ounces.
Alcohol	1 drachm.

and used without any other addition than one drop of a 30-grain solution of nitrate of silver to each drachm. The papers were laid face down on this poured on a level glass plate. Some placed in gallic acid, previously described, gave only a weak picture after two days. I have remarked that the chemical interchange seems to be

completed when the papers are removed from the sensitising solution to water.

To compare with the paraffine process as now described, I hand you some specimens taken on albumenised and non-albumenised paper, prepared with its rival belmontine, with the addition of ten grains of bees-wax to each ounce of the formula noticed in your former number. It gives clean pictures and withstands the developer well; the paper is less stiff. I should have tried pressure but was without a press or mangle.

In applying the developing solution I place the glass plate on the edges of a wide stone glazed pan, by which plan you can manipulate easily. It is right to state that the papers prepared with belmontine *without* wax have not kept well.

With the rest is a failure, a negative taken by Chamblant's (I believe is the name) single cylindrical spectacle lens, given me many years since by that ingenious and successful optician, M. Nachet Fils. When trying this lens, I remarked that objects of a blueish or lavender tone appeared on the ground glass of much deeper tint, and that the picture developed very quickly. In some of the negatives forwarded you will find that the albumen solution has been omitted. The thin hard paper, marked July, 1858, to which you called attention in the previous negative sent, was, I believe, from similar proofs at hand, Marion's thin plain paper treated as stated and re-waxed with a *very hot iron;* they were about the first negatives in which I adopted the quick method of developing.

Permit me now briefly to allude to your courteous remarks on the positive appearance in some of the previous negatives. You say a slight deposit of silver has been formed on the back, &c. This may be the case. By burnishing I could not give a metallic face to the deposit. Why should the daguerreotype semblance be only on the back of the paper? You suggest it had been sensitised both sides; this possibly was the case with those sent, yet I have found it occur when the paper has been sensitised only on one side, or rather when only one side has been treated to all the solutions. Again you suggest slow development; now I found it where the action was rapid or in the quick mode of developing, the slow plan with the same exposure not giving like results. Over-exposure, at least so far as I can judge, appears necessary to so modify the materials, or produce that condition of the organic matter that other substances are known to supply, when added to silver solutions. Still, whatever the cause, we are I believe in doubt for a fair surmise as to its being visible only on the reverse side of the picture. Your indulgence will, I am sure, see in the foregoing remarks only a desire to arrive at a more perfect explanation of a curious appearance, and also I hope excuse the length to which this contribution to your pages has arrived, which, should it lead to any satisfactory results in the hands of your readers, will amply gratify the writer.

[In addition to the remarks upon the above made elsewhere, we have one or two to add here.

The papers prepared with the albumen and other solutions mixed as an emulsion appear to have produced streaky pictures. By far the *best* results (these being *very* good) are where the paper has been albumenised and then treated with paraffine or belmontine oil with wax, &c., as indicated; and of these two the former is in our opinion superior. We consider the process well worth the attention of practical photographers: density and detail, half-tone and sharpness, all find their due place.

With respect to the cylindrical lens mentioned in the paper, our contributor appears to have forgotten that as it is an uncorrected one the chemical focus is nearer to it than the visual one, hence the want of distinctness in the photograph taken by it.

We have several times thought of employing such a lens; but to make it effective it should be mounted with a diaphragm of peculiar construction. We may enter upon the consideration of this in a future number.—Ed.]

EXPERIMENTS IN PARALLEL DIRECTIONS.

It was remarked to us some time ago, that "an editor has need of the hide of a rhinoceros," certainly his equanimity should not be too easily disturbed or he runs a risk of having but a sorry time of it. We have occasionally had to put up with personal observations somewhat of the roughest, but upon the whole we are very fortunate in this respect, for the kind and courteous remarks with which we are not unfrequently favoured outweigh those of the opposite character more than tenfold.

Our present trouble (although *we* are personally involved in grievous charges also) is to keep the peace between our contributors. Who could have supposed that the above innocent heading would have given offence? Yet such appears to be the fact, as will be seen from a letter which follows, and which we have received for publication.

As in that letter many unreasonable charges are made, and in our opinion some unfounded claims to priority are put forth, we purpose replying *seriatim* to the observations; but in order to let the writer have perfectly fair play, we shall give the letter in its "native purity," adding only a few *numerals* as guides to the points against which our replies will be directed.

Lest our readers may regard some of the phrases and epithets employed as rather opprobrious, we may remark that *we* have learned to take them in a "Pickwickian sense," being assured that they proceed rather from energy of character than from malice; and that in matters of opinion, though we may take a very opposite view from that of our correspondent, we have a very high opinion of his chemical acquirements.

We will, therefore, without further preface lay before our readers the letter alluded to, simply remarking, that though bearing date 2nd August, it did not reach us until the 13th of the same month.

Edinburgh, Wednesday, 2nd August, 1859.

Sir,—I have just been looking over yours of August 1st: so far very well. Your critique is not bad; but farther on—(1) As to your "M.D." paper I must, without personal offence, tell you I am getting a little tired of a certain sort of "Parallel Researches." No sooner is my pamphlet out then we have, first, the precipitation of *silver-oxide* parallelised by Mr. Hannaford, and next "M.D." comes out and parallelises, from the same pamphlet, my recommendation of *paraffine* and solution of wax in *benzole,* and the albumen on *waxed*-paper (recommended by me long before, but brought forward again formally in it). A pamphlet of limited space does not permit giving more then the general outline or *principles,* so that *if this system is to go on* it will be easy enough for a set of fellows who never had the *gumption* to *start* a single *new or original* idea to *parallelise* every fraction of it *bit by bit,* and leave me no merit whatever. The suitableness of certain substances being *once* pointed out to the public, I am only delighted to find photographers following my recommendations and favouring the public with their experience as to the *best* proportions, &c. &c.; but it is rather too bad to find them thus *uniformly* ignoring, and *frequently ostentatiously parading* their ignorance of the *original* recommendation whence they are manifestly derived. I could now name some dozen or so of cases in which the same has occurred. Scarcely three weeks generally elapses, sometimes not many more *days after* my publication of a novelty, the result, perhaps, *of much chemical research* and *investigation,* but what it is *parallelised* in this way by some man who, however good a photographer, or however *industrious* a dabbler in experimenting he may be, has never before shown the slightest ability for *finding out* any thing really new for himself. (2.) It is the solid paraffine which is *chiefly* pointed out in my pamphlet: although I have recommended the liquid also strongly I have not been yet able to get it so pure or free from unpleasant smell as to be at all very agreeable to use.

(3.) But in the paper "On albumen, or waxed and similar papers," which I sent you, which ought to have gone in, instead of the miserable little scrap which has gone in, you would find the *liquid* paraffine also *especially* noted under its more proper and especially distinctive cognomen of *rupion.* I do not mean to blame you of course for not putting it in already (as thinking there might possibly not be room for it along with the rest, I especially wished it as "for insertion in the Journal after next"), still, as you have put in the fragment which was only the rough draft of the beginning of it, and never intended for publication in that form, it will now be obviously *essential* that, in publishing the proper formula (which you have) *in the next,* you *prelude* it with an editorial notice that it was sent you and in your hands for publication long before August 1st, and that the "albumen process," by me, in August 1st, was merely the rough scrawl of the commencement, published instead of it by a mistake.

The rough elementary draft was sent up along with the "collodion process," and the *full* and *fair copy* followed with the interval of only one post, *written on a sheet of yellow paper like this,* and with the ratification which I have quoted above at the head of it.

I *must not* have it *lost* or *omitted* in your next.

(4.) I am disappointed to see that even the errata, corrected and necessary emendation made on the said rough scrawl, *when the proof of it was sent down,* have not been attended to; *e.g.,* the pyrophosphate being given in grains and the phosphates in atoms, which looks very absurd.

However, the correct copy in the next Journal, coupled with your editorial notice of what it is, and *when* it was received, will put this to rights.

(5.) You have not noticed or acknowledged in any way, the platinum-toned specimen I sent. It cannot have miscarried.—Yours, &c. C. J. B.

P.S.—I am much amused at the guarded way in which, while probably quite ignorant of them, "M.D." *cautiously* keeps a loophole open for the *after*-discovery of "chemical considerations," in case, I suppose, I should point them out for him, as I dare say he has a *guess* that chemical reasons *there*, as well as elsewhere, generally are at the bottom of my recommendations, as they most assuredly are.

I am the last one to grudge any one the credit rightly due to formula making or settling of best proportions; but what *I do* object to is the first trier of any new process not being content with this, but *uniformly* and, without exception, attempting on the strength of what he has, or possibly enough has *not*, settled, by some dozen or half-dozen of experiments, taking the credit for also what he has not given as the slightest reason for believing that, if granted a Methusalean longevity, he would ever have expiscated from his own cerebral organs.

You have, in your leading article, most forcibly drawn attention to the absurdity of our prize offerers classing the mere producer of a picture, or successful *worker* of a process, in a grade of higher merit than the discoverer of the process by which it is produced. On the same grounds these attempts of *mere* formula-compilers to monopolise the merit of everything new are equally preposterous; indeed, they show *their own* consciousness of the *inferior merit* alone which their experiments can *rightly* claim by their uniform attempt to claim *also*, and at the same time, the merit due to others. I dont depreciate their merit when they have had any *real* difficulty or obstacle in manipulation to overcome in bringing the suggestions of the originator into practice, or reducing them to an available form, for the public use. Neither I nor any rational discoverer will *grudge* them this. *Too* often, however, the application is perfectly simple, and all *plain sailing*, so that they see well enough their *proper* share of credit would not satisfy their appetite. Hence their *uniform* ignoring of that has been published one, two, or three weeks before, *as a matter of course in some Journal which they never see*, or pamphlet which they have *not* read.

After my *former* explanations as to yourself, you must of course not *again misunderstand* my criticism of what you only want to see to disapprove.

The honest course would be simply for the *improvers* or *adopters* to state formally *what difficulties* they *found* in any process *as given* by the originator, *and how* they have overcome or remedied them, and then let them leave it to the public to give them their *fair share* of merit *in proportion* to the original imperfection and difficulties of the process as given, and *the amount of labour and* INGENUITY NECESSARY to vanquish them. This *fair* share of merit, in proportion to the real *head work* involved, I should be the last to grudge. The system I do complain of, however, is on the other hand, far worse than even that prize—"lollypop"—system which you so forcibly cut up in your *leader*, inasmuch as no one is obliged or can be obliged to subject himself to its operation; while *here*, again, there is no choice, and you are "*paralleled*" at once without leave asked or given.

Fomula making, properly conducted, might, though often hardly necessary (and most highly appreciated by those who require *spoon-meat*), might still be *often* useful and *convenient*, as well as meritorious, *in proportion* to *real* difficulties *surmounted*; but *this* systematic *parallelising* bids fair to be the *paralysing* of all real discovery, as no one is likely to *continue* his researches, *or at all events* to give *them* FREELY *to the public*, when *sure* to be *paralleled* in this way, within two or three months, weeks, or days. I know that you have only to look at the matter to see as I do, that this is going *rather too* far.—In great haste, yours truly,

C. J. BURNETT.

The perusal of the preceding fairly takes away one's breath, and it is really difficult to know where to begin in reply; but we will make the attempt.

1. As regards Mr. Hannaford, we have already expressed an opinion—that opinion we see no reason to change.

With reference to the papers of * * * M.D., which appeared in our number of the 1st ultimo and in the present one, we have to make two assertions, which take them out of the category in which Mr. Burnett has placed them.

First, we have *specimens before us* (and had them when we published the paper) that were produced in July, 1858, ten months prior to the publication of the pamphlet.

Second, they are *not* copies of any suggestions in the pamphlet, which consists, by the way, of sixteen octavo pages, and though applying to negative processes upon paper, is very similar in style and principle to Mr. Burnett's paper "On Positive Printing Formulæ," which has already appeared in our columns. As the pamphlet is anything but *light* reading, we do not expect that the circulation is very extensive, and therefore one can easily conceive that there are many photographers who have never even heard of it, much less read it.

We have carefully looked through the copy last sent us by the author as complete, and all we can find in reference to the subject is the following, pages 8 and 9, which we extract, viz.:—

C.

"[*a*] In the case of papers prepared with simple solutions of cereoline in alcohol, or wax in turpentine, naphtha, or benzole, or gutta-percha in benzole or benzine, to be iodised afterwards, the salting, &c. by the baths already mentioned presents no peculiarities of any great importance.

"[*b*] And the same applies to papers prepared with solutions of paraffine, palmitine, or a weak solution of gum-lac and other resins in alcohol, either along with or without wax, on which I have made some experiments.

"[*c*] But the most convenient plan with these papers is of course the introduction of the iodides, &c. into the solutions we have mentioned in [*a*] and [*b*]. Many of the organic salts recommended by me are insoluble in alcohol, but others are more or less soluble, as some of the formiates and benzoates, and the succinates of soda and potash. The chloride of cadmium is also soluble in alcohol, and might thus be used with the bromides and iodides, with or without the organic salt of cadmium."

D.

"Films of albumen on plain paper or on wax-paper, or paper prepared with solution of gum-lac or other resin in alcohol, or of gutta-percha, india-rubber, gum-dammar, or copal, in turpentine, naphtha, benzole, or benzine, may be salted with the same mixtures of iodides, &c., with organic salts, or of iodides, &c., without the organic salts. The cadmic salts, from their coagulating albumen, cannot well be introduced into its solution, but can be introduced by preparing first with simple albumen, or its solution, and afterwards floating the albumenised surface on the solution of the mixed cadmic salts."

2. It will be observed from the preceding that it is solid paraffine dissolved in alcohol, turpentine, naphtha, or benzole that is spoken of, and we can hardly regard so obvious a variation on what is already practised as a new suggestion—with the exception of the introduction of the iodides, &c. in these solvents. Now * * * M.D.'s paper was prepared with a fluid, oily substance, of a red color, more or less volatile, extracted from peat, and known as *paraffine oil*, a cheap and easily procurable substance very different from the solution of paraffine in alcohol, &c., it being in this oily substance that the salts quoted HAVE BEEN PROVED by * * * M.D. to be soluble, a fact that could not have been suspected *primâ facie*. This, be it observed, is not a mere hint that such a proceeding may do, but an accomplished fact *proved by the production of many good negatives*.

3. The section of the letter which we have indicated by this number is so startling that we shall reply by an anecdote, for the truth of which we can vouch:—A neighbour of our own was frequently annoyed by an old lady, neither too slim nor too scantily clad, who would persist in occupying a seat in his pew contrary to his wish, and to the consequent exclusion of one member of his family, and the material discomfort of the rest. Several appeals to the pew opener being found useless, our friend tried the clergyman, who, of course, replied that such a nuisance should be put a stop to, and inquired who it was that was so persevering? On being told, his countenance fell, and he said, "I am afraid it is a hopeless case, for Mrs. —— is that sort of woman, *that if she chose to occupy the pulpit, I should have to preach from the reading-desk!*"

It is perhaps needless for us to say more than that we are *not* so complaisant as our clerical friend.

Our correspondent is in the habit of writing to us much that is intended for publication, and still more that is not, all mixed up together, so as frequently to render it impossible to separate the two; much is often repeated in various forms, and *all without exception* written in a style that he himself has most properly designated as κακογραφια, and which is rarely readable except with the penalty of a splitting headache. Moreover, he appears entirely oblivious

of the fact that from Edinburgh to London is a day-and-a-half by post, while from London to Liverpool takes another day, and we may just insinuate that we are not always at hand precisely when the letters arrive, nor always at liberty immediately to deal with them. How is it possible for us to know when a complete copy is to come by the next post unless it be intimated in the first, and if it be, more often than not it does *not* come. Besides, many notes bear no date at all, some only the day of the week, and when they do bear the day of the month, as in the present instance, the letter is frequently not posted until many days afterwards.

4. The errata complained of are due *entirely* to our correspondent, his corrections (!) were so unreasonable and arrived so late that it was just *impossible* to attend to them.

5. If Mr. Burnett will refer to page 194, he will perceive that we did notice the specimen sent in the very first "Answer to Correspondents."

The somewhat extensive postscript being to the same tune as the body of the letter, does not need any special remark. We cannot, however, conclude without stating again that while we *highly appreciate Mr. Burnett's chemical talent*, and believe him to be perfectly sincere, we do think *that he errs greatly in judgment* in supposing that because he somewhere, at some time, has said, that this substance *may* be used, or that one *deserves* a trial — that he is thenceforth to be considered as the originator of all that may be practically successfully carried out by others in connection with those named substances; and still more does he err in imputing so generally as his words imply the base actions which he indicates.

That Mr. Burnett has suffered from gross plagiarism in some cases we are ready to admit; we have fought his battle when we have thought him wronged; we hold him in high esteem; but we we will oppose him when we think he wrongs others, though in so doing we do not charge him with more than taking a jaundiced view of things, and we are convinced that he mistakes his photographic brethren generally, as much as he is mistaken by them, and that is not a little. If they were only more thrown together perhaps all would find out and exclaim, that we are "Not so bad as we seem!"

ON M. NIEPCE DE SAINT VICTOR'S RESEARCHES ON LIGHT.

By M. L'Abbé Laborde.

In repeating the experiments of M. Nièpce on the persistent activity of light, I remarked, from the first essay, a characteristic difference between the effect produced by solarised paper and that resulting from the direct action of light.

When sensitised paper is exposed for a few moments only to the direct action of light the colour it assumes is wholly external or superficial, and disappears entirely if the surface is lightly scratched. But if the paper is submitted a longer time to the action of light, until it acquires a colour nearly equal in intensity, this colour is not merely external, but it penetrates the entire thickness of the paper, and appears on both sides: we perceive that the sensitised paper has been impregnated rather than impressed, and we are led to admit an emanation rather than a radiation on the part of the sensitised paper. The following experiments leave no doubt on this point:—

To avoid useless repetition, it may at once be stated, that in all these experiments a piece of thin cardboard, impregnated with tartaric acid, was exposed to the sun's rays for about four hours, and afterwards placed in a tin box, to the shape of which the paper adapted itself. The size of the box was seven inches by three.

The sensitised paper, prepared as for ordinary positives, was applied upon a disc of glass fixed in the inside of the cover of the box, and always occupied the lower part.

The action of the solarised cardboard was continued from twelve to fifteen hours. A plate of glass—although transparent—protected the sensitised paper; but it required to be carefully cleaned: without this precaution, the sensitised paper blackens as much, or even more, under the glass than upon the parts exposed directly to the action of the solarised paper.

First Experiment.—The sensitised paper being partially covered by a plate of glass, a second was placed across the first, so that the sensitised paper was separated by a distance of 0.118 of an inch; this second plate, of 0.393 of an inch in thickness, was thus exposed to radiation but not to circulation. When the box was opened the paper was found blackened all over, except under the band of glass in contact with it. But if this first glass band is very thin, so that the distance between the second band and the sensitised paper is very small, the circulation becomes more difficult, and the subjacent paper is partially preserved. In substituting a plate of ivory for the second glass, no difference in the result is observable. This second experiment was made because it has been stated that solarised paper can act through transparent bodies, when the air is frequently renewed, as is shown by certain impressionable substances, like bitumen of Judea, being insensible to light when entirely deprived of contact with air.

Second Experiment.—The box containing the solarised cardboard was left for four hours in a warm place; it was opened cautiously, keeping the opening downwards, and the cardboard gently withdrawn: a sensitised paper, with a slip of glass across it, was promptly fixed to the bottom of the box, and the box closed. It was then put in a cool place, and when opened—after the lapse of twelve hours—the uncovered portion of the sensitised paper was found blackened, notwithstanding the absence of the solarised cardboard. It is evident from these two experiments that the effect is due to emanation and not to radiation.

The question is—What is the nature of the substance that escapes from the solarised cardboard, and acts upon the sensitised paper? The following facts prove that it is a volatile acid, very probably formic acid:—

1st. Blue litmus paper, partially covered by a plate of glass, and exposed to the action of the solarised cardboard, always reddened upon the uncovered portion. This experiment was very frequently repeated, because it could, without inconvenience, be added to all the other experiments.

2nd. In order to prove that this volatile acid was itself the active substance—for it might only accompany it—a large glass tube was enveloped in bibulous paper, moistened with a solution of potass: it was fixed at the bottom of the box inside, and occupied the whole vertical height; a solarised piece of cardboard was introduced; and after putting, as usual, on the interior of the the cover a piece of sensitised paper, and a piece of blue litmus paper, traversed by a piece of glass, the box was closed. At the expiration of twelve hours the litmus paper and the sensitised paper were not altered in appearance: in the absence of the volatile acid, neutralised by the potass, no action was manifested.

To determine accurately the nature of this acid, it was necessary to collect a notable quantity of it. Recourse was had to other means, the result of which renders the existence of formic acid very probable.

1st. Some distilled water was put into a clear porcelain capsule, and exposed for fifteen hours to the action of solarised paper. Some drops of nitrate of silver were next added, and the whole heated to boiling: the liquid speedily became black, as happens when the experiment is made with a *minimum* quantity of formic acid.

2nd. The distilled water was replaced by a solution of acetate of lead; and after being submitted to the action of the solarised cardboard for two days, there was found on the surface of the liquid a multitude of little white spots, which were removed on a piece of paper. They were then boiled with a weak solution of nitrate of silver, which was reduced to the metallic state, as if acted upon directly by formiate of lead. It might be urged that some particles of tartaric acid had fallen upon the acetate of lead from the solarised paper, and formed white spots of tartrate of lead; but to this it may be replied, that lead does not reduce the salts of silver as the formiate does.

3rd. In smelling the interior of the box at the moment of opening it, the mixed odour of caramel and formic acid may be recognised. The presence of formic acid is easily explained, when we consider the influences to which the paper impregnated with tartaric acid is submitted.

Finally, the action of light may be manifested by two opposite effects—reduction or oxidation. The direct effect is always a reduction; it manifests itself upon the salts of silver and gold, &c. To these must be added that which surpasses all the others by its energy and its consequences—the reduction of carbonic acid in the leaves of plants. But reduction supposes the separation of oxygen, or of any other electronegative element—a separation which puts it in a nascent state, and renders it peculiarly apt for uniting with the substances with which it is in contact. If the oxydised body—by its nature and properties—become more apparent and palpable in some degree than the substance reduced, the oxydation appears then solely the effect of light; but it is a secondary effect, such as may be remarked in bitumen of Judea, essence of turpentine, linseed oil, &c.; and, we may add, upon tartaric acid, if we prefer to admit that—under the influence of light—the oxygen tends to separate from the organic matter impregnated with the tartaric acid; for this oxygen, in its nascent state, unites with the tartaric acid, and produces formic acid. The affinity of tartaric acid for oxygen aids this transformation; it is only neces-

sary to add peroxide of lead to a strong solution of tartaric acid to obtain immediately an emanation of formic acid. We may avail ourselves of the property possessed by tartaric acid of readily becoming super-oxydised, and exhaling formic acid, to control the preceding effects by the following experiment:—Put into a test tube a concentrated solution of tartaric acid, and of peroxide of lead; then apply upon the cork a piece of sensitised paper and a piece of blue litmus paper, held together by a band of glass; the cork being fixed in the tube, above the solution, it is placed in the dark, and after a very short time the sensitised paper becomes brown, and the blue litmus becomes red, as if they had been exposed for twelve or fifteen hours to the action of solarised cardboard. Moreover, a new feature of resemblance is, that in either case the blue litmus papers reddened by the acid, left to themselves, gradually acquire their original blue colour.

The facts here given scarcely admit of our admitting the persistent activity of light, and still less of a stored-up light; but if the experiment of M. Nièpce, thus explained, loses its novelty, it retains the stamp of originality which characterises all the researches of its author.

Messrs. Bouillon and Sauvage had already concluded from their researches that the reduction of sensitised paper, submitted to the action of a solarised tube, was due neither to heat nor to stored-up light. The single experiment they quote in proof of their assertion may leave some doubt on the mind, as M. Nièpce had made it himself, and previously refuted the conclusions they sought to draw from it, in stating that the luminous radiations emitted by phosphorus slowly burning in the air do not act through glass. Messrs. Bouillon and Sauvage attribute the reduction of the sensitised paper to a peculiar volatile body, probably ozone; but ozone, far from being a reducing agent, is a powerful oxydizing body. Still we may attribute another—indirect and decisive part—and quite similar to that I have attributed to the oxygen separated by light, in the nascent state, from the organic matter; for ozone is only oxygen brought to, or conserved in, the nascent state, and thus susceptible of oxydising most bodies; and as almost all organic substances, as gum, sugar, starch, lignine, tartaric acid, &c., produce formic acid, with a mixture capable of oxydising them, we see the part that ozone or nascent oxygen can play—not only in this first experiment of M. Nièpce, but also whenever organic matters are exposed to light.—*Le Bulletin de la Sociétié Photographique.*

CULLINGS FROM "THE PHOTOGRAPHER"

M.S. Journal.

Mr. Taylor's Paper.

By private letter each of you by this time is made aware of the cause of the stoppage of *The Photographer's* circulation for such a long time—how that my premises were broken into, and that the dear little Journal was, among other papers, villanously kidnapped. In future I hope we shall go on as harmoniously as heretofore.

Having left Dumfries in favour of Edinburgh—where I trust I am now permanently resident—I will, if not in this, at least in subsequent papers, do what in my power lies to enlighten you as to the progress of photography in these northern regions. I may as well enter on this topic at once, by stating that we have a Photographic Society here, which adopts for its name the somewhat sonorous one of "The Photographic Society of *Scotland*;" probably because *Edinburgh* is the capital of Scotland. I wonder how our Glasgow brethren relish this title? Not very well, I suppose; for, if I mistake not, theirs was the first society—at least in a chronological point of view; but, be that as it may, *we* are now the Photographic Society of Scotland. On the inner life of this society my next paper will treat. My present will be, at least in part, devoted to giving those of you who are interested in that sort of thing, an account of a trial of landscape lenses which came off some time ago, under the auspices of this Society.

A Committee was appointed for testing and reporting on the merits of the various landscape lenses now in the market. If any of you want to see the *official* report, I must refer you to the next number of the London Journal, which is the organ of our Society, and to which I have sent it. That Committee was composed of four members, viz.—Mr. Raven, a capital waxed-paper manipulator, and one of the successful candidates for medal honours at our last examination; Mr. James Bryson, one of our most intelligent opticians; Mr. Tunny, a shrewd and skilful professional photographer, who does a roaring trade in collodion calotyping, of which he was the first practitioner in this part of her Majesty's dominions; and, lastly, myself—your very humble servant—of whom but little can be said, either "good, bad, or indifferent." Well, having got hold of all the Voigtlanders, Rosses, Goddards, Grubbs, &c., we could lay hold of, we proceeded to test them—not so much to establish the superiority of one maker over another, as to see what *class* of lens was best. We had a real tough job of it, and no mistake! The subject on which we practised was a straight row of houses (Montague-street)—in front of which, and at a distance of a few hundred feet, we planted our cameras. The first trial was with Petzval's new landscape combination, as made by various makers of eminence, both at home and abroad. Of these we got the best we could think; but, alas! when we applied the rule and compasses to the finished proofs, all were more or less deficient. Goddard's Petzval gave admirable definition all over the plate (12 × 10), leaving in this respect nothing to be desired; Ross's orthographic (we had two of them) were scarcely inferior in defining power; Voigtlander's orthoscopic gave one of those soft pictures which would have pleased Sir William Newton; but *not one of them* would give absolutely straight marginal lines—they were all curved outwards. We tested Grubb's aplanatic lens, along with another ordinary achromatic view lens of the same diameter and focus. The results were very similar, but Grubb's lens possesses the advantage of working with a large stop, which must render it a good lens for groups or instantaneous views. As was expected, neither it nor the ordinary view lens tried along with it (which was made by Ross) gave straight marginal lines; but in this case, unlike that of the Petzval family, the curvature was inward. The focal length of all the lenses tried was nearly the same, but the Grubb and Ross *meniscus lenses embraced a greater angle of view than the Petzval form.*

Despairing of ever seeing *straight* lines, we next tried one of another kind, and of which we could only procure one. It was one made by Goddard, on the principle laid down by our co-member Mr. Sutton in a recent communication to the London Journal. Well, from one or two simple experiments which I had made, after reading Mr. Sutton's paper, I thought that if Mr. Goddard had done justice to it, the "Sutton" lens was the one which must win the day—at least so far as freedom from distortion was concerned. The result proved my surmises to be correct. Of all the lenses we have tried "Sutton's triplet," as made by Goddard, was the only one which rendered the marginal lines straight. It was a pleasure to look on the proof taken by it, compared with those by the Petzval and meniscus class. All of them defined well—this *only* gave freedom from distortion.

(To be continued.)

NOTES OF A PHOTOGRAPHIC TOUR IN THE HOLY LAND.

No. IV.

I verily believe that the gloomiest spot on earth is the valley of Jehosophat in a rain-storm: and here I must be a prisoner in my tent all day long, listening to the howling of the wind rushing furiously between the Mount of Olives and the hill Moriah, as if the fiends were driving the souls of the damned through the valley—as saith Mohammedan tradition they will one day, when the Prophet shall have judged them on the Temple mound above;—and then, when all is still, solemn, silent, and calm in the valley, I can hear, far up, over the walls of the Temple, the moan of the storm, like the voice of offended Nature, solemnly declaring the vengeance of its God. The swollen stream of the Kedron rushes by yellow with clay. I am seated on a camp-stool, my canvas pinned closely down around the earth heaped over the edges to keep out the streams that come dashing down the Mount of Olives; my shivering Arabs are crouched under the canvas of the servant's tent, and ———

I was interrupted by the irruption of one of the streams I spoke of, which found its way under the edge of the tent, and threatened to carry us away, bag and baggage, but which my men successfully directed into its proper channel again, so that all is once more dry, snug, and close. A tent like mine, in such a tempest as now prevails, is not to be laughed at, let me tell you; and as photographic operations must be suspended for this day at least, I shall devote myself to writing to all friends at home who take any interest in my proceedings, and communicate to you my adventures during the past week.

I have hovered about Jerusalem in every direction, but not yet set my foot in it. I approach it with a vague awe, for I feel that, being holy ground, I must not lightly profane it. I desire to render myself worthy of the privilege of entering the sacred precincts, and

seek to subdue my thoughts and feelings to the true devotional pitch. Therefore, I shall first finish all business requirements, and when my mind is free from worldly cares, put off my shoes, and glide through the city gates, the greatest of sinners.

But every inch of ground about me is holy ground. The Mount of Olives, Bethany, the Wilderness of Engeddi, and many other places familiar to you which I need not name, have engaged my attention. I have been over the hill to Bethany half-a-dozen times already. Often in the morning, rising early, and taking my coffee hot from the hands of my faithful Hassan, I climb the Mount of Olives, and walk swiftly along the winding ridge, down to the old home of Martha and Mary and Lazarus, seeing the sun rise lovingly over it, and then return to breakfast and a day's photographing.

Bethany lies but a short walk from Jerusalem — perhaps two miles—on the eastern slope of the hills which are called the Mount of Olives. This road is the saddest and holiest walk on this earth. How often trodden by those weary feet that bore our heavy load! Morning and evening, going out and coming in to the city, He passed this way. On it He bade the fig-tree wither: on it He mounted the asses' colt, for His only triumphal march on earth. At the one extremity of it was the home of Mary and Martha and the tomb of Lazarus; at the other, the Cross and the Tomb; and somewhere along it is the dust He shook from His feet on the earth that had rejected Him as He ascended to His throne. Sad and sublime path from Jerusalem to Bethany! Above it angels hover for ever, worshipping the tears that dropped all along it from the sad eyes of the Man of Sorrows.

The old village lies in ruins. A deep dark vault on the side of the hill, into which you descend by a flight of stone steps, does duty as the tomb of Lazarus. I know no reason to doubt its correctness; some such place here he occupied, and perhaps he slept in this again after his Saviour was gone whither he followed Him. I sat down on the ground in a shady lane or road that runs down to the hill-side, in the edge of which is the tomb; and here, as a thousand travellers have done, read over again in the Bible the beautiful story of the brother of Mary and Martha.

The day wore on, noon came and past unheeded, the sun went westward, and still I lingered. Could you but have seen how sadly splendid was Jerusalem in the sight of the setting sun, as I returned to my tent over Olivet!

I set off alone the other day for the Wilderness of Engeddi and the Convent of Saint Saba. It was a delightful day for the road. All down the bed of the Kedron it was fresh and grand; wild flowers starring out on us everywhere. All over the hills of Palestine there are to be found splendid varieties of the anemone.

Following the Kedron down some ten or twelve miles to the south-east, I reached a spot where it suddenly began to descend rapidly between lofty and precipitous sides. Instead of descending with it, I found a road cut in the cliff on the south side of the ravine, along which I rode, while the stream continued to descend deeper and deeper, the gorge growing more dark, profound, and magnificent, until it became several hundred feet deep—I will not attempt to guess how many, but not less than four hundred I think it safe to say; the sides abrupt, bare rock, nearly perpendicular, the top only a gun-shot across. And now I knew I was in the Wilderness of Engeddi, which has been famed in all ages.

My mare snuffed the desert atmosphere, and tossed her head into the air with the utmost delight. The odours of the city had not been agreeable to her, and she had been stabled night after night in the vacant tomb of a wealthy Jew of the olden time, in the Valley of Tombs.

Hassan met some of his old friends as we entered the gorge. There was an Arab of the Jordan Ghor—a sheik with two or three followers — who eyed us suspiciously as we approached; for I had not seen fit to make any arrangements, or pay any tribute to his tribe for protection. Hassan recognised our present friend as a notorious camel-thief, to whom he owed somewhat — as Arabs owe debts to Arabs — in the way of revenge.

A guttural grunt, not unlike that of a North American Indian, was the only salutation as they passed each other, and when the chief came to me, lounging along a dozen rods behind Hassan, he paid no attention whatever to my "*Salaam Aleikoum*," whereby I knew him for an enemy. It mattered little, however, for one Frank is fully equal to four Bedouins, and there were no more of them, and I had two six-shot revolvers in my holsters. But it behoved me to keep a sharp look out on my way back to Jerusalem. More than once in my rambles a bullet has whistled past my ears, without my being able to discover the miscreant who fired it.

A little further on we came to a point where the left or ravine side of the road was closed up by a stout wall, extending along the ridge, descending into its depressions, and flanked by two high stone towers. This is the top of the Convent of Saint Saba, which hangs on the precipice from its summit two-thirds of the way down the ravine, and there impends over the abyss below. D· T.

Practical Instructions on Coloring Photographs.

By Alfred H. Wall.

CHAPTER IV.

MAXIMS *(continued)*.

54. "To produce force, solidity, and strength, some part of the picture should be as light and some as dark as possible; and these two extremes must be harmonised or reconciled to each other by a proper introduction of gradatory tints and demi-tints."

55. "Truth of colouring consists, not in giving to objects their precise local colour, but in so contriving that they shall seem to have it."

56. Broken colours in the background give value to the purer colours of the flesh.

57. "Simplicity and keeping are the basis of purity and harmony."—*Fuseli.*

58. A pale subject may receive warmth, a red or brown one pallor from the colours of your background.

59. Backgrounds give excellent opportunities, not only for distributing colour to produce effects of harmony or contrast, but also in extending or concealing form, &c.

60. "Strong colour requires deep shadow to support it."—*Burnet.*

61. "Variety of tints, very nearly of the same tone, employed in the same figure, and often upon the same part, with moderation, contribute to harmony."—*De Piles.*

62. "In a single head we often have but one light; it is therefore necessary to get it to harmonise with the shadow in the background or upon the dress. Rembrandt, accordingly, frequently painted the light of the dress the same colour as the shadow side of the face, thereby keeping up a union and simplicity."—*Burnet.*

63. "Colour holds the station of middle tint. * * * * The proper situation of strong colour is neither in the high light nor in the deep shade, for it would destroy the character of either; but if it is made use of as an intermediate link, it will unite both.—*Ibid.*

64. "No object, of whatever kind it be, were it executed with the greatest perfection, will ever pass for being a 'good choice,' if, by the unskilfulness of the painter, it be placed upon a ground of one single monotonous tint."—*Francois-Xavier de Burtin.*

65. Every tint and shade should be subservient to some one general tone of colour previously determined on as most in harmony with the subject, its sentiment, or effect, as Fielding says — "In every harmonious composition of colours there is a principal tone, key, or predominant colour to which its other hues refer subordinately, as in music."

66. To prevent any appearance of the figure being "*inlaid*," Sir Joshua Reynolds says — "The ground must partake of the colour of the figure, or contain such a mixture as to exhibit in it something of every colour in the palette."

67. "When a form is beautiful, it ought to be shown distinctly; but when, on the contrary, it is uncouth in shape or hue, it may be lost in the background. Sometimes a light is introduced, to join and extend the light on the figure, and the dark side of the figure is lost in a still darker background; for the fewer the outlines which cut against the ground, the richer will be the effect; as the contrary produces what is called the *dry manner*."—*Sir J. Reynolds.*

68. "By mellowing skill thy ground at distance cast,
Free as the air, and transient as its blast;
There all thy liquid colours sweetly blend,
There all the treasures of thy palette bend,
And every form retiring to that ground
Of hue congenial to itself compound."—*Fresnoy.*

69. If objects are introduced into the background they should be few in number, and should be kept subservient to the figure. Landscape backgrounds should consist of broad features and few details, and should be kept low in tone. The introduction of a few warm tints into the sky near the horizon serves to repeat the colour of the flesh. The horizontal line should not be placed too low."—*Mrs. Merrifield.*

70. Distance is obtained by diminishing the intensity of *colours.*

71. Powerful contrasts should be avoided in parts requiring *quiet* and retiring qualities.

72. "There may be the most perfect combination of beautiful colouring, which, if inappropriately applied, would not only fail to

produce a pleasing effect, but would destroy the whole harmony or truthfulness of the picture.—*Wyke Bayliss.*

73. "It is the background which forms *the picture*, and its use is *not merely to throw out the principal object*, but by its tone and colour to control and harmonise the whole."—*C. W. Day.*

74. "When the flesh colour of your sitter is a very bad one, you will find that a background of dull green will give it its full value—that is, it will, by contrast, show the reds to the best advantage."* —*Ibid.*

75. "A good background never obstrudes itself on the eye or observation, but in all cases is subservient to the effect of the portrait or figures; therefore a background should be simple, broad, and in all cases partaking of an atmospheric tone, neutral and retiring, but not cold."—*J. S. Templeton.*

ON DRAPERY.

Graceful lines, harmonious colouring, contrast and relief, may be helped materially by your treatment of drapery—with, however, especial reference to the colour and character of your flesh.

Folds in the photograph are—by mere chance, perhaps—very frequently too numerous for breadth of effect, or too ungraceful; judicious alterations are therefore permissible.

These precepts may be looked upon as so many direction posts, put up by great travellers who have passed over the tract you are about to trace; and have thereby reached the goal you, I presume, are anxious to attain. Their use will be appreciated best by those who, having taken wrong roads, have recovered the direct path by their aid, and least by those who would rather trust to their own inexperience (or ignorance) than *condescend, or take the trouble* to receive tuition from another's wisdom. It were very little use to supply the means of travelling if there were no roads, and roads themselves may confuse and delay if they are not provided with *direction posts.* Just so with these articles on colouring: it were but little service to my readers if I told them how to use brushes, or mix and apply colours, if I left them ignorant of such principles as develop the end and aim of all true art, viz.—*the perfect representation of nature.*

The simplest and easiest style of colouring is that applied to glass positives and daguerreotypes. To this, therefore, I shall first direct attention in the next chapter.

* Or (of course) where the flesh of your picture is coloured badly, this background will also assist you.

Letters to a Young Photographer.

No. XVIII.

MY DEAR EUSEBIUS,

I shall bid adieu to processes for awhile, quit the mechanical and take up the poetical side of our art: enter the domain of æsthetics and endeavour to initiate you into the occult doctrines of the Beautiful. I shall not add to the melancholy list of limping philosophers who, from Plato downwards, have essayed to define Beauty; let it suffice to you that it is indefinable. Doubtless most of us feel it, and if we do let us be thankful, and not profane the feeling by seeking to clothe it in words. But the faculty of perceiving the Beautiful in Nature and in Art is not enjoyed by every one, least of all by many who call themselves artists; they are mostly slaves of convention, which in their blindness they think is Art, worshipping a false idol for the true divinity—heathens who abandon the goddess Nature for their golden calf—Art.

The faculty for Art—the perception of the Beautiful—the "play or sportive impulse" appears to be a sixth sense, possessing a bump or organ of its own, not mapped down by phrenologists. Perhaps it has no external organ like the eye or ear, hence the difficulty of demonstrating it. Concealed *within* the brain it is invisible; but from its mysterious retreat it governs the other five senses, and renders them subservient to its purpose. With our eyes we see, with our ears we hear, with our nose we smell. But what is it we see, hear, and smell? To the brute creation also the leaf is green, the sky resplendent, the flower fragrant: they derive these perceptions through their five senses, but nothing beyond, for want of the sixth.

In man alone this sixth sense is found. The rudiment or germ of it is doubtless in every human being; only in some it is developed, while in others it for ever remains dormant, abortive, or perverted.

Unfortunately no name has been bestowed upon this art-faculty. By some it is styled "poetic temperament." Of a certain person it is said—"He has a poetic mind, or a poetic nature," while those prosy persons who study to be facetious, call it "the bump or organ of the Fine Arts."

Now in those who possess this organ, whatever it be, there is a something which is responsive to what we regard as the Beautiful, which was so keenly felt and enjoyed by the ancient Greeks. It is akin to what is called an ear for music, an eye for colour. For it is well known that many persons cannot distinguish one tune or one colour from another, yet they do not appear to be deficient in any organ. They have eyes, but see not; they have ears, but hear not. What then does this sixth sense see or feel? It sees, it hears, it tastes, it feels, it smells, in a word, it combines the functions of the other five, but only in an ideal world, wherein the other five do not, cannot enter. From the leaf, the flower, the sky, the stream, it enjoys a charm which belongs neither to blue nor to green, nor to brilliancy, a charm of which these perceptions are the occasion, but not the object which excites and stimulates them, but which cannot of themselves produce it. We may assert that this charm exists, but how can we depict it? When we endeavour to reach it it fades away; when we endeavour to seize upon it, it eludes our grasp; when we endeavour to fix it, it disappears.

This charm consists in feeling in the leaf something of its lightness, its decay, its ephemeral existence; it is to dream, in connection with it, of the rapid flight of time and of the sad metamorphoses effected by it. It is to recognise that our destiny is the sport of external things, as the leaf is the sport of the winds. It is to feel in the stream something of the peaceful and the lovely; a pure reflection of the sky, or a mysterious retreat, variable as the clouds above it, leading the mind either to a melancholy that gently affects it, or to a calmer joy that soothes and refreshes it. In a word, it is the "faculty divine" of the poet.

Whatever it be, this organ is the progenitor of the Fine Arts, acting through man's impulse to reproduction; exciting the creative instinct. It is this creative power that renders the pursuit of Art so fascinating. If the features of a landscape, its rocks, trees, clouds, and their reflection on the bosom of a calm lake, strike this sixth sense, so as to excite the charm I have spoken of, we are immediately seised with a desire to reproduce this image.

This desire proceeds from imitation, being a pleasure natural to man which delights to see the resemblance of something grow beneath his hands. But yet it is more than this, for with man, to imitate is to create; it is the gratification of our self-love that allures us; it is an exercise of power that exalts us; it is the noblest exercise of our faculties.

Again, this peculiar sense is also necessary to enable persons to enjoy the productions of art—the master-pieces of the great artists of bygone times. This poetry of the mind, which in the fine arts applies itself more particularly to the work of imitation, may, independently of all imitation, be extended to everything, and embrace whatever the human mind can conceive. There is poetry in the history of the past—a poetry that hovers and soars around and above the facts of which it is composed. There is poetry in man's life, in the play of his passions, in his vicissitudes, in his mysterious destiny, in virtue, in sorrow, and even in crime. Above these things, considered as facts of human existence, there is a pure and calm region to which our thoughts retire, to enjoy the emotions they give rise to, and of which these facts are to the soul what the leaf is to the eyes, the occasion rather than the object.

From poetry proceeds noble thoughts, generous impulses of the heart. In the Arts it loves the beautiful, it seeks it and reproduces it. To every vivid feeling is allied the desire of expressing it, of representing it to one's self and to others. To enjoy the beauties of nature alone is only to half enjoy them. We must utter what we feel, either by pen or pencil.

It is useless for him who has not this organ to devote himself to the Fine Arts. The mechanical operations of art, such as lithography, pattern designing, poohnah painting, and similar toys may properly exercise the talent of such an one. But on the other hand, to any one who possesses this faculty in ever so small a degree, the study of the Fine Arts is commendable. After passing over the first steps an unlimited field of pleasure is opened to him.

Photographic Glossary.

Sel d'or (Salt of Gold)—A compound salt consisting of a double hyposulphite of gold and sodium, used for fixing daguerreotype images and for toning positive proofs on paper. It is prepared by dissolving sixteen grains of neutral chloride of gold and sodium in a pint of water, and forty-eight grains of hyposulphite of soda in another pint of water, and then pouring the solution of gold into the hypo, stirring meanwhile.

Serum — The whey of milk, which, when the milk is curdled by acids, separates from the cheesy portion. Serum of milk consists of water holding in solution a peculiar saccharine substance called lactine or sugar of milk, together with certain salts, phosphates, and chlorides. Serum is employed in preparing paper for the calotype.

Silver — A well known metal of considerable importance in photography, in its combinations with chlorine, iodine, and nitric acid, forming chloride, iodide, and nitrate of silver.

Soda — The oxide of the metal sodium. Its properties are very similar to those of potash, and it is a substance of equal importance in the arts. The solid *hydrate* (caustic potash), is a white fusible substance, deliquescent, and highly alkaline. The salts of soda are of considerable importance in photography, particularly the carbonate, phosphate, and hyposulphite.

Solarisation — The destructive effect of over-exposing a photographic preparation to the action of the sun's rays.

Solution — The dissolving a solid body in a liquid, as water, alcohol, &c. Bodies are brought to the liquid state by the action of heat, &c., but do not form solutions, for which a solvent is required.

Specific Gravity — The density of a body with reference to its bulk. Thus, a cubic inch of water weighs 252·5 grains, while a cubic inch of lead weighs 2865·8 grains, therefore lead is 11·35 times heavier than water. For convenience of comparison, water is taken as the standard, and is represented by 1·000, therefore the specific gravity of lead is 11·350.

Spectrum — The solar spectrum is the coloured image of the sun, produced by the passage of its rays through a prism. The white light of the sun is decomposed into three primary and several secondary colours, which succeed each other in the following order:—red, *orange*, yellow, *green*, blue, *indigo*, *violet*, &c., the colours indicated in italics being compounds of the primaries.

Starch — Called also amidine, farina, fecula; is a component part of the grain of wheat and other cereals. It is white, tasteless, and inodorous, appearing under the form of a soft homogeneous powder, which, under the microscope, appears granular. Starch is insoluble in cold water, but forms a gelatinous mass with boiling water upon cooling, forming a very useful paste for mounting photographs with.

Stereoscope — An optical instrument invented by Professor Wheatstone, by the aid of which two plane images are seen as one in relief. It usually consists, as now made, of a rectangular, truncated, pyramidal box, with an aperture in one side to admit light to illuminate the pictures placed in the interior. Two small lenses are mounted on its summit, through which the pictures are viewed simultaneously, and are seen as one object in relief.

New Books.

The A B C of Photography, eleventh edition, with additions, including recent improvements in the art.

THE LONDON STEREOSCOPIC COMPANY, 54, Cheapside, and SIMPKIN, MARSHALL, & Co., Stationers' Hall Court.

THIS being but a new edition, does not call for any extended remarks; but we may state that it seems well calculated to carry out its professed object—that of instructing the novice how to take presentable pictures without first compelling him to learn the theoretical part of the subject. No pretensions are made to any profound scientific explanations—and, in fact, they would be out of place in so elementary a work—but with each division of the subject there is a section devoted to failures, their causes and remedies.

It is particularly adapted to those knowing nothing at all of photography, and wanting a slight insight into its mysteries.

Foreign Correspondence.

Paris, August 25, 1859.

ONE of the greatest triumphs of photographic art yet achieved is the publication of the works of Paul Delaroche, executed by Mr. Bingham, edited by M. Jules Goddé, and published by Messrs. Goupil & Co. The entire series consists of no less than eighty-six different subjects, and is published in twenty-two numbers, at twenty-five francs each, the total cost of the work being twenty pounds sterling. The pictures of M. Delaroche are mostly historical subjects, many of them being taken from English history. Among the most popular are "The Death of Queen Elizabeth," "The Princes in the Tower," "The Execution of Lady Jane Grey," "Stafford going to Execution," "Cromwell Contemplating the Corpse of Charles I." These works have tended to make Delaroche more popular in England than any other French artist. A biography of the painter, by Henri Delaroche, and a catalogue *raissonné* of his works, by M. Goddé, render this publication as complete as can be desired.

At the last meeting of our Photographic Society, M. Civiale made a communication on the diminution of time of exposure for waxed-paper, and dry collodion, and albumen. He was led to make his experiments by remarking the rapidity moist paper acquires from the presence of free nitrate of silver on the surface, and he has endeavoured to put waxed-paper (after exposure) nearly in the same conditions as wet paper, and also dry collodion and albumen in the same conditions as wet.

The sensitised paper being properly washed and dried, the time of exposure with a landscape lens (Chevalier) with small diaphragm, for a plate twelve by ten inches, is from two to four minutes and a half. This result is obtained by plunging the proof, after its exposure to light, into the sensitising bath of aceto-nitrate of silver. When the sheet is entirely covered by the liquid, at the end of about ten seconds, it is removed with pincers to the gallic acid bath—

Distilled water........................ 7 ounces,
Gallic acid.................. .... 10 grains.

Without the usual addition of water used for washing the nitrate off.

Dry waxed-paper thus treated has all the advantages and inconveniences of wet paper: a greater rapidity, added to a little more hardness and instability in the results, especially in bad weather. It is necessary to take very great precautions to avoid spots; the dishes must be perfectly clean, the paper carefully selected, and recently iodised. At present good negatives have only been obtained with paper sensitised within two days, and to avoid the mottled appearance it is best to operate with paper sensitised the same day.

Perhaps it may be advantageous to increase the proportion of acetic acid in the aceto-nitrate bath, and also to modify it a little.

It requires about forty or fifty seconds in the shade to take a portrait, on a plate twelve by ten inches, upon dry waxed-paper. The time of exposure with landscape lens, plate eight by six inches, varies from one minute to two and a half.

As to dry collodion and albumen, in rendering their surfaces moist (after exposure) by means of the sensitising bath, we arrive nearly, if not altogether, at the rapidity of wet collodion and albumen.

Perhaps there is nothing new in this suggestion, but as I do not observe that it is practised, I may say with the Parisian milliners—"there is nothing so new as that which is forgotten."

The Abbé Laborde has been testing M. Nièpce's experiments on "bottled light:" the conclusions at which he arrives are, that the existence of "persistent activity of light," and "stored-up light" cannot be substantiated.

I must commend to your attention M. Monckhoven's paper on *Pyroxyline*, as containing some important facts on the mode of preparing gun-cotton for collodion. As it is the production of an eminently practical photographer and skilful chemist, it differs essentially from the crude suggestions with which our journals abound. In his sketch of the rise and progress of collodion, he shows that M. Le Gray was the first to suggest gun-cotton in 1850, in the following passage of his *Treatise on Photography*—"I have discovered a process of photography on glass, by hydrofluoric ether and fluoride of potassium, dissolved in alcohol of forty degrees, mixed with sulphuric ether, and saturated with collodion; I then sensitise with aceto-nitrate of silver, and thus obtain pictures in the camera in five seconds in the shade; the picture is developed with a weak solution of sulphate of iron." The same year Messrs. Fry and Archer published a method of photography on collodion, which is the same as that practised at the present day, and they are justly regarded as the inventors of the process. In fact, it was impossible to employ M. Le Gray's formula, because the fluorides do not yield images, and hydrofluoric ether is a substance which cannot be said to exist. Even if M. Le Gray's mention of collodion served as the hint upon which Messrs. Fry and Archer acted, the latter have none the less merited the claim of originality in proposing a really practicable formula.

M. Poitevin, who has so stoutly contended for the "De Luynes' Prize," has presented to the Photographic Society a proof taken by him direct with typographic ink on paper, in July, 1855, and one of a series of photographic proofs taken at different epochs of the application of the process, to the perfecting of which that artist is so zealously devoted. He also exhibited proofs obtained by his gallate of iron process.

Messrs. Davanne and Girard are steadily pursuing their experimental researches on the philosophy of positive printing, which will yet require some months for completion. They fully expect to attain the object they proposed to themselves in the commencement—that of permanency and certainty in photographic printing.

Messrs. Salmon and Garnier presented a memoir upon their carbon printing process upon paper, stone, and metal, with specimens.

M. Nièpce de St. Victor is still pursuing his experiments upon the chemical changes effected by light on starch and other organic bodies. For example, starch suspended in water to which a small quantity of a metallic salt is added, and exposed for a given time to the sun's rays, is converted—first into dextrine, and then into grape sugar. M. Nièpce is convinced that in one of his experiments he obtained true cane sugar. If this statement is confirmed it will constitute one of the greatest discoveries of the age. The experiments were made in glass flasks, and the presence of the sugar was proved, not only by the aid of the ordinary tests, but also by employing the saccharometer to test its optical properties, by which it can be readily ascertained whether cane sugar or grape sugar is present. In some instances the organic matter acted upon by the metallic salt under the influence of light, appeared to be converted into a new substance, which did not exhibit to the usual tests the peculiar reactions of starch, dextrine, or sugar. It is also supposed, though not yet proved, that under certain conditions grape sugar may be converted by the agency of light into oxalic acid. J. P.

Correspondence.

AN AMATEUR'S DIFFICULTIES.

To the Editor.

Sir,—There are so many questions asked of you, that perhaps I may be excused for adding one or two to the number.

1. Do you know of a developing solution for positives that will keep for a length of time? I was shown some by a dealer in photographic goods, which he said would keep, so that a quantity might be made at one time, which seems to me a great advantage. It was highly coloured, something like pernitrate of iron.

2. I have tried the formula for obtaining pure whites, but when I poured the varnish on the white tone was considerably impaired. I am not prepared to say that the deterioration in tone was owing to the sulphuric acid which the developer contains, but it appears to me that it arose from the varnish supplying organic matter to the silver in the collodion film, thereby forming an organic compound of silver. For obtaining pure whites, nitric acid seems to me to be superior to anything that I am aware of. I have now been practising a short time, using nothing but nitric acid, both in the bath and developer, and I certainly have produced more brilliant pictures than I ever did before. The bath was nearly neutral, and seemed to have a tendency to become alkaline, producing foggy pictures. Although I say that the pictures were brilliant, yet I think there was a flatness about them—an absence of relief, which does not happen when acetic acid forms an ingredient in the bath and developer.

As far as I have observed, the fogging produced from an alkaline bath is very different from fogging from other causes, and can be easily distinguished. Fogging does not appear to me a proper term for it; for instead of "veiling" the picture like a mist, it lay in patches as if some dirty solution had been bespattered against it, and it appears to be the worst at the top of the plate, as it had been exposed in the dark slide.

Being a constant subscriber to your valuable Journal, I should take it as a great favour if you would offer a few remarks on the above.

I have been much interested with the "Letters to a Young Photographer," though I entirely failed with the "cheap John" method of toning. It seems to me, though I wish to say it modestly, to be "a penny wise and pound foolish" method, of which you, I believe, share the same opinion.—I am, yours, &c.

A WOULD-BE PHOTOGRAPHER.

Wakefield, Aug. 20th, 1859.

[1. No iron developing solution will keep for any length of time without deterioration, especially in hot weather. You will find an easily-made and economical one in a paper of Mr. Mayall's, published in one of our Spring numbers.
